Tabes Dorsalis

BASIC INFORMATION

DEFINITION

Tabes dorsalis is a form of late neurosyphilis affecting the dorsal columns of the spinal cord and peripheral nerves, characterized by paroxysmal pain, particularly in the abdomen and legs; sensory ataxia; normal strength; autonomic dysfunction; and Argyll Robertson pupils.

SYNONYMS

Posterior spinal sclerosis
Tabetic neurosyphilis
Syphilitic myeloneuropathy
Neurosyphilis

ICD-10CM CODE
A52.11 Tabes dorsalis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Rare, but increasing with HIV/AIDS
PEAK INCIDENCE: 15 to 20 yr after initial infection
PREVALENCE (IN U.S.): Rare; more common with HIV/AIDS epidemic. Ten percent of untreated patients with syphilis develop neurosyphilis, 2% to 5% of whom may develop tabes dorsalis. Relative prevalence of tabes dorsalis is reduced compared with the preantibiotic era. This may be the only clinical manifestation of neurosyphilis that has been altered during the antibiotic era.
PREDOMINANT SEX: Male

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Argyll Robertson pupils are common. The pupil reacts poorly to light but well to accommodation (light-near dissociation)
- Loss of position and vibration at ankles (wide-based gait, inability to walk in the dark, sensory ataxia)
- Loss of deep pain sensation, resulting in deep foot ulcers
- Degenerative joint disease (Fig. E1), especially in knees, caused by severe neuropathy (Charcot joints)
- Normal strength with areflexia in the legs
- Lightning pains in the legs
- Severe intermittent visceral pains, such as gastrointestinal and laryngeal (visceral crises)
- Autonomic dysfunction (urinary and fecal incontinence due to sphincter dysfunction)

ETIOLOGY

Infectious *(Treponema pallidum).* Neurosyphilis occurs as a consequence of treponemal penetration of the blood-brain barrier and destruction of adjacent neural tissue, sometimes coupled with cerebral infarction due to meningovascular disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vitamin B_{12} deficiency (subacute combined degeneration of the spinal cord)
- Vitamin E deficiency
- Chronic nitrous oxide abuse
- Spinal cord neoplasm (involving conus medullaris)
- Lyme disease

WORKUP

Thorough neurologic history and examination

LABORATORY TESTS

- Lumbar puncture: The diagnosis of neurosyphilis requires a CSF mononuclear pleocytosis of 20 WBC/μL or a reactive Venereal Disease Research Laboratory (VDRL) or a positive intrathecal *T. pallidum* antibody index. Pleocytosis is less specific in patients with HIV due to HIV-related meningitis.
- False-positive serum RPR may occur in Lyme disease, nonvenereal treponematoses, genital herpes simplex, pregnancy, systemic lupus erythematosus, alcoholic cirrhosis, scleroderma, and mixed connective tissue disease.
- All patients with syphilis should be tested for HIV.
- Persons who are HIV positive are at increased risk of developing neurosyphilis. A new development in the detection of neurosyphilis in patients who are HIV positive is the use of the B-cell chemoattractant chemokine (CXC motif) ligand 13 as a CSF marker.

IMAGING STUDIES

Not necessary if diagnosis confirmed clinically and serologically

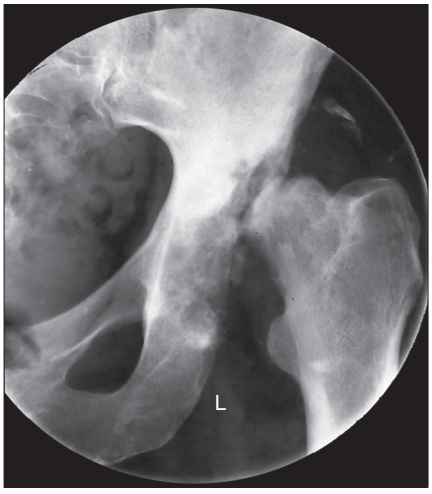

FIG. E1 Neuropathic hip secondary to tabes dorsalis. (Courtesy Dr. I. Watt. From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

TREATMENT

ACUTE GENERAL Rx

- CDC guidelines: Aqueous crystalline penicillin G 18 to 24 million units per day, administered as 3 to 4 million units IV every 4 hours, or continuous infusion for 10 to 14 days; or if adherence can be ensured, penicillin G procaine, 2.4 million units IM daily, plus probenecid 500 mg orally four times a day for 10 to 14 days
- If patient is penicillin allergic, either desensitize to penicillin or obtain an infectious disease (ID) consultation.
- Many of the symptoms—degenerative neuropathic joint disease, lightning pains—persist after treatment.

CHRONIC Rx

- Physical therapy
- Analgesics, carbamazepine, gabapentin, or steroids may help lightning pain
- Supportive care (wheelchair, toileting issues, etc.)

DISPOSITION

- Close follow-up required. Repeat lumbar puncture is recommended every 6 mo until CSF pleocytosis normalizes. If pleocytosis does not normalize in 6 mo or CSF is still abnormal in 2 yr, repeat treatment. Serologic criterion for response to therapy is a fourfold or greater decrease in VDRL titer over 6 to 12 mo.
- Further indication for retreatment: If there is a fourfold increase in titers or a failure of titers >1:32 to decrease at least fourfold by 6 to 12 mo.

REFERRAL

- Joint replacement in moderate cases
- ID consult for patients with penicillin allergy

PEARLS & CONSIDERATIONS

COMMENTS

- Diagnosis should be considered in all patients with a progressive neuropsychiatric disorder with signs of spinal cord dysfunction and peripheral neuropathy.
- Penicillin does not improve late neurosyphilitic syndromes but usually halts their progression.

BASIC INFORMATION

DEFINITION

Takayasu arteritis is a large-vessel vasculitis that primarily affects the aorta and its main branches. Chronic inflammation of involved vessels commonly leads to stenosis, occlusion, dilation, and aneurysms in the arterial wall.

SYNONYMS

Pulseless disease
Aortitis syndrome
Aortic arch arteritis
Nonspecific aortoarteritis

ICD-10CM CODE
M31.4 Aortic arch syndrome [Takayasu]

EPIDEMIOLOGY & DEMOGRAPHICS

In the U.S., the incidence is 2.6 per 1 million people. The highest prevalence of Takayasu arteritis has been described in Japan, where all cases of Takayasu arteritis are registered by the government, and it has been estimated that 100 to 200 new cases occur each yr.

The female:male ratio is 8:1. Age of onset is between 10 and 40 yr with three quarters of patients presenting between the ages of 10 and 20 yr.

GENETICS: Some HLA alleles, including HLA-B52, HLA-B39, and HLA-B67, have been reported to be associated with Takayasu.

CLINICAL PRESENTATION & PHYSICAL FINDINGS

Takayasu arteritis manifests with clinically nonspecific signs and symptoms of systemic inflammation, including general fatigue, weight loss, generalized arthralgias and myalgias, and low-/high-grade fever. These symptoms are usually subacute, which leads to delay in the diagnosis from mos to yrs. Vascular symptoms are rare at presentation, and localized symptoms and signs vary depending on the location of the affected arteries.

- Table E1 summarizes common symptoms and signs in Takayasu arteritis. "Red flags" for Takayasu arteritis are summarized in Table E2.
- The occlusive stage of Takayasu arteritis may progress to stenosis or aneurysm of the aorta and its primary branches, and may manifest as a variety of clinical signs and symptoms, such as:
  1. Arm or leg claudication, weakness, and numbness
  2. Amaurosis fugax, diplopia, headache, orthostasis, vertigo, memory loss, or syncope
  3. Angina or myocardial infarction
  4. Vascular bruits of the carotid artery, subclavian artery, and aorta
  5. Discrepancy of blood pressures between the upper extremities, typically of ≥10 mm Hg
  6. Diminished or absent pulses, ischemic ulcerations, or gangrene in advanced disease
  7. Hypertension
  8. Retinopathy
  9. Aortic insufficiency as a result of aortic root dilatation and aneurysm formation
  10. Weakness of the arterial walls may give rise to localized aneurysms/dissection.
  11. Dyspnea or hemoptysis
  12. Skin lesions similar to erythema nodosum
- Gastrointestinal (GI) symptoms (abdominal pain, diarrhea, and GI bleed) secondary to mesenteric artery ischemia

ETIOLOGY & PATHOGENESIS

The cause of Takayasu arteritis is poorly understood. Cell-mediated mechanisms (cytotoxic T cell, macrophage, natural killer cells, and others) and cytokine release (such as tumor necrosis factor-alpha [TNF-α], interleukin-6 [IL-6], and interferon-gamma [IFN-γ]) are thought to be important to the pathogenesis. Both pathways contribute to the induction and amplification of inflammation and tissue injury.

- Infiltration by inflammatory cells (lymphocytes, macrophages, and multinucleated giant cells) into the vasa vasorum and media of the large elastic arteries (Fig. E1) leads to production of matrix metalloproteinases (MMP), which cause destruction of elastic fibers in the arterial wall, neovascularization, and other inflammatory changes. An intermediate stage, driven in part by TNF-alpha, leads to mucopolysaccharide deposition and proliferation of fibroblasts and smooth muscle cells, causing intimal hypertrophy.
- With chronic disease, inflammatory lesions progress to either thick fibrotic calcified narrowings (≥90% of cases) or aneurysms if fibrosis is insufficient and the arterial wall is instead thinned and dilated (≥25% of cases).
- Infection, in particular, tuberculosis, has been implicated in the pathogenesis, with several studies reporting an increased incidence of caseating granulomas in patients with Takayasu arteritis. Additional immunologic studies lend support to a pathogenic role of CD4 and CD8 T cells in this patient population.

DIAGNOSIS

Diagnostic criteria for Takayasu arteritis were established by the American College of Rheumatology in 1990. A diagnosis is made if at least three of the six criteria are present; this

TABLE E1 Common Symptoms and Signs (%) in Takayasu Arteritis

	Study					
Symptom/Sign	**Japan (n = 52)**	**India (n = 106)**	**China (n = 530)**	**Korea (n = 129)**	**U.S. (n = 60)**	**Mexico (n = 107)**
Fatigue/constitutional	27%	—	—	34%	43%	78%
Weight loss	—	9%	—	11%	20%	22%
Musculoskeletal	6%	5%	—	—	53%	53%
Claudication	13%	—	25%	21%	90%	29%
Headache	31%	44%	—	60%	42%	57%
Visual changes	6%	12%	10%	20%	30%	8%
Syncope/dizziness	40%	26%	14%	36%	35%	13%
Palpitations	23%	19%	—	23%	10%	43%
Dyspnea	21%	26%	11%	42%	—	72%
Carotidynia	21%	—	—	2%	32%	—
Hypertension	33%	77%	60%	40%	35%	72%
Bruit	—	35%	58%	37%	80%	94%
Decreased pulses	62%	—	37%	55%	60%	96%
Asymmetric blood pressure	—	—	—	—	47%	—

From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.

results in a sensitivity of 91% and specificity of 98%. The criteria are:

- Age of disease onset <40 yr
- Claudication of the extremities
- Decreased brachial artery pulse
- Systolic blood pressure difference ≥10 mm Hg between left and right arms
- Bruit over one or both of the subclavian arteries or the abdominal aorta
- Abnormal arteriogram, not related to arteriosclerosis or fibromuscular dysplasia

TABLE E2 "Red Flags" for Takayasu Arteritis

In patients younger than 40 yr, the following may be indicative of TA:
Unexplained acute-phase response (raised ESR and/or CRP)
Carotidynia
Hypertension
Discrepant blood pressure between the arms (>10 mm Hg)
Absent or weak peripheral pulse or pulses
Limb claudication
Arterial bruit
Angina

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

DIFFERENTIAL DIAGNOSIS

Table E3 describes pathologic characteristics of selected forms of vasculitis. Other causes of inflammatory arteritis must be excluded:

- Temporal arteritis (giant cell arteritis)
- Atherosclerosis
- Infectious aortitis
- Syphilis
- Tuberculosis
- Systemic lupus erythematosus
- Rheumatoid arthritis
- Buerger disease
- Behçet disease
- Marfan syndrome
- Ehlers-Danlos syndrome

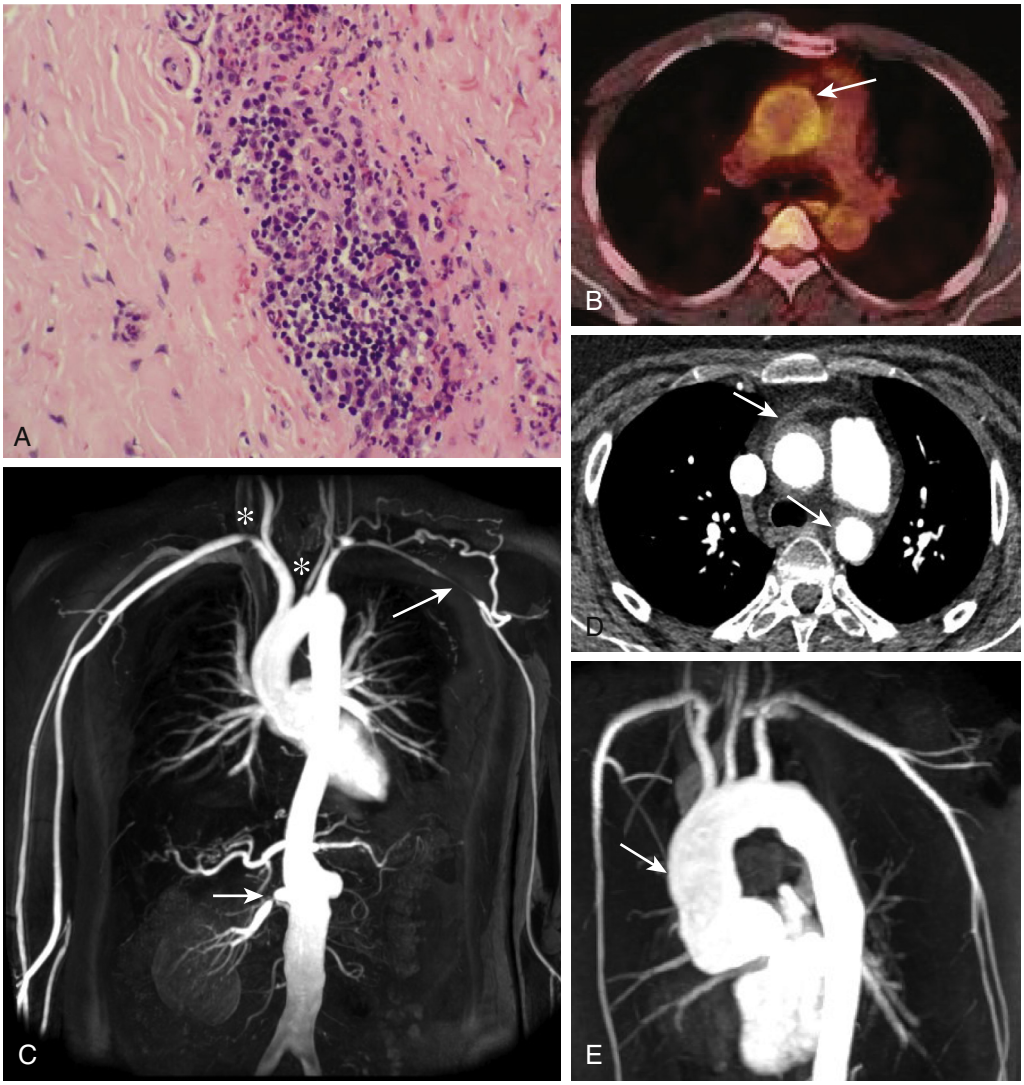

FIG. E1 Takayasu arteritis A, Hematoxylin-eosin staining of a common carotid artery biopsy specimen obtained at surgery shows a focal mixed mononuclear cell inflammatory infiltrate with a multinucleated giant cell. **B,** ^{18}FDG-PET-CT scan demonstrating uptake in the aortic arch *(arrow)*, consistent with active arteritis. **C,** Magnetic resonance angiogram (MRA) demonstrating stenosis of the left subclavian artery with collateral formation *(long arrow)*, proximal stenoses in the right subclavian and left common carotid arteries *(stars)*, proximal stenosis in the right renal artery *(short arrow)*, and an atrophic left kidney. **D,** Computed tomography angiogram demonstrating thickening of the wall of the ascending and descending aorta *(arrows).* **E,** MRA revealing severe dilatation of the ascending aorta *(arrow)* requiring aortic valve replacement. - Cogan syndrome
- Kawasaki disease
- Spondyloarthropathies
- Fibromuscular dysplasia
- Relapsing polychondritis

WORKUP

Any young patient with findings of absent pulses and loud bruits merits a workup for Takayasu arteritis. There are no diagnostic laboratory tests to diagnose Takayasu arteritis. Nonspecific inflammatory biomarkers, including C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR), are useful markers for diagnosis, but normal values shouldn't be used to rule out the disease. In most patients, the diagnosis is made by clinical findings and imaging of the arterial branches. Advanced imaging modalities, including contrast-enhanced magnetic resonance angiography (MRA) and computed tomography angiography (CTA), allow for not only early diagnosis but also detailed assessment of vascular lesions. Three-dimensional reconstructions of the whole aorta and neck arteries using CTA are especially useful for surveying lesions. Ultrasound and FDG-PET are commonly used for diagnosis as well as in serial monitoring of disease activity. Catheter-based angiography is used to rule out ischemia and to measure core blood pressure when all four limbs arterial stenosis prevent accurate blood pressure measurement.

LABORATORY TESTS

- ESR and serum CRP levels are usually but not always elevated.
- A CBC may reveal a normal or elevated white blood cell count as well as anemia.
- Immunologic studies may include elevated immunoglobulins (IgG and IgA) and complement components (C3 and C4).
- Hypercoagulation and increase in platelet aggregation.
- Recent studies have attempted to establish a link between elevated levels of various interleukins and other inflammatory markers and active disease.

IMAGING STUDIES

- Imaging of the entire aorta and major branch vessels using angiography, CTA, or MRA.
- CTA can detect changes in the vessel wall and provide an accurate representation of luminal diameters.
- MRA provides information on vessel lumen and wall thickening, cardiac morphology and function, and myocardial tissue characterization.
- Angiography can show the narrowing of the aorta and its branches, aneurysm formation, poststenotic dilation, and the development of any collateral circulation. Angiographic findings are classified into five major types:
  1. Type I: Lesions that involve only branches of the aortic arch
  2. Type IIa: Lesions that involve the ascending aorta, the aortic arch, and its branches
  3. Type IIb: Lesions from IIa plus the thoracic descending aorta
  4. Type III: Lesions that involve the thoracic descending aorta, abdominal aorta, and/or renal arteries
  5. Type IV: Lesions that involve the abdominal aorta and/or renal arteries
  6. Type V: Lesions that involve the entire aorta and its branches
- Chest radiography: Pathologic changes of the aorta are often visible, with areas of alternating stenosis and dilation seen. Segmental calcification outlining areas of aortic narrowing is characteristic of Takayasu disease.
- Ultrasound: Carotid, thoracic, and abdominal ultrasound are useful adjunctive imaging studies to diagnose the occlusive disease that results from Takayasu arteritis. The addition of Doppler is helpful to assess blood flow and absent pulses.
- Positron emission tomography using radioisotope fluorodeoxyglucose (FDG-PET) as a marker for tissue with high glucose uptake has shown promising results in terms of specificity and sensitivity. The yield of using PET scans to measure disease activity is still under study.

Rx TREATMENT

Treatment of Takayasu arteritis consists of two parts: Induction and maintenance of remission and management of arterial complications.

ACUTE GENERAL Rx

High-dose glucocorticoids are first-line therapy for suppressing systemic symptoms and stopping disease progression. Prednisone (1 mg/kg/day, up to a maximum daily dose of 60 to 80 mg) can be used for 3 mo or intravenous steroids can be administered initially.

Attempts to taper prednisone can be made with resolution of constitutional symptoms, significant decline in the ESR and C-reactive protein levels, and in accordance with imaging studies.

Because of steroids' side effects and the high rate of relapse while tapering, it is recom-

TABLE E3 Pathologic Characteristics of Selected Forms of Vasculitis

	Takayasu Arteritis	Polyarteritis Nodosa	Wegener Granulomatosis	Churg-Strauss Syndrome	Henoch-Schönlein Purpura	Cutaneous Leukocytoclastic Angiitis
Vessels involved	Elastic (large) or muscle (medium-sized) arteries	Medium-sized and small muscle arteries	Small arteries and veins; sometimes medium-sized vessels	Small arteries and veins; sometimes medium-sized vessels	Capillaries, venules, arterioles	Capillaries, venules, arterioles
Organ involvement	Aorta, aortic arch and major branches, pulmonary arteries	Skin, peripheral nerve, gastrointestinal tract, other viscera	Upper respiratory tract, lungs, kidneys, skin, eyes	Upper respiratory tract, lungs, heart, peripheral nerves	Skin, joints, gastrointestinal tract, kidneys	Skin, joints
Type of vasculitis and inflammatory cells	Granulomatous with some giant cells; fibrosis in chronic stages	Necrotizing, with mixed cellular infiltrate	Necrotizing or granulomatous (or both); mixed cellular infiltrate plus occasional eosinophils	Necrotizing or granulomatous (or both); prominent eosinophils and other mixed infiltrate	Leukocytoclastic, with some lymphocytes and variable eosinophils; IgA deposits in affected tissues	Leukocytoclastic, with occasional eosinophils

IgA, Immunoglobulin A.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

mended to use a glucocorticoid sparing agent at the time prednisone is prescribed. Commonly used second agents include:

- Leflunomide
- Methotrexate
- Mycophenolate mofetil
- Azathioprine
- Tocilizumab
- Anti-TNF agents
- Cyclophosphamide

CHRONIC Rx

- Patients with Takayasu arteritis are monitored closely for signs of relapse and disease complications with clinical assessment, inflammatory biomarkers (e.g., ESR and CRP), and imaging. Multiple indexes exist for the assessment of disease activity, including the NIH criteria for active disease, the Disease Extent Index-Takayasu (DEI.Tak), and the Indian Takayasu Arteritis Score (ITAS).
- Percutaneous angioplasty or bypass grafts should be considered for irreversible arterial stenoses with severe ischemia (cardiac or cerebral), severe hypertension in renal artery stenosis, or aneurysmal enlargement with risk of rupture. Five-yr arterial complication rate after surgical or endovascular revascularization is around 40%. The likelihood of complications increases sevenfold when inflammation is present at the time of revascularization.
- Aortic regurgitation may require valve replacement or repair by surgery, although the need to manipulate inflamed, friable tissue can lead to complications such as valvular detachment after replacement.
- Treatment of hypertension in patients with Takayasu arteritis can be difficult, especially because there is usually concurrent glucocorticoid therapy and there is the potential for renovascular hypertension. Special monitoring should be employed when using ACE inhibitors due to the high frequency of renal artery stenosis in this population.

DISPOSITION

- Immunosuppressant therapy may achieve clinical remission.
- With the addition of a second agent for patients with treatment resistance or relapse, approximately half of patients will achieve remission.
- Quality of life is comparable to that of patients with rheumatoid arthritis or ankylosing spondylitis.
- In the absence of major complications (MI, stroke, severe hypertension, heart failure, and aneurysm), 5-yr survival rates reach 80% to 90%. In the presence of major complications, 5-yr survival is 50% to 70%.
- Death can occur suddenly from a ruptured aneurysm, a myocardial infarction, or a cerebrovascular accident.

Pregnancy may exacerbate cardiovascular complications and can increase the risk for maternal and fetal morbidity and mortality. Heart failure, embolism, and thrombosis are common complications during pregnancy. If a pregnant woman is diagnosed with the disease, oxytocin should be injected to the corpus uteri directly (when needed), and the intravenous route should be avoided. It is important to maintain the mother's blood pressure in a stable range and to avoid fluctuations in hemodynamics.

REFERRAL

Whenever the diagnosis of vasculitis is suspected, a rheumatology consultation is appropriate. Vascular surgery and cardiology consultations are recommended for any evidence of carotid, peripheral, or coronary artery disease or if a large abdominal aneurysm is found.

PEARLS & CONSIDERATIONS

With long-term glucocorticoid use, consider measures to protect against bone loss. Bisphosphonates have been studied prospectively with corticosteroid use in this fashion; remember to ensure adequate dietary calcium and vitamin D intake as well.

COMMENTS

- No studies have proved that treatment results in regression of stenosis, although there are limited case reports describing the return of pulses with treatment.
- Only one fifth of patients have a self-limited course. The majority show a progressive or relapsing remitting course that requires long-term immunosuppressive therapies.
- Although short-term prognosis of the disease is favorable, long-term prognosis depends on the incidence of complications and the presence of progressive course. The presence of both major complications along with progressive course is associated with the worst prognosis. The prognosis and vascular complications of Takayasu arteritis are improving. Fatal or serious complications have diminished in the past decade.

BASIC INFORMATION

DEFINITION

Takotsubo cardiomyopathy, also known as stress cardiomyopathy (SC), is a syndrome characterized by transient systolic and diastolic dysfunction with a characteristic ballooning of the apical and/or mid segments of the left ventricle (LV). It mimics acute myocardial infarction (MI), but there is no evidence of obstruction of an epicardial coronary artery. Typically, but not always, it is preceded by severe illness or intense emotional, physical, or psychological stress. Initially described in the 1990s in Japan, the systolic LV on left angiogram has a distinctive shape similar to a *tako-tsubo* pot with a narrow neck and round bottom, used by fishermen to trap octopi. The variants of SC include apical (81.7%), midventricular (14.6%), basal/reverse takotsubo (2.2%), and focal (1.5%).

SYNONYMS

Stress cardiomyopathy (SC)
Left ventricular apical ballooning syndrome (LVABS)
Ampulla cardiomyopathy
Broken heart syndrome

ICD-10CM CODE
I51.81 Takotsubo syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: An estimated 15 to 30 new cases per 100,000 per yr
PREVALENCE: About 1% to 2% of patients presenting with troponin-positive acute coronary syndrome (ACS) have SC.
PREDOMINANT SEX AND AGE: On presentation, 90% are females, and 80% are females >50 yr of age. Mean age of presentation is 68.8 yr.
RISK FACTORS: SC can be triggered by severe medical illness, intense emotional psychosocial stress or physical stress (death of loved ones, domestic abuse, fierce arguments, financial hardships, severe pain, natural disasters, etc.), or chronic stress/distress. A positive life event (happy heart syndrome) also can cause SC. Familial case series have raised the possibility of a genetic predisposition.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute substernal chest pain, dyspnea, and syncope are the most common presenting complaints (International Takotsubo Registry study).
- On physical examination, a systolic ejection murmur (due to left ventricular outflow tract obstruction and mitral regurgitation) may be present.
- SC can manifest as heart failure (30%), ventricular arrhythmias, cardiogenic shock (10%), or sudden cardiac death.

ETIOLOGY

The proposed mechanisms for SC include the following:

- In postmenopausal women, estrogen deficiency leads to endothelial vasomotor dysfunction. Lack of endothelial-dependent vasodilation causes excessive coronary vasoconstriction.
- Increased catecholamine from an acute event can be directly toxic to the myocardium. The increased density of beta-adrenoreceptors in the apex makes it more sensitive to catecholamine and accounts for the apical ballooning.
- Impaired microvascular perfusion resulting in ischemic stunning.
- Fig. 1 depicts the interplay among triggers, pathogenic factors, and predisposing factors in SC.

DIAGNOSIS

Mayo Clinic proposed criteria (2008) for diagnosis of SC: All four criteria required to make diagnosis.

- Transient wall motion abnormalities that extend beyond a single epicardial vascular distribution (Fig. 2). A stressful trigger is often, but not always, present
- Absence of obstructive coronary disease or angiographic evidence of acute plaque rupture
- New ECG abnormalities (ST-segment elevation and/or T-wave inversion) or modest elevation in cardiac troponins
- Absence of pheochromocytoma or myocarditis

DIFFERENTIAL DIAGNOSIS

- Acute coronary syndrome
- Cardiac syndrome X/microvascular angina
- Prinzmetal angina
- Acute myocarditis
- Cocaine cardiomyopathy
- Cardiomyopathy associated with pheochromocytoma

WORKUP

- A high index of suspicion is required when a postmenopausal woman presents with ACS after intense stress.
- Cardiology consult should be immediately obtained.
- Obstructive coronary artery disease needs to be ruled out.

LABORATORY TESTS

- Cardiac biomarkers (troponin, CK-MB) are often modestly elevated.
- Cardiac natriuretic peptide (brain natriuretic peptide [BNP] and pro-BNP) levels are also commonly elevated.

IMAGING STUDIES

- ECG: ST elevation in precordial leads (reciprocal changes typically absent), T-wave inversions (which may be dramatic) in the anterior or lateral leads, QT prolongation, and abnormal Q waves.
- Echocardiography (ECHO) typically shows the characteristic apical ballooning. Contrast ECHO is quite useful to exclude apical thrombus.
- Obstructive coronary artery disease should be excluded with a coronary angiogram.
- Cardiac magnetic resonance imaging (Fig. 3) can show the absence of late gadolinium enhancement (seen in MI).
- Coronary computed tomography angiography may help evaluate for stenosis in epicardial coronary arteries in specific clinical settings (e.g., poor MRI acoustic windows).

COMPLICATIONS

- Approximately 20% have in-hospital complications including heart failure, cardiogenic shock requiring mechanical support, life-threatening arrhythmias, acute mitral regurgitation, LV outflow tract (LVOT) obstruction, free wall rupture, and death.
- Due to the Venturi effect, mitral valve systolic anterior motion could cause LVOT obstruction and mitral regurgitation (14% to 45% of patients), which further impede LV systolic function.

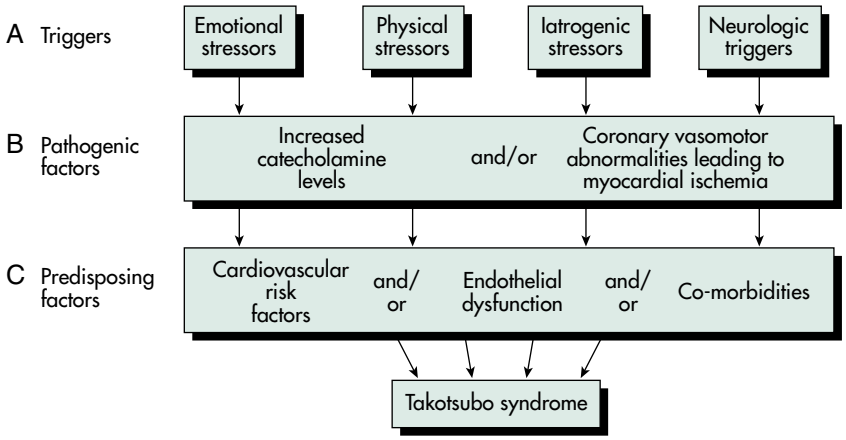

FIG. 1 The interplay among triggers, pathogenic factors, and predisposing factors in Takotsubo disease. (From Pelliccia F et al: Takotsubo syndrome [stress cardiomyopathy]: an intriguing clinical condition in search of its identity, *Am J Med* 127:699-704, 2014.)

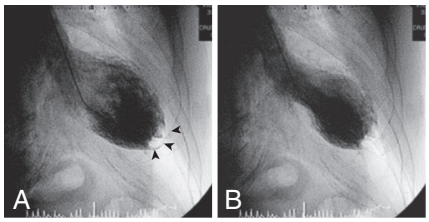

FIG. 2 A and **B,** Left ventriculogram showing apical ballooning characteristic of stress-induced cardiomyopathy. (From Mitsuma W et al: *JACC* 51[1]: cover, 2008.)

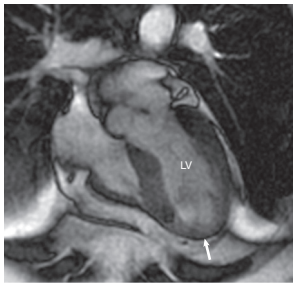

FIG. 3 Takotsubo cardiomyopathy. The patient was a 58-yr-old woman who was referred for cardiovascular magnetic resonance (CMR) after a coronary angiogram revealed no obstructive disease despite the presence of ST-segment elevations on electrocardiogram and positive biomarker assays. A diagnosis of Takotsubo cardiomyopathy was made on the basis of the CMR image, which shows LV apical akinesis and ballooning (*arrow*). *LV,* Left ventricle. (From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.)

- Arrhythmias (25%) include supraventricular tachycardia and ventricular arrhythmias.
- Systemic thromboembolism and increased risk of stroke.
- Intramyocardial hemorrhage and rupture.

Rx TREATMENT

Initially, patients should be treated for presumptive acute coronary syndrome until this is excluded.

NONPHARMACOLOGIC THERAPY

Supportive care such as the elimination of the physical or emotional trigger is important.

ACUTE GENERAL Rx

- Hemodynamically stable: Treat with diuretics, vasodilators, and venodilators (nitroglycerin, nitroprusside).
- Cardiogenic shock *without* LVOT obstruction: Vasopressor (phenylephrine, vasopressin) and inotropic support (dobutamine, milrinone, dopamine) may be required. When treatment is refractory to medical therapy, percutaneous and surgical mechanical circulatory support will be required.
- Cardiogenic shock *with* LVOT obstruction: Increase preload by leg elevation and fluid resuscitation if no significant pulmonary congestion. Avoid inotropic agents, since increased basal contractility will increase the LVOT obstruction. Beta blockers can improve the obstruction. Phenylephrine should be used cautiously because it could increase the after-load and thus increase the gradient.

CHRONIC Rx

- 3 to 6 mo of guideline-directed medical therapy for heart failure with reduced ejection fraction (beta blockers, ACE inhibitors, angiotensin II receptor blocker, aldosterone antagonist, angiotensin receptor-neprilysin inhibitor)
- Repeat ECHO (in 4 to 6 wk) to ensure normalization of systolic function.
- 3 mo of anticoagulation is suggested if an intraventricular thrombus is detected.

DISPOSITION

- Carries a favorable prognosis compared to STEMI or NSTEMI; in-hospital mortality is up to 5%. The recurrence rate is around 2% to 4% per yr.
- In a Medicare cohort, patients ≥85 yr of age had higher in-hospital, 30-day, 1-yr mortality, and 30-day readmission rates; hence, the need for good discharge planning is key.

REFERRAL

Follow up with a cardiologist.

PEARLS & CONSIDERATIONS

COMMENTS

- The term *takotsubo* is the Japanese name for an octopus trap (*tako-tsubo*), which has a similar shape of the LV in systole during a left ventriculogram (see Fig. 2).
- Patients with takotsubo cardiomyopathy have a higher prevalence of neurologic or psychiatric disorders than those with an acute coronary syndrome.

PREVENTION

Minimizing stress may reduce incidence but no data to support this.

Tapeworm Infestation PTG

BASIC INFORMATION

DEFINITION

Four species of adult tapeworm (cestodes) may infect humans as the definitive host: *Taenia saginata* (beef tapeworm), *Taenia solium* (pork tapeworm), *Diphyllobothrium latum* (fish tapeworm), and *Hymenolepis nana* (dwarf tapeworm). In addition, several tapeworms (*T. solium, T. crassiceps, T. multiceps*) can infect human tissue in their larval form, resulting in cysticercosis. Others infect in their intermediate forms, resulting in hydatid disease (see "Echinococcosis" in Section I). Table 1 describes common cestode parasites of humans, their typical vectors, and their usual symptoms.

SYNONYM

Cysticercosis (larval infection by *T. solium*)

ICD-10CM CODES

B68.0	*Taenia solium* taeniasis
B68.1	*Taenia saginata* taeniasis
B68.9	Taeniasis unspecified
B70.0	Diphyllobothriasis
B71.0	Hymenolepiasis
B71.9	Cestode infection, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Diagnosed primarily in immigrants, particularly those from Latin America and Southeast Asia
- Varies widely by country of origin and dietary practices

PREVALENCE (IN U.S.):

- *T. saginata:* <0.1%
- *D. latum:* <0.05%
- *T. solium:* <0.1%
- *H. nana:* Sporadic, often in setting of outbreak

PREDOMINANT SEX: Equal sex distribution

PREDOMINANT AGE:

- *T. saginata, T. solium, D. latum:* 20 to 39 yr of age
- *H. nana* in setting of institution outbreaks: Children

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Adult worms:

- Attach to bowel mucosa via suckers, hooks, or grooves depending on species
- Feed and grow, producing digestive/body/reproductive segments called proglottids
- Cause minimal or no symptoms or sequelae but occasionally can cause nausea, anorexia, or epigastric pain

Cysticercosis: Larval infection by *T. solium*:

- Mass lesions of brain (neurocysticercosis), soft tissue, viscera
- Neurocysticercosis may cause seizures, hydrocephalus (due to ventricle obstruction)

Prolonged infection with *D. latum*:

- Vitamin B_{12} deficiency
- Megaloblastic anemia

ETIOLOGY

TAPEWORM:

- Adult worms consist of a head (scolex), neck, and hundreds or thousands of proglottids. Each proglottid contains male and female reproductive organs, including eggs.
- Adult worm resides in small or large bowel; proglottids and eggs are passed in stool.
- *T. saginata* may produce up to 100,000 eggs/proglottid and *T. solium* up to 50,000 eggs/proglottid.
- Eggs are ingested by the animal intermediate host (Fig. 1).
- Eggs hatch into larvae.
- Larvae perforate the host intestinal wall and disseminate into skeletal muscle, brain, viscera.
- Develop into cysticerci (scolex inside a cyst) over several wk.
- Humans eat infected beef *(T. saginata),* pork *(T. solium),* or fish *(D. latum).*
- Larval scolex attaches to intestinal wall and matures into adults within the GI lumen.
- *H. nana* infection is acquired by ingesting eggs in human or rodent feces.

CYSTICERCOSIS:

- Humans ingest eggs of *T. solium* in food contaminated with human feces that contain the eggs.
- Eggs hatch into larvae in gut and cross intestinal wall.
- Larvae disseminate widely through tissues (particularly soft tissue and CNS) forming cystic lesions containing either viable or nonviable larvae.

DIAGNOSIS

WORKUP

- Stool examination for eggs or proglottids (tapeworm):
  1. Eggs of *Taenia* spp. cannot be differentiated by microscopy, but the species can be identified through examination of the proglottids in stool.
  2. Eggs of *Taenia* spp. are round and measure 30 to 40 μm.
- Cerebral noncontrast CT scan and MRI (neurocysticercosis)
- Serum antibody with ELISA confirmatory testing recommended for neurocysticercosis
- Confirmatory serologic test is enzyme-linked immunotransfer blot (EITB), as ELISA has poor sensitivity/specificity
- CBC may show eosinophilia

TABLE 1 Common Cestode Parasites of Humans, Their Typical Vectors, and Their Usual Symptoms

Parasite Species	Developmental Stage Found in Humans	Common Name	Transmission Source	Symptoms Associated with Infection
Diphyllobothrium latum	Tapeworm	Fish tapeworm	Plerocercoid cysts in freshwater fish	Usually minimal; with prolonged or heavy infection, vitamin B_{12} deficiency
Hymenolepis nana	Tapeworm, cysticercoids	Dwarf tapeworm	Infected humans	Mild abdominal discomfort
Taenia saginata	Tapeworm	Beef tapeworm	Cysts in beef	Abdominal discomfort, proglottid migration
Taenia solium	Tapeworm	Pork tapeworm	Cysticerci in pork	Minimal
Taenia solium (Cysticercus cellulosae)	Cysticerci	Cysticercosis	Eggs from infected humans	Local inflammation, mass effect; if in central nervous system, seizures, hydrocephalus, arachnoiditis
Echinococcus granulosus	Larval cysts	Hydatid cyst disease	Eggs from infected dogs	Mass effect leading to pain, obstruction of adjacent organs; less commonly, secondary bacterial infection, distal spread of daughter cysts
Echinococcus multilocularis	Larval cysts	Alveolar cyst disease	Eggs from infected canines	Local invasion and mass effect leading to organ dysfunction; distal metastasis possible
Taenia multiceps	Larval cysts	Coenurosis, bladder worm	Eggs from infected dogs	Local inflammation and mass effect
Spirometra mansonoides	Larval cysts	Sparganosis	Cysts from infected copepods, frogs, snakes	Local inflammation and mass effect

Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

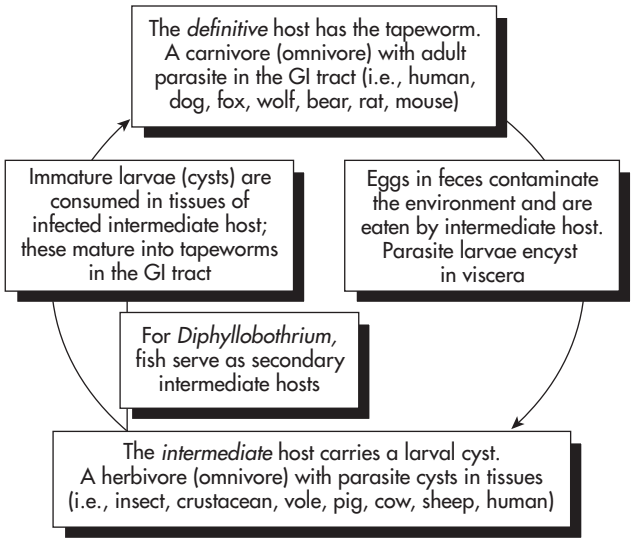

FIG. 1 Cestode parasites alternate larval and adult stages in two different hosts. *GI,* Gastrointestinal. (Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.)

IMAGING STUDIES

- Tapeworm: Incidental finding on upper GI series
- Neurocysticercosis:
  1. Cerebral cysts are readily demonstrated by CT scan or MRI.
  2. Calcified lesions are an incidental finding.

Rx TREATMENT

ACUTE GENERAL TREATMENT

- All adults and children with intestinal tapeworm infections should be treated with a single oral dose of praziquantel.
  1. *T. solium:* 5 to 10 mg/kg
  2. *T. saginata:* 5 to 10 mg/kg
  3. *D. latum:* 5 to 10 mg/kg
  4. *H. nana:* 25 mg/kg and a repeat dose 7 to 10 days later if heavy infection
- Praziquantel acts by causing changes in the teguments of the worms, allowing increased permeability to calcium ions, which then accumulate inside worm and cause paralysis.
- Repeat stool screening at 1 and 3 mo to confirm cure.
- Can use purgatives adjunctively to hasten clearance of deceased worms from intestine.
- An alternative therapy to praziquantel for fish, beef, or pork tapeworm infections is niclosamide, 2 g PO once for adults or 50 mg/kg orally once for children. For *H. nana* infections alternative is for adults: niclosamide 2 g PO × 7 days and for children 11 to 34 kg: niclosamide 1 g PO on day 1 and then 500 mg/day for 6 days and 1.5 g for children over 34 kg PO on day 1 and then 1 g/day for 6 days.
- Therapy that may be considered for symptomatic cysticercosis:
  1. May regress spontaneously (i.e., no treatment, also okay for calcified parenchymal neurocysticercosis)
  2. Surgery, especially in cases of ventricular obstruction (neurocysticercosis)
  3. Albendazole 15 mg/kg/day (maximum: 1200 mg) PO for 10 to 14 days plus
  4. Praziquantel 50 mg/kg/day PO for 10 to 14 days plus
  5. Dexamethasone: 0.1 mg/kg/day often beginning 1 to 3 days before antiparasitic therapy ×10 to 14 days, plus/minus
  6. Antiseizure medication ×1 yr. Use of steroids in neurocysticercosis may reduce CNS inflammation and increase levels of albendazole in CNS.
  7. If increased intracranial pressure is present, treat it alone before considering antiparasitic therapy
- Medical therapy second line with:
  1. Ocular infections.
  2. Cerebral infections in which local inflammation caused by destruction of the parasite may cause significant damage/inflammation (e.g. 4th ventricle infection).
- Adjunctive antiepileptics may be necessary for neurocysticercosis.

CHRONIC TREATMENT AND PREVENTION

- Retreatment if required
- Avoidance of undercooked pork, meat, or fish
- Cysticercosis: Proper hand washing, proper disposal of human waste

DISPOSITION

- Neurologic follow-up for patients with neurocysticercosis
- Ophthalmologic follow-up for patients with ocular involvement

REFERRAL

Patients treated for neurocysticercosis should be evaluated by a physician experienced in managing this infection if possible.

PEARLS & CONSIDERATIONS

COMMENTS

T. solium is the most dangerous of the tapeworms because of the potential for cysticercosis by means of autoinfection.

Tardive Dyskinesia PTG

BASIC INFORMATION

DEFINITION

Tardive dyskinesia (TD) is a neurological disorder of involuntary movements associated with the long-term use of antipsychotic medication, particularly first-generation antipsychotics. Patients exhibit rapid, repetitive, stereotypic movements that mostly involve the oral, lingual, trunk, and limb areas.

SYNONYMS

Orofacial dyskinesia
Tardive syndrome
TD

ICD-10CM CODE
G24.01 Drug induced subacute dyskinesia
DSM-5 CODE
335.85

EPIDEMIOLOGY & DEMOGRAPHICS

- The disorder is caused by dopamine-blocking antipsychotics (e.g., haloperidol) and antiemetics (e.g., metoclopramide, prochlorperazine, and promethazine).
- With first-generation antipsychotics, at least 20% of patients are affected with TD, and ~5% are expected to develop TD with each yr of antipsychotic treatment.
- The incidence of TD with second-generation antipsychotics is reduced only by about one third. With the increasing use of these medications, TD remains a serious problem.
- Risk increases with the duration of antipsychotic treatment, in female and in elderly patients, in patients with brain damage or dementia, with concurrent anticholinergic use, and in patients with nonschizophrenia diagnoses.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- TD is classically described as a chronic condition of insidious onset, but symptoms are variable over time and may even improve despite continued antipsychotic therapy.
- The condition typically appears with the reduction or withdrawal of the antipsychotic medications.
- TD classically involves stereotypic movements of the mouth and tongue, including lip smacking and puckering, tongue twisting and protrusion, and facial grimacing.
- TD may also involve slow, writhing movements of the trunk or choreoathetoid movements of the fingers and toes.
- The involuntary mouth movements associated with TD may be suppressed by voluntary actions (e.g., putting food in the mouth, talking).
- Variants of TD with similar treatment include tardive dystonia (e.g., torticollis, blepharospasm), tardive myoclonus, tardive akathisia, and tardive tics.

ETIOLOGY

TD is caused by chronic exposure to dopamine receptor antagonists that is thought to result in the upregulation of dopamine receptors in the basal ganglia as well as damage to striatal cholinergic neurons. Dysfunction of striatal GABAergic interneurons has also been implicated. It has been proposed that dopamine receptor hypersensitivity and neurodegenerative changes might cause altered synaptic plasticity of excitatory synapses onto striatal interneurons, resulting in an imbalance between the direct and indirect basal ganglia pathways.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute extrapyramidal symptoms (e.g., short-term withdrawal dyskinesias, Parkinsonism, akathisia)
- Basal ganglia movement disorders (e.g., Huntington chorea, Tourette syndrome, levodopa-induced dyskinesia in Parkinson disease, Wilson disease)
- Autoimmune diseases (Sydenham chorea, multiple sclerosis)
- Other causes of neurologic damage (e.g., lead or mercury toxicity, HIV, neurosyphilis, head injury, neurodegeneration from illicit substances)
- Mannerisms associated with disorganized type or catatonic type schizophrenia or catatonic syndrome associated with mood disorder or medical illness
- Hyperthyroidism-induced choreoathetosis
- Edentulous dyskinesias and improperly fitted dentures
- Rabbit syndrome (a rare variant of extrapyramidal symptoms with rapid vertical orofacial movements without tongue involvement); may respond to anticholinergic agents

WORKUP

TD is a diagnosis of exclusion, with emphasis on a complete neuropsychiatric and medication history and a thorough physical examination.

IMAGING STUDIES

Standard brain imaging is normal in patients with TD.

TREATMENT

ACUTE GENERAL Rx

- Treatment is predicated on prevention: Limit the indications for antipsychotics; use the lowest effective dose; discontinue the drugs, when feasible; and monitor patients frequently. Anticholinergic medications may worsen symptoms.
- Switch to second-generation antipsychotics, if possible.

CHRONIC Rx

- If continued antipsychotic treatment is needed, switching to clozapine or quetiapine is the preferred initial treatment.
- Valbenazine and deutetrabenazine, inhibitors of the vesicular monoamine transporter 2 (VMAT2), are centrally acting synaptic dopamine depleters that are the first FDA-approved treatments for TD and are recommended as first-line treatment options when discontinuation of antipsychotic not indicated. The older version, tetrabenazine, may also improve TD and might be considered.
- Clonazepam and *Ginkgo biloba* probably improve TD.
- Amantadine also has been helpful in some cases.
- For treatment-resistant, disabling TD, deep brain stimulation of internal globus pallidus seems to provide significant symptom reduction without exacerbation of psychiatric symptoms.
- TD is potentially irreversible in nearly two thirds of patients; thus, patients undergoing long-term treatment with dopamine receptor blocking agents require frequent monitoring and aggressive management at the onset of TD symptoms.

REFERRAL

Movement disorder specialist consultation if symptoms are severe

PEARLS & CONSIDERATIONS

- After removal of the causative medication, symptoms of tardive dyskinesia can take mos to resolve or may become permanent (higher risk in elderly, female sex, prolonged use, and higher dose of causative medication).
- First-generation antipsychotics should be resumed to treat TD in the absence of active psychosis only as a last resort for persistent, disabling, and treatment-resistant TD.
- Avoid anticholinergic medications (e.g., benztropine), which may exacerbate TD symptoms.
- Recent evidence suggests increased overall mortality among patients with TD, which highlights the need for referral for more aggressive specialized interventions.

Tarsal Tunnel Syndrome (PTG)

BASIC INFORMATION

DEFINITION

Tarsal tunnel syndrome (TTS) is the most common compressive neuropathy in the foot and ankle. TTS may be secondary to pathologic, structural, or biomechanical factors that cause compression of the tibial nerve and/or its terminal branches (medial calcaneal, medial plantar, lateral plantar nerves) within or distal to the tarsal tunnel (Figs. E1 and E2).

SYNONYMS

Posterior tibial nerve neuralgia
Tibial nerve entrapment neuropathy
TTS

ICD-10CM CODES

G57.50	Tarsal tunnel syndrome, unspecified lower limb
G57.51	Tarsal tunnel syndrome, right lower limb
G57.52	Tarsal tunnel syndrome, left lower limb

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Rare entrapment neuropathy, but the most common entrapment neuropathy in the foot/ankle

PREDOMINANT SEX: The incidence of TTS is higher in females than in males.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Medial heel or ankle pain, distal shooting pain/burning, and generalized foot or ankle pain that is worse after prolonged standing or walking. Pain is usually relieved with rest. Numbness may be present along the plantar foot.
- Localized edema, varicosities, palpable soft tissue masses, biomechanical abnormalities, and signs of trauma.
- Positive Tinel sign: Percussion over the course of the tibial nerve results in distal or proximal radiation of paresthesia (25% to 75% sensitivity and 70% to 90% specificity).
- Compression test: Plantar flexion and eversion of the ankle or digital pressure over the tarsal tunnel reproduces symptoms and is both sensitive and specific.
- Muscle weakness/complete loss of motor function of the plantar foot muscles (late and rare outcome). Atrophy of intrinsic foot musculature if severe nerve injury.
- Heel pain triad: Adult-acquired flatfoot (posterior tibial tendon deficiency), plantar fasciitis, tarsal tunnel syndrome.

ETIOLOGY

- Most common cause: Fracture/dislocation/trauma involving the talus, calcaneus, or medial malleolus (scar tissue, bone, or cartilage fragments, or bony spurs may compress the nerve)
- Intrinsic factors:
  1. Tendinopathy
  2. Osteophytes
  3. Space-occupying lesions/varicosities (most common space-occupying lesion), tumors, ganglion cyst, lipoma, neuroma, perineural fibrosis
  4. Hypertrophic musculature such as abductor hallucis
- Extrinsic factors:
  1. Trauma: Ankle sprain, fracture
  2. Repetitive stress on the tibiotalar joint (jumping, running, etc.)
  3. Constrictive footwear or constrictive cast/bandage
  4. Biomechanical: Tarsal coalition, valgus hindfoot, other hindfoot anomalies

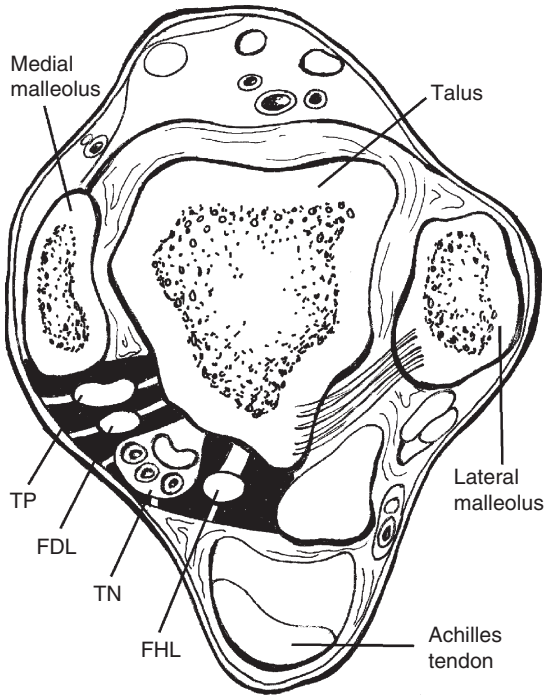

FIG. E1 Anatomy of tarsal tunnel syndrome. Transverse view of ankle. Tendons and neurovascular elements are included in individual fibrous septa that connect periosteum with the deep fascia. *FDL,* Flexor digitorum longus; *FHL,* flexor hallucis longus tendon; *TN,* tibial nerve (single contour), posterior tibial artery, veins; *TP,* tibialis posterior tendon. (From Canoso J: *Rheumatology in primary care,* Philadelphia, 1997, WB Saunders.)

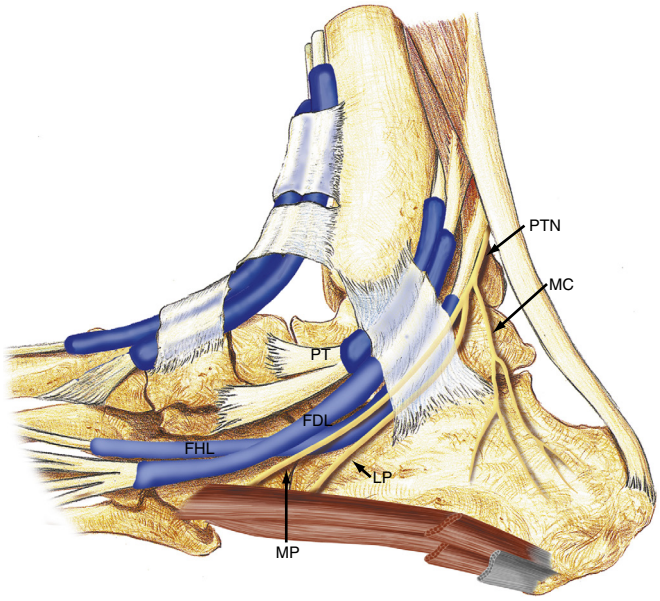

FIG. E2 Normal anatomy of the tarsal tunnel. Drawing of the tarsal tunnel illustrates the flexor retinaculum forming the roof of the tarsal tunnel. The structures contained within the tarsal tunnel include the posterior tibialis tendon *(PT),* flexor digitorum longus tendon *(FDL),* posterior tibial nerve *(PTN)* and its branches, and the flexor hallucis longus *(FHL).* The branches of the PTN are the medial calcaneal nerve *(MC),* the medial plantar nerve *(MP),* and the lateral plantar nerve *(LP).* (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2014, WB Saunders.)

5. Systemic: Diabetes mellitus, hypothyroidism, gout, hyperlipidemia
6. Inflammatory factors/edema: Venous congestion, pregnancy, post-trauma/surgical, rheumatoid arthritis, ankylosing spondylitis

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Plantar fasciitis
- Calcaneal fracture or other osseous trauma
- Ankle sprain/strain or chronic soft tissue injury
- Calcaneal spur
- Tumor
- Posterior tibial tendonitis
- Posterior tibial tendon dysfunction
- Peripheral neuropathy
- Radiculopathy
- Achilles tendonitis or retrocalcaneal bursitis
- Compartment syndrome of deep flexor compartment
- Lumbar spinal stenosis (often bilateral, unlike TTS pain)

WORKUP

- Detailed history and physical
- Biomechanical evaluation and examination

DIAGNOSTIC STUDIES

- X-rays: Can help rule out trauma, bone tumor, structural deformity.
- MRI (Fig. E3): Can identify edema, fibrosis, tumors, varicosities, ganglionic cysts, tenosynovitis, muscle hypertrophy, and evidence of trauma. MRI may enhance surgical planning by revealing the extent of decompression required.
- Electromyography/nerve conduction studies: Prolonged tibial motor distal latencies and slowing of conduction velocities across the flexor retinaculum when studying medial and lateral plantar nerves. Comparison studies with unaffected extremity may be helpful. The sensory nerve conduction velocity is arguably the most accurate study, with a sensitivity of about 90%.
- Ultrasound: Can help identify, aspirate, or perform a biopsy on space-occupying lesions.
- Diagnostic local injections: Relief following an injection of an anesthetic around the affected nerve can help confirm diagnosis.

Rx TREATMENT

CONSERVATIVE

- Rest, ice, elevation, immobilization with night splint or removable boot walker
- Address shoe gear problems
- NSAIDs, antidepressants, antiseizure medications, vitamin B_6
- Topical lidocaine or fentanyl patches, capsaicin, transdermal clonidine, compound mixtures
- Custom orthotics: Heel lifts, medial arch support, medial heel wedge, heel seat
- Bracing/taping: Ankle brace/stirrup brace for ankle instability, plantar arch taping
- Physical therapy: Iontophoresis, interferential current therapy, stretching, strengthening
- Local steroid injections: Anesthetics to reduce pain and/or corticosteroids to help decrease inflammation
- Support hose to control edema
- All of these are usually ineffective due to the structural nature of problem

SURGICAL

- Indicated in patients who have failed conservative treatment for 3 to 6 mo and in those with reproducible physical exam findings, EMG findings, and correctible surgical abnormality
- Nerve decompression: Open or endoscopic release of retinaculum, mass excision, etc. (reported success rates range from 75% to 91%, and recurrence rates of 17% have been reported)
- Correction of associated deformity/adjacent pathologic structure, if present
- Patients with symptoms for <1 yr often have significantly better outcomes after surgery than patients with a longer history
- Postoperative instructions: Elevation, partial weight bearing with assistance of crutches, sutures remain in place for 10 to 12 days
- Complications: New neurological deficits, complex regional pain syndrome, impaired wound healing, infection, keloid formation, swelling, worsening of symptoms

DISPOSITION

TTS can lead to pain and dysesthesias in the calf and sole of the foot as well as dysfunction of the foot flexors and intrinsic muscles. Patients with TTS may experience lifelong chronic pain with unknown etiology or a limited course once the causative factor is resolved (mechanical, healed ankle sprain, soft tissue mass resection, etc.).

REFERRAL

- Foot and ankle surgery referral should be initiated early
- Physical therapy or sports medicine
- Pain management

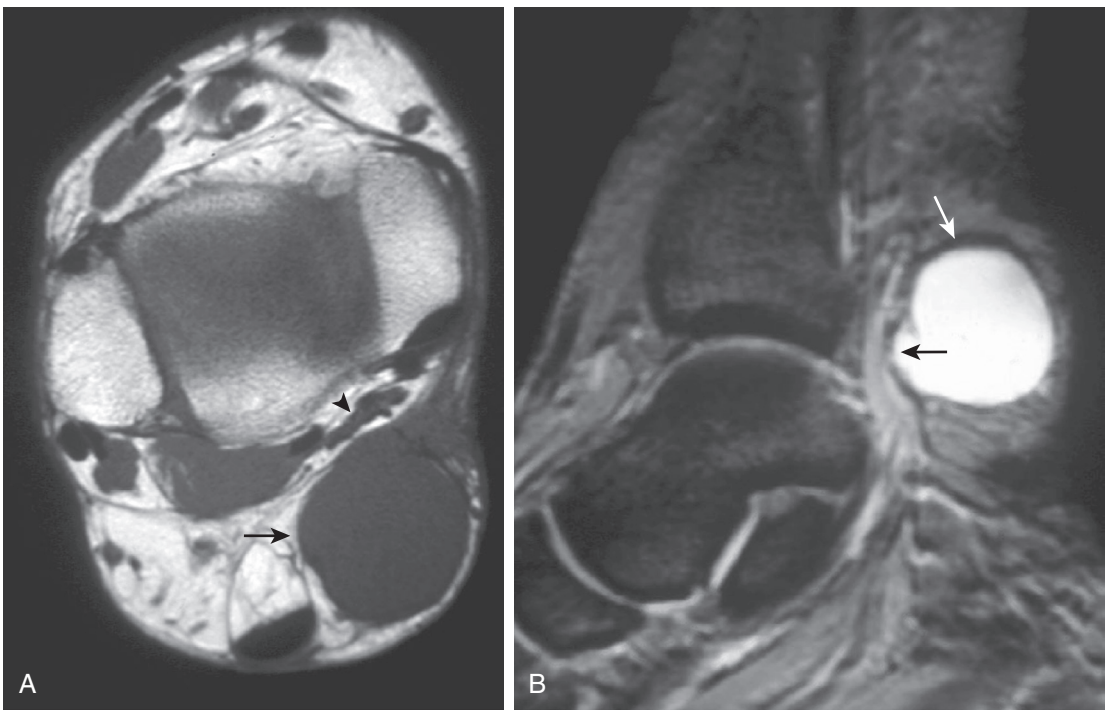

FIG. E3 Tarsal tunnel syndrome. Axial T1-weighted **(A)** and sagittal gradient-recalled echo **(B)** images demonstrate a large ganglion cyst *(arrow)* producing compression of the posterior tibial nerve (*black arrow,* **B**) at the level of the tarsal tunnel. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2014, WB Saunders.)

PEARLS & CONSIDERATIONS

TTS can be mistaken for plantar fasciitis or Achilles tendonitis. Differentiation between these entities is important for proper treatment (refer to "Plantar Fasciitis").

RELATED CONTENT

Tarsal Tunnel Syndrome (Patient Information)

AUTHORS: **Christopher McDonald, MD,** and **Brad Blankenhorn, MD**

BASIC INFORMATION

DEFINITION

Temporomandibular joint (TMJ) syndrome refers to a group of disorders leading to symptoms of the TMJ. Box 1 describes a classification of temporomandibular joint disorder (TMD), which also can be classified as intraarticular (within the joint) or extraarticular (involving the surrounding musculature). The TMJ is a diarthrotic joint, meaning neither joint can move independently of the other because each is hinged at both ends. The joint is a true synovial joint capable of two actions of movement: translational and rotational. The articulating surfaces are the glenoid fossa of the temporal bone and the condylar process of the mandible, with the articular disk interposed between the two.

SYNONYMS

Temporomandibular dysfunction
Painful temporomandibular joint
TMJ
Temporomandibular disorders (TMD)

ICD-10CM CODE
N26.60 Temporomandibular joint disorder, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- 15% to 25% of the population have symptoms of TMJ disorders at some point in their lives.
- Females are affected more often than males (up to 4:1 ratio).
- Occurs between the second and fourth decades of life.
- Usually unilateral, affecting either side with equal frequency.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms may appear or be worse during stressful life events.
  1. Often unilateral pain in the muscles of mastication, usually described as a "dull" ache
  2. Otalgia
  3. Odontalgia
  4. Headaches (frontal, temporal, retroorbital)
  5. Tinnitus
  6. Dizziness
  7. Clicking or popping sounds with movement of the TMJ
  8. Joint locking
- Fig. E1 illustrates the clinical examination of the temporomandibular joint, range of mandibular motion, and muscle palpation.
- Physical exam findings:
  1. Tender to palpation over TMJ in external auditory meatus or preauricular region anterior to tragus
  2. Limited jaw opening or trismus
  3. Clicking or popping of TMJs with joint mobility
  4. Lateral deviation of mandible
  5. TMJ crepitus

ETIOLOGY

- Myofascial pain-dysfunction syndrome: The most common cause of TMJ syndrome and results from teeth grinding and clenching the jaw (bruxism)
- Internal TMJ derangement: Abnormal connection of the articular disk to the mandibular condyle as a result of disk displacement or chronic dislocations
- Degenerative joint disease
- Rheumatoid arthritis
- Gouty arthritis
- Pseudogout
- Ankylosing spondylitis
- Trauma (i.e., fractures)
- Congenital defects (i.e., aplasia, hypoplasia)
- Prior surgery (orthodontic, intraarticular steroid injection)
- Tumors

DIAGNOSIS

Can be made based on history and physical examination in most cases.

DIFFERENTIAL DIAGNOSIS

Includes the list provided earlier. Myofascial pain-dysfunction syndrome, internal TMJ derangement, and degenerative joint disease represent >90% of all causes of TMJ syndrome. Others not mentioned include dental problems such as dental caries, loss of posterior teeth support, and Eagle syndrome (stylohyoid syndrome, carotidynia, and trigeminal neuralgia). Alternative diagnoses such as otitis, mastoiditis, salivary gland disorders, migraine headache, sinusitis, postherpetic neuralgia, trigeminal neuralgia, glossopharyngeal neuralgia, and giant cell arteritis should always be excluded.

WORKUP

The diagnosis is based largely on history and physical examination findings. Radiographic imaging evaluation is used to exclude anatomic or systemic causes of disease when conservative management has failed.

LABORATORY TESTS

Laboratory examination is often not needed but may be helpful in ruling out certain conditions. CBC if infection is suspected. Rheumatoid factor if rheumatoid arthritis is suspected.

IMAGING STUDIES

- Plain radiographs: The most common views are the panoramic, transorbital, and transpharyngeal in both opened and closed positions.
- CT scan is highly accurate in diagnosing osseous derangements of the TMJ.
- MRI is the procedure of choice and has replaced arthrography in cases of disabling pain or if locking occurs. It is used to determine disk position and morphology along with degenerative bony changes.
- Arthrography is helpful in looking for meniscus involvement but is seldom performed anymore, as it is more invasive and less accurate than MRI for TMJ imaging.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Soft diet to rest the muscles of mastication
- Heat 15 to 20 min 4 to 6 times per day
- Massage of the masseter and temporalis muscles
- Formed splints or bite appliances to reduce compression of retrodiscal tissue (Fig. 2)
- Range-of-motion exercises
- Cognitive-behavioral therapy and biofeedback have been shown to reduce pain.
- Acupuncture

ACUTE GENERAL Rx

- NSAIDs: Ibuprofen 800 PO mg tid prn or naproxen 500 mg PO bid prn, titrated to relieve symptoms
- Muscle relaxants or benzodiazepines at bedtime: Diazepam 2.5 to 5 mg PO tid prn or amitriptyline 5 to 100 mg PO qd prn

BOX 1 Classification of Temporomandibular Joint Disorder

Myofascial pain disorder and dysfunction
Most common; primarily of muscular origin
Characterized by myogenous pain and limited mandibular function
May be associated with parafunctional habits, stress, anxiety, depression, or trauma

Temporomandibular joint internal displacement (disk displacement)
Reducing or nonreducing (closed lock) with joint sounds and deviation with opening
Most common is anteromedial displacement of the disk
Results in a mechanical interference, leading to moderate to severe restriction in range of motion

Systemic diseases (arthritides, e.g., rheumatoid arthritis, psoriatic arthritis, osteoarthritis)
Affect the joint through inflammation or degenerative processes
May result in condylar remodeling and degenerative joint disease
Also may be related to infectious processes triggering joint inflammation

Congenital and developmental diseases (including trauma and neoplasms)
Hemifacial microsomia or condylar hyperplasia
Idiopathic condylar resorption
Ankylosis
Tumors (e.g., osteochondroma)

From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

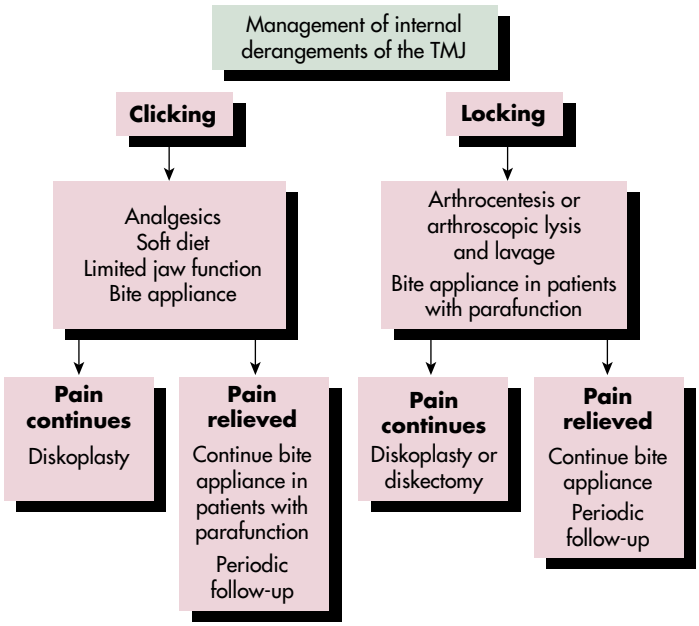

FIG. 2 Management of internal derangements of the temporomandibular joint *(TMJ)*. Patients with painful clicking or locking are treated medically initially, whereas those with locking require surgical intervention. (From Firestein GS et al: *Kelley's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.)

- In degenerative joint disease of the TMJ, intraarticular steroid injection can be tried
- Botulism toxin injections into the masticatory muscles
- Arthrocentesis with joint lavage and lysis of adhesions (Fig. E3)
- In patients with pain and clicking in the TMJ that is unresponsive to nonsurgical treatment, the disc should be repositioned arthroscopically or by open surgery (discoplasty) (see "Chronic Rx")

CHRONIC Rx

- Most of the above treatments are used for myofascial pain-dysfunction syndrome; however, they can be applied to other causes of TMJ syndrome. Surgery is usually a measure of last resort in patients who do not respond to nonpharmacologic and acute general treatment. Absolute indications for surgical therapy include neoplasms, growth abnormalities, and joint ankylosis.
- Surgical procedures include:
  1. Meniscoplasty
  2. Meniscectomy
  3. Subcondylar osteotomy
  4. TMJ reconstruction

DISPOSITION

The course depends on the underlying etiology; however, less than 5% of adults with temporomandibular symptoms develop chronic symptoms.

REFERRAL

All patients with TMJ syndrome refractory to conservative nonpharmacologic and acute therapy should be referred to a periodontist, oral maxillofacial surgeon, or ear-nose-throat surgeon.

PEARLS & CONSIDERATIONS

Patients with rheumatoid arthritis involving the TMJ usually have bilateral involvement.

COMMENTS

Frequently, emotional stress initiates the myofascial pain-dysfunction, which accounts for 85% of all cases of TMJ syndrome.

BASIC INFORMATION

DEFINITION

Tension-type headache (TTH) is a highly prevalent primary headache disorder not associated with nausea or vomiting. Although previously thought to be caused by psychological factors and muscle contraction, current thinking implicates neurobiological mechanisms.

ICD-10CM CODES

G44.201	Tension-type headache, unspecified, intractable
G44.209	Tension-type headache, unspecified, not intractable

EPIDEMIOLOGY & DEMOGRAPHICS

Most common type of headache, representing 70% of all headaches presenting to primary care physicians. Women are affected more often than men.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Headaches have an insidious progression, ranging from infrequent (<1 day per mo) to chronic. Although considered a "featureless" headache disorder, either photophobia or phonophobia may still be present. Concurrent problems, such as anxiety, depression, and analgesic overuse, may aggravate the headaches. Patients may have pericranial tenderness to palpation on exam. The rest of the examination should be normal.

PATHOPHYSIOLOGY

- TTH is no longer thought to be due to either a psychological problem or abnormal muscle contraction. Similar to migraine, TTH is likely a heterogeneous disorder with several possible pathophysiologic mechanisms.
- In episodic TTH, peripheral mechanisms may predominate, whereas in chronic TTH, central mechanisms are involved.

DIAGNOSIS

The International Headache Society criteria for tension-type headache are as follows:

- At least 10 headaches
- Lasting from 30 min to 7 days
- Having at least two of the following features:
  1. Bilateral
  2. Pressure or tightening (non-pulsating) quality
  3. Mild or moderate intensity
  4. Not aggravated by routine physical activity such as walking or climbing stairs
- Both of the following:
  1. No nausea or vomiting
  2. No more than one of either photophobia or phonophobia
- Not better accounted for by another diagnosis

DIFFERENTIAL DIAGNOSIS

- Migraine (would expect associated symptoms [i.e., nausea]; see topic "Migraine Headache")
- Cervical spine disease
- Intracranial mass (may present with focal neurologic signs, seizures, or headache awakening patient from sleep)
- Idiopathic intracranial hypertension (found more often in obese women of childbearing age)
- Medication overuse headache
- Secondary headache (e.g., obstructive sleep apnea, temporomandibular joint syndrome, hypo- or hyperthyroidism, drug side effects)
- Section II describes the differential diagnosis of headaches

WORKUP

- Routine testing is not needed; the diagnosis may be established clinically.
- Thorough history to identify any red flag features (see topic "Migraine Headache," SSNOOP5 mnemonic in Differential Diagnosis) and physical examination (looking for papilledema) for all patients being evaluated for headache.
- Neuroimaging, preferably with contrast-enhanced MRI, should be performed only when red flag features are identified by history or unexplained neurologic findings are present on examination.
- Erythrocyte sedimentation rate and C-reactive protein in patients 50 yr of age and older to screen for giant cell arteritis.

TREATMENT

Current evidence supports synergistic benefits of combined nonpharmacologic and pharmacologic interventions. Nonpharmacologic therapy may include behavioral sleep modification, acupuncture, cognitive-behavioral therapy, relaxation training, and biofeedback.

ACUTE Rx

- Simple analgesics (i.e., NSAID, acetaminophen).
- Combination analgesics containing caffeine may be used as second-line treatment, although use on more than 10 days per mo may lead to medication overuse headache.
- As with migraine headaches, narcotic- and barbiturate-containing analgesics should be avoided in tension-type headaches.

PREVENTIVE Rx

- Tricyclic antidepressants (e.g., amitriptyline 10 to 50 mg qhs) (first choice)
- Other options: Mirtazapine, venlafaxine, and tizanidine

DISPOSITION

The headache prognosis is generally favorable. Some patients will not respond to treatment.

REFERRAL

If red flags are present on history or exam or if the patient is not improving with treatment

PEARLS & CONSIDERATIONS

It is imperative to avoid overuse of caffeine as well as narcotic-, and barbiturate-containing medications because of the risk of rebound headaches.

BASIC INFORMATION

DEFINITION

Testicular cancers are primary germ cell cancers originating in the testis. They are the most common cancers in men between the ages of 15 and 44 yr, and incidence has been increasing gradually since 1975.

SYNONYMS

Testis tumor
Testicular neoplasms

ICD-10CM CODES

C62.00	Malignant neoplasm of unspecified undescended testis
C62.01	Malignant neoplasm of undescended right testis
C62.02	Malignant neoplasm of undescended left testis
C62.10	Malignant neoplasm of unspecified descended testis
C62.11	Malignant neoplasm of descended right testis
C62.12	Malignant neoplasm of descended left testis
D40.10	Neoplasm of uncertain behavior of unspecified testis
D40.11	Neoplasm of uncertain behavior of right testis
D40.12	Neoplasm of uncertain behavior of left testis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: There were an estimated 9560 new cases and 410 deaths associated with testicular cancer in the U.S. in 2019. The incidence is 5.4 cases per 100,000 men annually. White men have the highest incidence, whereas black men have the lowest incidence.

PREVALENCE: It accounts for 1% to 2% of all cancers in males.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Testicular cancer typically presents as a painless mass in the testis. Any mass within the testicle should be considered cancer until proven otherwise. It may be found by the patient, who brings it to the attention of a physician, or it may be found by a physician on a routine examination.
- Symptoms other than scrotal or testicular swelling are typically absent unless the cancer has metastasized (10% of patients at diagnosis). Occasionally a patient may report scrotal fullness or heaviness. About 10% of patients present with acute pain. Back pain secondary to enlarged retroperitoneal lymph nodes can occur. Gynecomastia from tumors that secrete beta-human chorionic gonadotropin (hCG) is found in 5% of men with testicular cancer.
- Testicular palpation should be performed with two hands. Transillumination may distinguish a solid mass (e.g., cancer) and a fluid-filled lesion (e.g., hydrocele or spermatocele). The mass is nontender; indeed, it is less sensitive than a normal testicle.

ETIOLOGY, CLASSIFICATION, & PATHOLOGY

- Cryptorchidism (undescended testes) is a major risk factor even if corrected by orchiopexy; however, treatment of undescended testis before puberty decreases the risk of testicular cancer from fivefold to twofold.
- Family history is an important risk factor (risk is four to eight times as high in a brother of a person with testicular cancer and four to six times higher in sons of a father with testicular cancer)
- Other risk factors include genetic disorders (Down syndrome, testicular dysgenesis syndrome), Klinefelter syndrome, infertility, tobacco use, and white race (risk is highest among whites and lowest among blacks).
- Classification: Testicular cancers can be classified as pure seminomas or nonseminomatous germ cell tumors (embryonal carcinoma, choriocarcinoma, yolk sac carcinoma, teratoma, or mixed germ cell tumors).
- Germ-cell tumors appear to develop as a result of a tumorigenic event in utero that leads to a precursor lesion classified as intratubular germ-cell neoplasia. Approximately 90% of germ-cell tumors are associated with adjacent intratubular germ-cell neoplasia, which carries a 50% risk of testicular cancer within 5 yr. Table 1 summarizes germ cell tumors and serum markers.
- A genetic locus that confers a predisposition to testicular cancer is at 12q21, the location of the genes encoding the proteins involved in KITLG–KIT signaling. The development of intratubular germ-cell neoplasia may involve aberrantly activated KITLG–KIT in utero, which induces arrest of embryonic germ cells at the gonocyte stage; subsequently, overexpression of embryonic transcription factors leads to suppression of apoptosis, increased proliferation, and accumulation of mutations in gonocytes.
- The incidence of various subtypes of testicular cancers is as below:

Cell Type	Frequency (%)
Seminoma	42
Embryonal cell carcinoma	26
Teratocarcinoma	26
Teratoma	5
Choriocarcinoma	1

- Other rare types:
  1. Yolk sac carcinoma
  2. Mixed germ cell tumors
  3. Carcinoid tumor
  4. Sertoli cell tumors
  5. Leydig cell tumors
  6. Lymphoma
  7. Metastatic cancer to the testes

STAGING

- TNM staging system for testicular cancer is described in Table 2 and Table 3.
- The clinical stages consist of stage I, with tumor confined to the testis; stage II, with positive regional lymph nodes; and stage III, with metastases. Fig. 1 shows the clinical staging of testicular cancer.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Spermatocele
- Varicocele
- Hydrocele
- Epididymitis/orchitis
- Epidermoid cyst of the testicle
- Epididymis tumors
- Inguinal hernia
- Hematocele or testicular rupture
- Torsion of testicular appendage
- Skin cancer

WORKUP

Physical examination, laboratory tests, and imaging studies (Fig. 2). A radical inguinal orchiectomy is diagnostic and therapeutic. Immunohistochemical analysis is used to determine the histologic composition of the tumor. Staging involves CT of chest, abdomen, and pelvis and measurement of beta subunit

TABLE 1 Germ Cell Tumors and Serum Markers

Histology	Marker Negative (%)	Elevated hCG Alone (%)	Elevated AFP Alone (%)
Seminoma	90	10 (usually <100 IU/ml)	0 (if +, by definition, NSGCT)
All NSGCTs	15	50-60	40
Embryonal		0	10-40
Yolk sac tumors		Rare	80-90 (alone or with elevated hCG)
Choriocarcinoma (or syncytiotrophoblast elements)		>90 (level can be very high)	0

AFP, α-Fetoprotein; *hCG,* human chorionic gonadotropin; *NSGCT,* nonseminoma germ cell tumor.
From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE 2 TNM Staging for Testicular Cancer (*AJCC 8th Edition Staging Cancer Manual*)

pT Stage	Primary Tumor
pT_X	Primary tumor cannot be assessed
pT_0	No evidence of primary tumor
pT_{is}	Germ cell neoplasia *in situ*
pT_1	Tumor limited to testis (including rete testis invasion) without lymphovascular invasion pT_{1a}: Tumor smaller than 3 cm in size (seminoma only) pT_{1b}: Tumor 3 cm or larger in size (seminoma only)
pT_2	Tumor limited to testis (including rete testis invasion) with lymphovascular invasion OR tumor invading hilar soft tissue or epididymis or penetrating visceral mesothelial layer covering the external surface of tunica albuginea with or without lymphovascular invasion
pT_3	Tumor directly invades spermatic cord soft tissue with or without lymphovascular invasion
pT_4	Tumor invades scrotum with or without lymphovascular invasion
N Stage	**Regional Lymph Nodes**
N_x	Regional lymph nodes cannot be assessed
N_0	No regional lymph node metastasis
N_1	Metastasis with a lymph node mass 2 cm or smaller in greatest dimension OR multiple lymph nodes, none larger than 2 cm in greatest dimension
N_2	Metastasis with a lymph node mass larger than 2 cm but not larger than 5 cm in greatest dimension OR multiple lymph nodes, any one mass larger than 2 cm but not larger than 5 cm in greatest dimension
N_3	Metastasis with a lymph node mass larger than 5 cm in greatest dimension
M Stage	**Distant Metastasis**
M_0	No distant metastasis
M_1	Distant metastasis present M_{1a}: Nonretroperitoneal nodal or pulmonary metastases M_{1b}: Nonpulmonary visceral metastases
S	**Serum Tumor Markers**
S_x	Not available
S_0	Markers within normal levels
S_1	LDH <1.5 × N *and* hCG (mIU/ml) <5000 *and* AFP (ng/ml) <1000
S_2	LDH 1.5-10 × N *or* hCG (mIU/ml) 5000–50,000 *or* AFP (ng/ml) 1000-10,000
S_3	LDH >10 × N *or* hCG (mIU/ml) >50,000 *or* AFP (ng/ml) >10,000

AJCC, American Joint Committee on Cancer; *TNM,* tumor, necrosis, metastases.

TABLE 3 AJCC Prognostic Stage Groupings

Stage	T	N	M	S
0	pT_{is}	N_0	M_0	S_0
I	pT_{1-4}	N_0	M_0	S_X

	Any T	Any N	M_{1b}	Any S

AJCC, American Joint Committee on Cancer.

of human chorionic gonadotropins (β-hCG), alpha-fetoprotein (AFP), and lactate dehydrogenase (LDH).

LABORATORY TESTS

- Serum β-hCG is elevated in approximately 20% of patients with pure seminomas.
- Serum AFP is elevated in nonseminoma tumors, never elevated in patients with pure seminomas.

One or both of these tumor markers will be elevated in 70% of cases of testicular cancer.

- Serum lactate LDH level is elevated with rapid turnover of malignant cells.
- Testicular biopsy is contraindicated.

IMAGING STUDIES

- Testicular ultrasound
- CT scan of chest, pelvis, and abdomen
- MRI of the brain in patients with neurologic symptoms
- PET scan is not recommended (frequent false positives)

Rx TREATMENT

- Box E1 summarizes a treatment algorithm for testicular cancer.
- Seminoma:
  1. Stage I: Most patients with clinical stage 1 are cured with orchiectomy. Radical inguinal orchiectomy plus one cycle of single-agent carboplatin chemotherapy or radiation therapy (RT) to the paraaortic lymph nodes is a standard treatment option. However, it has been replaced in many instances with active surveillance postorchiectomy. More relapses are associated with surveillance (20% vs. 4% with radiotherapy or chemotherapy), but long-term survival approaches 100% irrespective of initial option chosen.[1]
  2. Stage II_A or II_B: RT or cisplatin-based chemotherapy (e.g., bleomycin, etoposide, and cisplatin [BEP]).
- Nonseminoma:
  1. Stage I_A: Radical orchiectomy plus nerve-sparing retroperitoneal lymph node dissection (RPLND)
  2. Stage I_B: Same as stage I_A plus two cycles of chemotherapy (bleomycin, etoposide, and cisplatin [BEP])
  3. Stages II-III: Multiagent cisplatin-based chemotherapy regimens for three or four cycles depending on risk stratification (low/intermediate or high). RPLND is offered for residual lymph nodal disease after chemotherapy
- Relapsed disease:
  1. Salvage chemotherapy using multiagent regimens is offered. Active drugs include ifosfamide, paclitaxel, cisplatin, vinblastine, and cisplatin.
  2. Chemotherapy-sensitive patients can be successfully treated with high-dose chemotherapy followed by autologous stem cell transplantation (ASCT).
- Posttreatment surveillance for testicular cancer survivors (annually):
  1. Fertility assessment
  2. Physical examination and skin examination (increased risk of dysplastic nevi)
  3. Testicular examination (3% to 4% risk of second testicular cancer)
  4. Serum tumor markers (hCG, AFP)
  5. Abdominal and pelvic CT every 3 to 4 mo for 2 yr, every 6 to 12 mo in third and fourth yr, and annually thereafter

[1]Hanna NH, Einhorn LH: Testicular cancer, discoveries and updates, *N Engl J Med* 371:2005-2016, 2014.

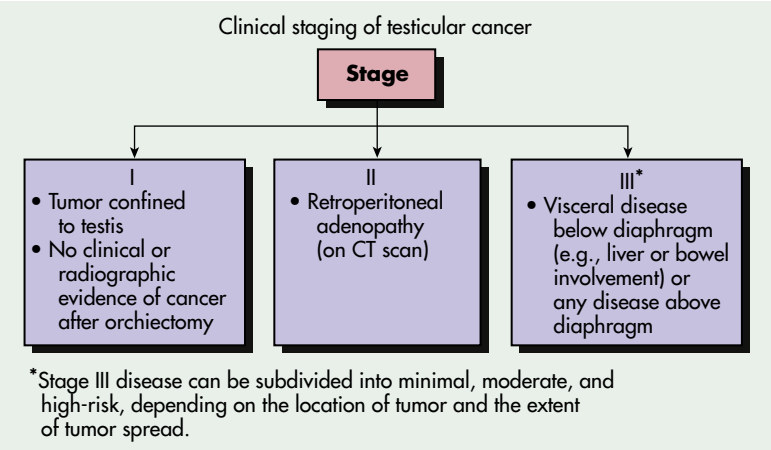

FIG. 1 Clinical staging of testicular cancer. The American Joint Committee on Cancer TNM staging system is less commonly used, because it is based upon histologic evaluation of the orchidectomy specimen and retroperitoneal periaortic lymph node dissection. Because the latter may not be performed in every patient, the clinical staging system is generally more practical. (From Skarin AT: *Atlas of diagnostic oncology,* ed 4, St Louis, 2010, Mosby.)

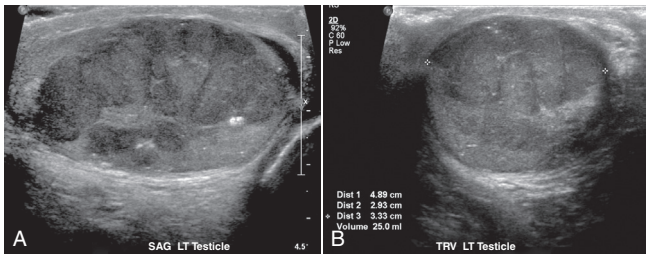

FIG. 2 Seminoma in an 18-year-old patient with painless left scrotal mass. A and **B,** Sagittal and transverse sonograms of the left testis demonstrate a testicular volume of 25 ml, with a lobulated, heterogeneous, relatively hypoechoic mass occupying most of the testis with a thin rim of normal testis and a few tiny clusters of calcification, as well as multiple, tiny, brightly echoic speckles both inside and outside the mass. The tiny speckles represent microlithiasis. (From Rumack CM et al: *Diagnostic ultrasound,* ed 4, Philadelphia, 2011, Elsevier.)

DISPOSITION

- The overall cure for testicular cancer is >95% (80% for metastatic disease). Patients with pure seminomas have a better prognosis. Prognosis can be determined by criteria established by the International Germ Cell Consensus Criteria (Table E4). Because treatment produces favorable outcomes even in advanced stages, the U.S. Preventive Services Task Force recommends against screening asymptomatic men for testicular cancer.
- There is an increased risk for metabolic syndrome (insulin resistance, hypertension, dyslipidemia, abdominal obesity) after radiation or chemotherapy. Additionally, effects on long-term reproductive health, lower fertility, hearing impairment, neuropathy, and Raynaud phenomenon are long-term toxicities seen with chemotherapy use.
- Therapeutic radiation and chemotherapy are risk factors for cancers of thyroid, lymphoma, kidney, pancreas, stomach, and leukemia. There is also an increased risk for metabolic syndrome (insulin resistance, hypertension, dyslipidemia, abdominal obesity) after radiation or chemotherapy.

Testicular Cancer (Patient Information)

AUTHOR: **Bharti Rathore, MD**

BOX E1 Treatment Algorithm

1. Suspicious testicular mass:
   - History and physical examination (H&P)
   - α-fetoprotein (AFP)
   - β-human chorionic gonadotropin (β-hCG)
   - Lactate dehydrogenase (LDH)
   - Chemistry profile
   - Testicular ultrasonography
2. Radical inguinal orchiectomy:
   - Consider inguinal biopsy of contralateral testis if ultrasound findings raise suspicion for intratesticular abnormalities, cryptorchid testis, or marked atrophy.
3. If orchiectomy shows pure seminoma:
   - Abdominal and pelvic computed tomography (CT)
   - Chest radiography
   - Consider chest CT if positive abdominal CT or abnormal chest radiograph
   - Discuss sperm banking, if clinically indicated

   3a. For stage I_A/I_B pure seminoma, consider the following:
      - Surveillance
      - Single-agent carboplatin (area under the curve [AUC] 7 × 1-2 cycles)
      - Radiation therapy

   3b. For stage II_A pure seminoma, consider the following:
      - Radiation therapy
      - Chemotherapy (BEP × 3 cycles of EP × 4 cycles)

   3c. For stage II_B pure seminoma, consider the following:
      - Chemotherapy (BEP × 3 cycles of EP × 4 cycles)
      - Radiation therapy (only for nonbulky, <3 cm cases)

   3d. For stage II_C/III pure seminoma, consider the following:
      - Chemotherapy
      - Good-risk disease: BEP × 3 cycles of EP × 4 cycles
      - Intermediate-risk disease: BEP × 4 cycles or VIP × 4 cycles

   3e. Postchemotherapy management for pure seminoma:
      - Residual mass >3 cm: PET-CT, resection of disease if positive, second-line chemotherapy if viable seminoma detected
      - Residual mass <3 cm or no residual mass: Surveillance
4. If orchiectomy shows nonseminoma or any mixed histologic types:
   - Chest, abdominal, pelvic CT
   - Repeat tumor marker testing (AFP, β-hCG, LDH)
   - Brain magnetic resonance imaging (MRI) if clinically indicated
   - Discuss sperm banking, if clinically indicated

   4a. For stage I_A/I_B pure seminoma, consider the following:
      - Surveillance
      - Adjuvant chemotherapy (BEP × 1-2 cycles)
      - Nerve-sparing RPLND

   4b. For stage II_A/II_B without elevated markers, consider the following:
      - Primary nerve-sparing RPLND (use cautiously for II_B)
      - If pathologic N_1, then consider surveillance vs adjuvant BEP × 2 cycles or EP × 2 cycles
      - If pathologic N_2, then consider adjuvant BEP × 2 cycles or EP × 2 cycles
      - If pathologic N_3, then consider adjuvant BEP × 3 cycles or EP × 4 cycles
      - Primary chemotherapy (BEP × 3 cycles or EP × 4 cycles)

   4c. For stage I_s, II_A with elevated markers, II_B with elevated markers, II_C, or III, consider the following:
      - Chemotherapy (BEP × 3 or EP × 4 if good risk; if intermediate or poor risk, then BEP × 4 or VIP × 4)

   4d. Postchemotherapy management for nonseminoma and mixed histologic types:
      - Residual mass >1 cm: Resection of disease if possible (RPLND or lung resection)
      - Consider adjuvant chemotherapy (BEP × 2 cycles or EP × 2 cycles) if residual viable germ cell tumor disease present at time of resection
5. Recurrence after initial therapy:
   - Referral to specialized center for evaluation
   - Consider surgical salvage if late relapse (>2 yr)
   - Consider conventional-dose chemotherapy (TIP × 4 or VeIP × 4) vs high-dose chemotherapy with autologous transplant

BASIC INFORMATION

DEFINITION

Testicular torsion is a twisting of the spermatic cord leading to cessation of testicular blood flow, ischemia, and infarction if left untreated.

SYNONYM

Spermatic cord torsion

ICD-10CM CODE
N44.03 Torsion of testis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Affects 1 in 4000 males <25 yr
PREDOMINANT AGE: Two thirds of all cases occur between the ages of 12 and 18 yr but may occur at any age, including antenatally.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typical sequence is sudden onset of hemiscrotal pain, then swelling, nausea, and vomiting without fever or urinary symptoms.
- Physical examination may reveal a tender firm testis, high-riding testis, horizontal lie of testis, absent cremasteric reflex, and no pain with elevation of testis. Absence of the cremasteric reflex (stroking or pinching the medial thigh causing contraction of cremaster muscle and elevation of testis) is the most sensitive physical finding.
- Painless testicular swelling occurs in 10%.
- One out of three patients reports previous episodes of spontaneously remitting scrotal pain.
- In the neonate, testicular torsion should be presumed in patients with a painless, discolored hemiscrotal swelling.
- In rare cases, torsion may involve an undescended testicle. In such situations an empty hemiscrotum is palpated with a tender lump in the inguinal area.

ETIOLOGY

- There are three types of testicular torsion: extravaginal, caused by nonadherence of the tunica vaginalis to the dartos layer; intravaginal torsion, caused by malrotation of the spermatic cord with the tunica vaginalis; and torsion of the testis below the epididymis (Fig. E1). Intravaginal torsion accounts for 90% of cases.
- Torsion usually occurs in the absence of any precipitating events. Trauma accounts for <10% of cases.

DIAGNOSIS

Diagnosis made mainly by clinical suspicion (Table E1). Color Doppler ultrasound evaluation or a nuclear testicular scan (Figs. E2 and E3) may help with diagnosis. Ultrasonography shows absent or decreased blood flow; scintigraphy reveals decreased perfusion on symptomatic side.

DIFFERENTIAL DIAGNOSIS

- Torsion of the testicular appendages (appendix testis)
- Testicular tumor
- Epididymitis
- Incarcerated inguinoscrotal hernia
- Orchitis
- Spermatocele
- Hydrocele, varicocele

WORKUP

The diagnosis is usually based on history and physical examination.

IMAGING STUDIES

- Doppler ultrasonic stethoscope (Doppler flowmetry) (Fig. E3)
- Radionuclide scrotal scanning (technetium-99m): Cold testicle (Fig. E2)

TREATMENT

Surgical derotation of the spermatic cord followed by bilateral testicular fixation with nonabsorbable sutures. If affected testis is nonviable, orchiectomy of affected testis and orchiopexy of contralateral side are performed. Attempts at manual detorsion should not delay surgical consultation.

PROGNOSIS

- The degree of ischemia depends on the duration of torsion and the degree of rotation of the spermatic cord.
- There is an 80% testicular salvage rate if detorsion occurs within 12 hr of onset.
- After 24 hr, irreversible testicular infarction is expected.
- Because contralateral testes can be affected (immunologic process), if treatment delayed and blood flow does not return after detorsion, some recommend orchiectomy of the infarcted testicle.

PEARLS & CONSIDERATIONS

- Manual detorsion by external rotation of the testis toward the thigh can be attempted for adolescent intravaginal torsion if an operating facility is not readily available.
- Extravaginal torsion is diagnosed in the newborn. Intravaginal torsion can occur at any age but is usually diagnosed in males ages 12 to 18 yr.

TABLE E1 Differentiation of Testicular Torsion, Epididymitis, and Appendage Torsion

	Testicular Torsion	Epididymitis*	Appendage Torsion
Historical Features			
Age	Peak incidence in neonatal and adolescent groups but may occur at any age	Primarily adolescents and adults but may occur at any age	Typically prepubertal boys
Risk factors	Undescended testicle (neonate), rapid increase in testicular size (adolescent), failure of previous orchiopexy	Sexual activity or promiscuity, GU anomalies, GU instrumentation	Presence of appendages
Pain onset	Sudden	Gradual	Gradual or sudden
Previous episodes of similar pain	Possible (spontaneous detorsion)	Unlikely	Occasional
History of trauma	Possible	Possible	Possible
Nausea, vomiting	More likely	Less likely	Less likely
Dysuria	Less likely	More likely	Less likely
Physical Findings			
Fever	Less likely	More likely, particularly with advanced disease (epididymo-orchitis)	Less likely
Location of swelling and tenderness	Testicle, progressing to diffuse hemiscrotal involvement	Epididymis, progressing to diffuse hemiscrotal involvement	Localized to head of affected testicle or epididymis
Cremasteric reflex	Testicular torsion less likely if present	May be present or absent	May be present or absent
Testicle position	High-riding testicle, transverse alignment	Normal position, vertical alignment	Normal position, vertical alignment
Pyuria	Less likely	More likely	Less likely

GU, Genitourinary.
*Including epididymo-orchitis

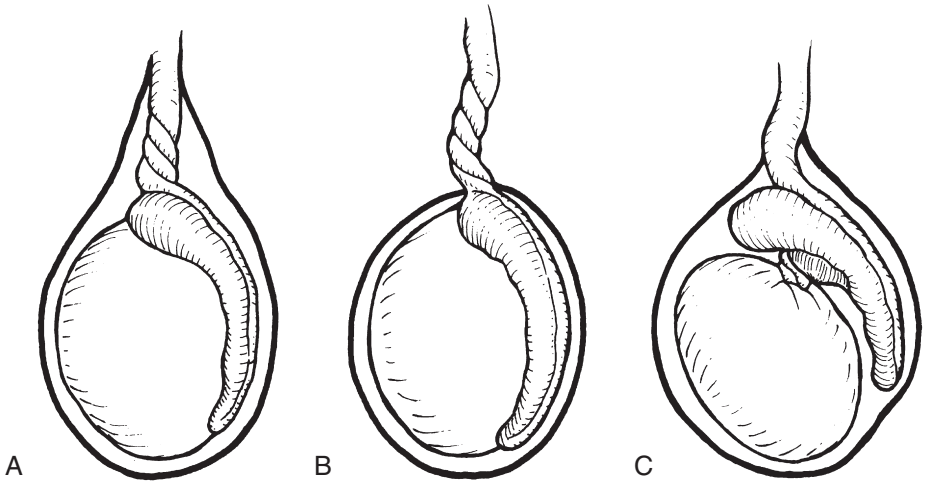

FIG. E1 Types of testicular torsion. A, Intravaginal torsion above the epididymis. **B,** Extravaginal torsion. **C,** Torsion of the testis below the epididymis. (From Rumack CM et al: *Diagnostic ultrasound,* ed 4, Philadelphia, 2011, Elsevier.)

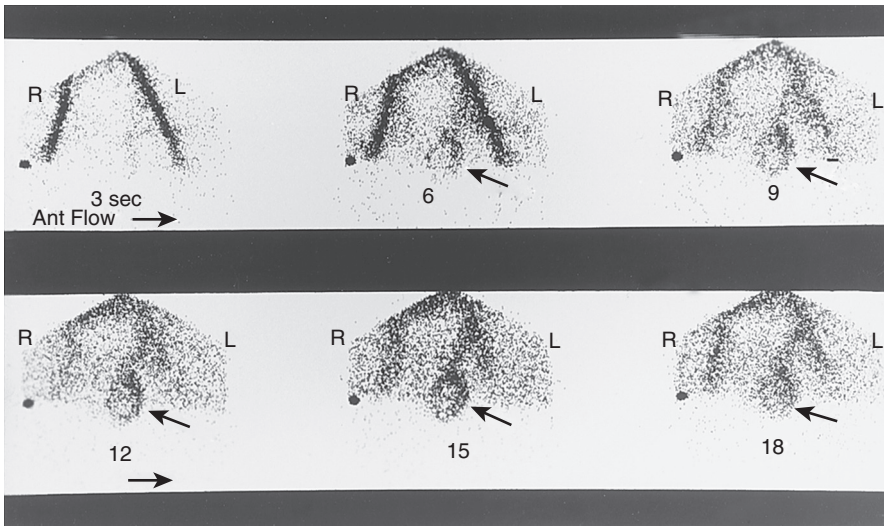

FIG. E2 Testicular torsion. Evaluation of blood flow to the testicle has been done by giving an intravenous bolus of radioactive material. The right and left iliac vessels are clearly identified, and sequential images are obtained every 3 seconds. Here, increased flow is seen to the rim of the left testicle *(arrows),* and there is no blood flow centrally. This is the appearance of a testicular torsion in which the torsion has been present for more than approximately 24 hr. *Ant,* Anterior. (From Mettler FA [ed]: *Primary care radiology,* Philadelphia, 2000, WB Saunders.)

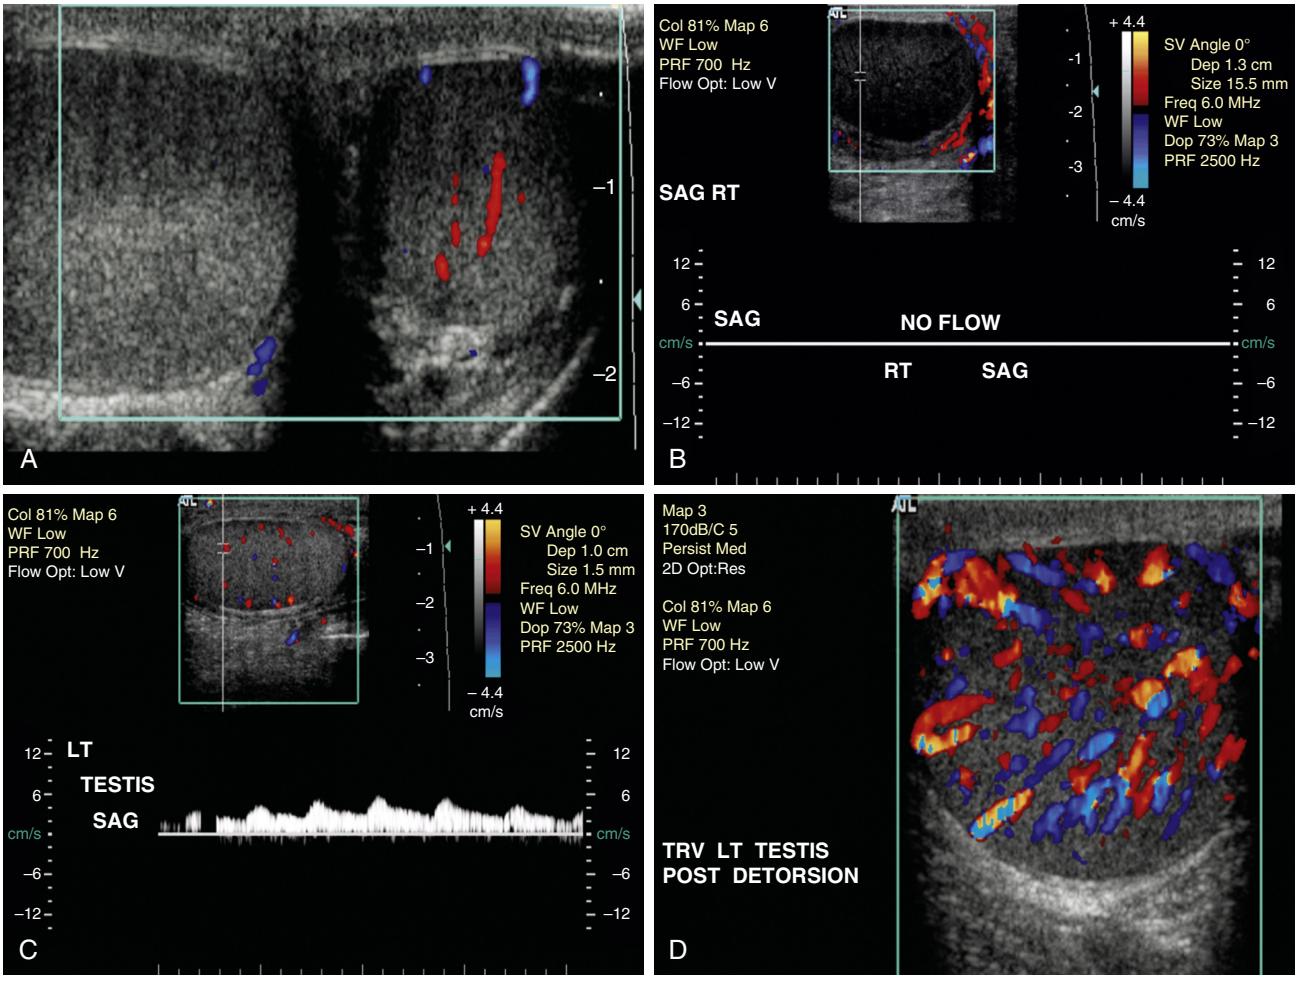

FIG. E3 Acute testicular torsion. **A** to **C,** This 13-year-old boy presented with acute, excruciating right-sided scrotal pain. **A,** Transverse gray-scale image of both testes demonstrates enlargement of the avascular right testis. **B,** Absence of both color and pulsed Doppler flow is noted on this sagittal image of the right testis. **C,** Normal pulsed and color Doppler flow confirmed in asymptomatic, normal-appearing left testis. **D,** Teenage boy with acute left-sided testicular torsion. Closed manual detorsion of the left testis was done at diagnosis in the ultrasound suite. Color Doppler sonogram of the left testis obtained immediately after detorsion shows dramatic hyperemia throughout the left testis. *LT,* Left; *RT,* right; *SAG,* sagittal; *TRV,* transverse. (From Rumack CM et al: *Diagnostic ultrasound,* ed 4, Philadelphia, 2011, Elsevier.)

BASIC INFORMATION

DEFINITION

Tetanus is a life-threatening illness manifested by muscle rigidity and spasms; it is caused by a neurotoxin (tetanospasmin) produced by *Clostridium tetani.*

SYNONYMS

Lockjaw
Generalized tetanus
Neonatal tetanus
Cephalic tetanus
Localized tetanus

ICD-10CM CODES
A33 Tetanus neonatorum
A34 Obstetrical tetanus
A35 Other tetanus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 264 cases between 2009 and 2017. Overall case fatality was 13.2%, but 31.3% for people over 65. More than 60% of cases were among people aged 20 to 64 yr. Diabetes, immunosuppression, and IVDA may be risk factors for tetanus. Diabetes accounted for 13% of cases and a quarter of all tetanus deaths. IVDA accounted for 17% of the cases.
INCIDENCE (WORLDWIDE): About 1 million cases of tetanus are reported worldwide annually, suggesting a global incidence of about 18 per 100,000 persons per yr and an estimated 300,000 to 500,000 deaths per yr. Tetanus is an expected complication when disasters strike in developing countries where tetanus immunization coverage is low.
PREDOMINANT AGE: >60 yr of age
GENETICS: Neonatal infection:

- Rare in the U.S.
- Among the leading causes of neonatal mortality in many parts of the world (caused by infection of the umbilical cord stump)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Trismus ("lockjaw")
- Risus sardonicus (peculiar grin), characteristic grimace that results from contraction of the facial muscles (Fig. E1)

FIG. E1 Facial muscle involvement in tetanus, producing characteristic "risus sardonicus." (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.)

- Generalized muscle spasms causing severe pain and, at times, respiratory compromise and death
- Rigid abdominal muscles, flexed arms, and extended legs (Fig. E2)
- Autonomic dysfunction several days after onset of illness
- Leading cause of death: Fluctuations in heart rate and blood pressure
- Usually, absence of fever
- Localized tetanus
  1. Rigidity of muscles near the injury
  2. Weakness as a result of lower motor neuron injury
  3. May be self-limited and resolve spontaneously
  4. More often progresses to generalized tetanus
  5. Cephalic tetanus:
     a. May occur with head injuries or chronic otitis with localized ear or mastoid infection with *C. tetani*
     b. Can manifest as cranial nerve dysfunction

ETIOLOGY

- *C. tetani* is a gram-positive, spore-forming bacillus (Fig. E3) that resides primarily in the soil.
- Majority of cases are caused by punctures and lacerations (Fig. E4).
- Toxin is elaborated from organisms in a contaminated wound.
- Local symptoms are caused by inhibition of neurotransmitter at presynaptic sites.
  1. Over the next 2 to 14 days, the toxin travels up the neurons to the CNS, where it acts on inhibitory neurons to prevent neurotransmitter release.
  2. Unopposed motor activity results in tonic contractions of muscles.

FIG. E2 Neonatal tetanus. (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Strychnine poisoning
- Dystonic reaction caused by neuroleptic agents: Neuroleptic malignant syndrome
- Local infection (dental or masseter muscle) causing trismus
- Severe hypocalcemia
- Hysteria

WORKUP

- Positive wound culture is not helpful in diagnosis.
- Isolation of organism is possible in patients without the illness.

LABORATORY TESTS

- Usually, normal blood counts and chemistries
- Toxicology of serum and urine to rule out strychnine poisoning

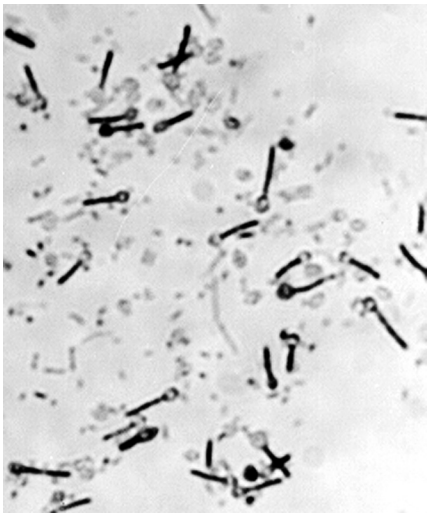

FIG. E3 *Clostridium tetani:* A gram-positive bacillus with terminal spores. (Courtesy J. Campbell, Oxford University Clinical Research Unit, Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam. From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.)

FIG. E4 Lacerations to the feet are the most common focus of *Clostridium tetani* infection. Note clawing of toes secondary to increased tone in surrounding muscles. (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Monitoring in a hospital ICU: Keep surroundings dark and quiet
- Intubation or tracheostomy for severe laryngospasm
- Prompt irrigation and debridement of wound to eliminate spores and necrotic tissue that can favor germination

ACUTE GENERAL Rx

- Passive immunization with human tetanus immunoglobulin (HTIG) 500 U as soon as possible via IM injection in thigh or deltoid muscle. Some studies recommend 3000 to 6000 U for generalized tetanus.
- Tetanus toxoid (Td) 0.5 ml by IM injection at a different site. Redose later for a total of 3 doses spaced at least 2 weeks apart to elicit active immunization.
- Antibiotics alone may fail without adequate debridement. Metronidazole 500 mg IV q6h to 8 h, or penicillin G 2 to 4 million U IV q4h to q6h for 7 to 10 days, or doxycycline 100 mg IV q12h.
- IV diazepam 10 to 30 mg to control muscle spasms. Alternative agents are midazolam, baclofen, IV magnesium sulfate, propofol, dantrolene, barbiturates, and chlorpromazine. Intrathecal antitoxin also can be used to control muscle spasms and avoid intubation.
- Neuromuscular blockade if necessary with pancuronium or vecuronium.
- Beta-blockers (e.g., labetalol: 0.25 to 1 mg/min) to control sympathetic hyperactivity.

CHRONIC Rx

- Supportive care. Beta-blockers (labetalol), magnesium sulfate, and morphine (0.5-1.0 mg/kg/h continuous infusion) can improve autonomic dysfunction
- Possible mechanical ventilation. Consider tracheostomy. If ventilator support is not available, benzodiazepines are the preferred agent to manage respiratory failure
- Minimal external stimuli
- Control of heart rate and blood pressure:
  1. Labetalol for sympathetic hyperactivity
  2. Pacemaker for sustained bradycardia
- Physical therapy once spasms subside

DISPOSITION

Full recovery over weeks to months if complications can be avoided

REFERRAL

- To emergency department
- To infectious disease specialist

PEARLS & CONSIDERATIONS

COMMENTS

- Illness is preventable. Table E1 describes tetanus prophylaxis in routine wound management.
- Boosters of Td should be given every 10 yr to maintain immune status.
- The tetanus-diphtheria-acellular pertussis vaccine (Tdap) may be used instead of Td, but if used, Tdap should be used only once in adults, except in pregnant women, who should receive Tdap during each pregnancy.
- Passive as well as active immunization (HTIG and Td) should be given for patients with tetanus-prone wounds who have not been adequately immunized in the previous 5 yr.
- A recent U.S. study showed that only 72% of people older than 6 yr had protective levels of antibody.

Tetanus (Patient Information)

AUTHOR: **Glenn G. Fort, MD, MPH**

TABLE E1 Tetanus Prophylaxis in Routine Wound Management

	Clean, Minor Wounds		Other Wounds*	
History of Absorbed Tetanus Toxoid	**Tdap or Td†**	**TIG‡**	**Tdap or Td†**	**TIG‡**
Uncertain, or <3 doses	Yes	No	Yes	Yes
3 or more doses	No§	No	No¶	No

DT, Diphtheria and tetanus toxoid vaccine; *DTaP,* combined diphtheria toxoid–tetanus toxoid–acellular pertussis vaccine; *Td,* tetanus toxoid and reduced diphtheria toxoid vaccine; *Tdap,* tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine; *TIG,* tetanus immune globulin.

*Such as, but not limited to, wounds contaminated with dirt, feces, or saliva; puncture wounds; avulsions; and wounds resulting from missiles, crushing, burns, and frostbite.

†For children <7 yr of age, DTaP is preferred to tetanus toxoid alone if <3 doses of DTaP have been given previously. If pertussis vaccine is contraindicated, DT is given. For persons ≥7 yr of age, Td (or Tdap for adolescents 11 to 18 yr of age) is preferred to tetanus toxoid alone. Tdap is preferred to Td for adolescents 11 to 18 yr of age who have never received Tdap. Td is preferred to tetanus toxoid for adolescents who received Tdap previously or when Tdap is not available.

‡TIG should be administered for tetanus-prone wounds in HIV-infected patients regardless of the history of tetanus immunizations.

§Yes, if ≥10 yr since the last tetanus toxoid–containing vaccine dose.

¶Yes, if ≥5 yr since the last tetanus toxoid–containing vaccine dose. (More frequent boosters are not needed and can accentuate adverse events.)

BASIC INFORMATION

DEFINITION

Tetralogy of Fallot (TOF) is a congenital heart deformity that consists of the following four features (Fig. E1):

1. Malalignment ventricular septal defect (VSD)
2. Infundibular stenosis and/or pulmonary valve stenosis that leads to the obstruction of the right ventricular (RV) outflow tract (less frequent subtypes include pulmonary valve atresia and absent pulmonary valve)
3. An aorta that overrides the VSD by <50% of its diameter with rightward conal deviation
4. Concentric RV hypertrophy (result of right ventricular outflow tract [RVOT] obstruction)

SYNONYM

TOF

ICD-10CM CODE
Q21.3 Tetralogy of Fallot

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- TOF is the most common cyanotic congenital heart defect.
- TOF accounts for nearly 3% to 5% of all cases of congenital heart disease.
- Occurs in approximately 0.28/1000 live births in the U.S.
- It is the most common cyanotic malformation to reach adulthood without reparative surgery.

PREDOMINANT SEX: Slightly higher incidence in males than females

GENETICS: Genetic influence is suspected (22q11 deletion).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Of the four major features of TOF, infundibular and pulmonary stenosis that lead to RV outflow tract obstruction and the presence of a VSD are the defects that result in abnormal intracardiac circulation and lead to clinical manifestations:
  1. Right-to-left shunting and hypoxemia
  2. Decreased pulmonary blood flow
  3. Altered RV hemodynamics
- The aforementioned pathophysiology results in common manifestations of TOF, including the following:
  1. Low birth weight and growth rate.
  2. Dyspnea on exertion.
  3. Physical examination findings:
     a. Cyanosis of the nail beds and lips
     b. Digital clubbing (less common as a result of early surgical correction)
     c. Palpable RV impulse
     d. Systolic thrill along the left sternal border
     e. Single second heart sound comprised of aortic component only
     f. A grade 3 to 5 crescendo/decrescendo systolic murmur is heard along the left mid to upper sternal border with posterior radiation (pulmonic stenosis)
  4. In TOF with pulmonary atresia, murmur is softened/absent and the patient is deeply cyanotic.
  5. Hypercyanotic ("tet") spells occur with events that cause sudden decreases in oxygenation, increase in right ventricular outflow tract obstruction/increase in pulmonary vascular resistance, or with decreased systemic vascular resistance leading to an increase in right to left shunting across the VSD. Hypercyanotic spells are characterized by paroxysmal episodes of worsening cyanosis and rapid and deep breathing. Provoking events include crying, defecation, and exercise. Relieved with increased systemic vasoconstriction (i.e., squatting). Prolonged episodes can result in syncope.
  6. The degree of RV outflow obstruction determines the age and symptoms at presentation. In neonates with severe obstruction, profound cyanosis may result from insufficient pulmonary blood flow. Cases with mild to moderate obstruction and adequate pulmonary flow ("pink tet") may be diagnosed while patient is being evaluated for murmur or heart failure.
  7. After repair, patients may have a low-pitched diastolic murmur at the pulmonic area that is consistent with pulmonary regurgitation or occasionally a pansystolic murmur that is consistent with a VSD patch leak. If the patient only has a palliative shunt, a continuous murmur may be heard over the chest on the side of the shunt.
  8. Fig. E2 shows the pathophysiologic mechanisms of a hypoxic (tet) spell.

ETIOLOGY

TOF results from the abnormal septation of the embryologic conotruncus and is associated with some genetic disorders, but the exact molecular mechanism leading to the defect is unknown.

DIAGNOSIS

- The diagnosis of TOF is suspected in any neonate, infant, or child who presents with cyanosis and a heart murmur (see "Physical Findings & Clinical Presentation").

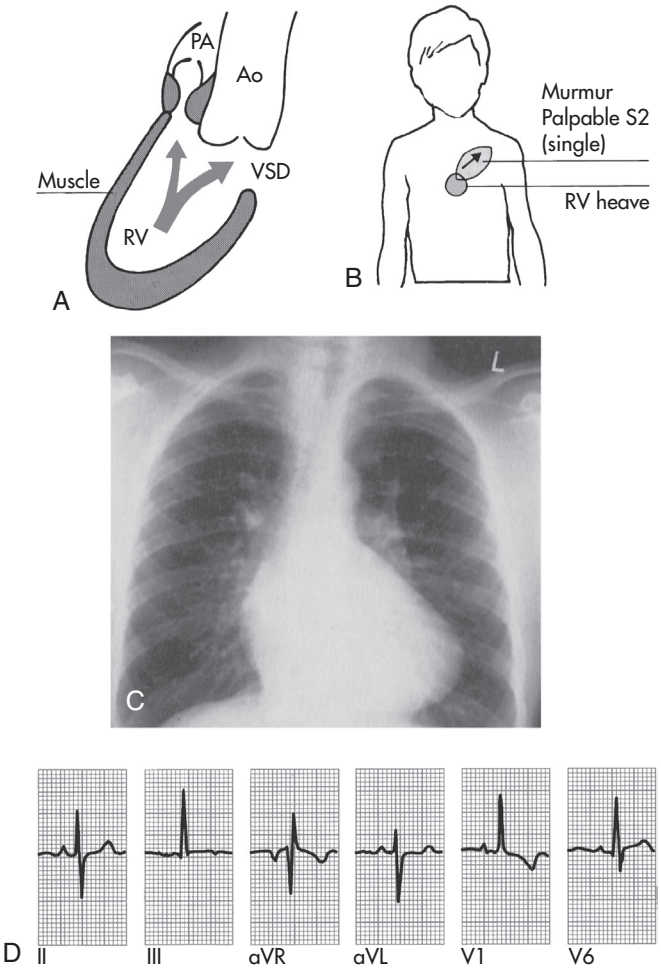

FIG. E1 Features of Fallot tetralogy. A, Diagram of abnormality. **B,** Physical signs. **C,** Chest x-ray showing right ventricular hypertrophy, typical "coeur en sabot." **D,** ECG showing right atrial and ventricular hypertrophy and right axis deviation. *Ao,* Aorta; *aVL,* augmented vector left; *aVR,* augmented vector right; *ECG,* electrocardiogram; *PA,* pulmonary artery; *RV,* right ventricle; *VSD,* ventricular septal defect. (From Souhami RL, Moxham J: *Textbook of medicine,* ed 4, London, 2002, Churchill Livingstone.)

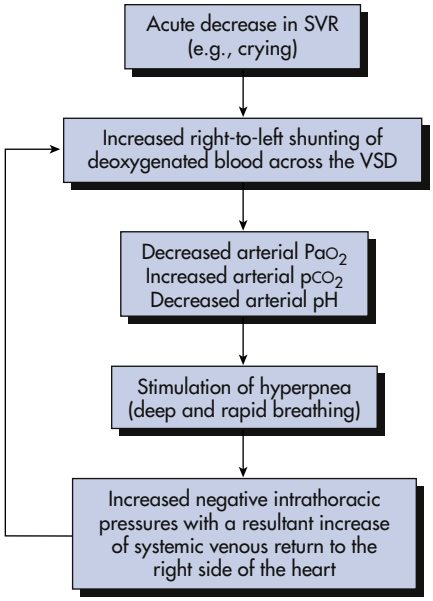

FIG. E2 Pathophysiologic mechanisms of a hypoxic (tet) spell. *PaO_2,* Partial pressure of oxygen in arterial blood; *pCO_2,* partial pressure of carbon dioxide; *SVR,* systematic vascular resistance; *VSD,* ventricular septal defect. (From Marx et al: *Rosen's emergency medicine: concepts and clinical practice,* 7 ed, 2010, Elsevier.)

- TOF is associated with other cardiac defects:
  1. Persistent foramen ovale/atrial septal defect
  2. Pulmonary artery anomalies
  3. Right aortic arch (25%)
  4. Left superior vena cava to coronary sinus (persistent left superior vena cava)
  5. Additional VSDs
  6. Coronary artery anomalies (LAD arising from RCA)
  7. Aortic valve regurgitation
- Associated anomalies and syndromes include the following:
  1. DiGeorge
  2. De Lange
  3. Goldenhar
  4. Klippel-Feil
  5. VACTERL
  6. CHARGE
  7. Pierre Robin
  8. Trisomies 21, 13, and 18
  9. Fetal alcohol
  10. Alagille
  11. MTHFR polymorphism

DIFFERENTIAL DIAGNOSIS

- Asthma
- Isolated VSD
- Pulmonary atresia
- Patent ductus arteriosus
- Aortic stenosis
- Pneumothorax

WORKUP

- Detailed history and physical examination, including pulse oximetry
- Echocardiogram, chest radiograph, 12-lead ECG, and routine laboratory tests

LABORATORY TESTS

- Pulse oximetry to determine oxygenation.
- The CBC shows polycythemia from long-standing hypoxemia.
- Arterial blood gas levels show hypoxemia, normal pH, and pCO_2 (carbon dioxide levels).

DIAGNOSTIC STUDIES

- ECG commonly demonstrates right axis deviation, RV hypertrophy, and right atrial enlargement.
- Exercise testing may help to evaluate functional capacity and exertional arrhythmias.
- Chest radiography reveals a boot-shaped heart that is commonly described as *coeur en sabot;* a prominent RV with decreased pulmonary vascularity; and a heart size that is usually normal. However, in patients with increased aortopulmonary collateral blood flow or with associated large patent ductus arteriosus, the heart size is increased with increased pulmonary vascularity.
- Echocardiography demonstrates VSD(s), anatomy and severity of right ventricular outflow tract obstruction, and aortic arch anatomy.
- Cardiac catheterization and angiography help to determine hemodynamics, the severity of right-to-left shunting, the localization of the VSD, coronary artery anatomy, right ventricular outflow obstruction, pulmonary artery stenosis, and assessment of aortopulmonary collaterals. Catheterization should be performed by centers with experts in ACHD and should be performed before intervention for RVOT obstruction to delineate coronary artery delineation with coronary artery compression testing (Class I, Level of evidence B) as the LAD may arise from the RCA crossing the RVOT.
- Cardiac MRI (CMR) can be used for the localization of a residual VSD after prior surgery and is the gold standard for serial anatomic assessment of the RV outflow tract, the assessment of RV volumes and function, the quantification of degree of pulmonary regurgitation, and the detection of RV myocardial fibrosis. Magnetic resonance angiography (MRA) can be a noninvasive alternative to cardiac catheterization for the evaluation of pulmonary vascular anatomy and the ascending aorta. 3D echocardiography can be a supplemental tool for evaluation of need for pulmonary valve replacement.
- Multislice spiral computed tomography may occasionally be used for diagnosis, and may be helpful during the planning of the repair procedure when the anatomy is unusual or complex. Its use in children may be limited by the risks associated with radiation exposure. It can also be used to make assessments that are similar to those usually made by MRI for patients who are unable to undergo MRI (such as those with permanent pacemakers).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Oxygen
- Prostaglandins at time of birth to keep a patent ductus and to maintain ductal flow to the lungs
- Knee-chest position during hypoxemic spells to help reduce venous return and to increase systemic vascular resistance, thereby decreasing right-to-left shunting

ACUTE GENERAL Rx

- The acute treatment of any infant or child with TOF who is cyanotic with respiratory distress is aimed at increasing systemic vascular resistance and decreasing right-to-left shunting (e.g., phenylephrine 0.1 to 0.5 mcg/kg/min intravenously to increase systemic vascular resistance, and oxygen and morphine to decrease pulmonary vascular resistance).
- Intravenous sodium bicarbonate for metabolic acidosis and, if more is necessary, respiratory support with intubation and sedation are required to control respiratory distress in cyanotic spells.
- Intravenous β-blockers (propranolol) are used to decrease RV outflow tract contractility.
- Emergent complete surgical repair or subclavian artery to pulmonary artery shunt (Blalock-Taussig shunt) is required if all of the previous treatments fail.

CHRONIC Rx

- Palliative surgery includes procedures to increase pulmonary blood flow, thus improving oxygen saturation and allowing for pulmonary artery growth. Examples of palliative procedures include the modified Blalock-Taussig shunt, in which a Gore-Tex tube is used to create a connection between the subclavian artery and the pulmonary artery; the Waterston shunt, which attaches the ascending aorta to the right pulmonary artery; and the Potts shunt, which attaches

the descending aorta to the left pulmonary artery (the latter two operations are no longer performed as they tended to lead to unpredictable pulmonary blood flow). These are generally performed in patients who are not candidates for complete surgical repair due to prematurity, hypoplastic pulmonary arteries, and/or coexistent cardiac anomalies.
- Complete surgical repair has good success and involves closing the VSD with a Dacron patch and relieving the RV outflow tract obstruction by resection of the infundibular stenosis, patch augmentation of the RV outflow, or the placement of a transannular patch. Surgical outcomes are superior if surgery is allowed to be delayed until the age of 3 to 6 mo when feasible. Following surgical repair most patients have dramatic improvement in symptoms and are generally able to lead a relatively normal life.
- Postoperative issues include the following:
  1. Residual pulmonic regurgitation
  2. Progressive RV dilation and dysfunction from pulmonary regurgitation leading to need for pulmonary valve replacement
  3. Residual RV outflow tract obstruction
  4. Branch pulmonary artery stenosis or hypoplasia
  5. Sustained ventricular tachycardia
  6. Sudden cardiac death
  7. Atrioventricular block, atrial flutter, and atrial fibrillation
  8. Progressive aortic regurgitation
  9. Syndromal associations

DISPOSITION

- In the current era, almost all patients with TOF have either palliative or complete surgical repair before they reach adulthood.
- <3% of patients with TOF survive to 40 yr without surgery.
- Survival after successful complete operative repair of TOF is excellent (35-yr survival rate for patients after TOF repair is 85%).
- Adults who underwent palliative surgery during childhood can present with cyanosis and clubbing, polycythemia, and pulmonary hypertension where there is excessive pulmonary blood flow.
- Pulmonary regurgitation (PR), residual pulmonary stenosis, and tricuspid regurgitation are the most common long-term sequelae in adults who underwent repair in childhood.
- Current guidelines and studies support pulmonary valve replacement with a bioprosthesis if there is moderate to severe PR with cardiovascular symptoms (Class I, level of evidence B) or in asymptomatic patients with evidence of ventricular enlargement/dysfunction in a setting of moderate to severe PR (Class IIa, level of evidence B). Pulmonary valve replacement is also reasonable if at least 2 of the following are present: RV diastolic volume by cardiac MRI is >160 ml/m^2 or RV systolic volume >80 ml/m^2, mild or greater RV or LV dysfunction, RV end diastolic volume >2 times the LV end diastolic function, RV systolic pressure 2/3 of systemic pressure or higher, reduction in exercise capacity. Pulmonary valve replacement can be performed either surgically or percutaneously.
- MRI or echocardiographic right ventricular global longitudinal strain assessment is a useful method to quantify remodeling of the right ventricle after repaired TOF and can guide management.
- Aortic root dilatation and aortic regurgitation are less common long-term issues. Aortic dissection is extremely rare in patients with TOF.
- Ventricular arrhythmia can lead to sudden cardiac death (SCD), and risk increases with time after surgical repair, particularly in the third and fourth decades of life (incidence of approximately 2% per decade). Monomorphic ventricular tachycardia is likely the result of a reentry circuit from an isthmus in the RV outflow tract due to scar caused by surgical repair. Patients are also susceptible to polymorphic VT/VFib due to progressive RV/LV dilation similar to other dilated cardiomyopathies. ICD is indicated for secondary prevention of SCD. Primary prevention ICD is indicated in patients who meet standard criteria (i.e., LVEF <35% with NYHA class II or III symptoms) and can be considered in those with additional risk factors that have been identified for SCD such as nonsustained ventricular tachycardia, QRS duration >180 ms, LV dysfunction, and extensive RV fibrosis on CMR. In those with moderate risk for SCD, programmed ventricular stimulation can assist in risk stratifying (Class IIa, level of evidence B).
- Atrial tachyarrhythmias are more prevalent than ventricular arrhythmias. Predisposition may be from scars at prior surgical access sites or from atrial dilation.
- A prolonged QRS duration on the preoperative ECG predicts an increased risk of postoperative supraventricular or ventricular arrhythmia. Prolongation of the QRS beyond 180 msec identifies patients who are at increased risk of ventricular tachycardia after surgery.
- Patients with signs or symptoms of arrhythmia may need to undergo invasive electrophysiologic testing and may require mapping and/or ablation of arrhythmias, antiarrhythmic medications, or the placement of an implantable cardiac defibrillator.
- Reduced exercise capacity is frequently the result of chronic pulmonary regurgitation or residual RV outflow tract obstruction.
- Patients with left ventricular dysfunction may benefit with angiotensin-converting enzyme inhibitors, β-blockers, and diuretics.
- Women with repaired TOF should be assessed by a cardiologist before considering pregnancy to determine if pulmonic valve replacement is needed first, as severe pulmonary regurgitation and RV dysfunction are associated with cardiac events during pregnancy, although many will tolerate pregnancy and delivery well. Consult with a geneticist prior to pregnancy should be offered (Class I, level of evidence B).
- Selected patients with normal RV pressures and function without evidence of residual shunt and without atrial or ventricular tachyarrhythmia are eligible to participate in competitive sports.

REFERRAL

- Infants and children with cyanotic heart disease should be referred to a pediatric cardiologist for further diagnostic evaluation. After being diagnosed with TOF, patients should be referred to centers with experience in palliative and complete surgical repair.
- Adult patients with repaired TOF should be comanaged with a cardiologist who specializes in adults with congenital heart disease. Routine followup is based on burden of symptoms and cardiac dysfunction, but the patient should be seen on at least an annual basis.

PEARLS & CONSIDERATIONS

- TOF was first described by the French physician Etienne Fallot in 1888.
- The first palliative surgical treatment for TOF was performed by Dr. Alfred Blalock at Johns Hopkins University in 1945 (i.e., the Blalock-Taussig shunt).
- The first surgical repair for TOF was performed by Dr. C. Walton Lillehei at the University of Minnesota in 1954.

COMMENTS

- The severity of RV outflow tract obstruction is the primary determinant of clinical symptoms and outcomes.
- There is a 3% increased risk of congenital heart disease in the children of parents with TOF.
- Unrepaired TOF requires subacute bacterial endocarditis prophylaxis before any dental work or nonsterile surgical procedures (e.g., surgery of the bowel or bladder).
- Children with TOF are at risk for neurodevelopmental delay when they reach school age.

BASIC INFORMATION

DEFINITION

Thalassemias are a heterogeneous group of disorders of hemoglobin synthesis. Patients with thalassemia have abnormalities of synthesis of one of the alpha- or beta-globin chains. Patients with thalassemia have an excess of either alpha-globin chains or beta-globin chains, which impair red blood cell production and may decrease red blood cell survival. Table E1 summarizes clinical syndromes of thalassemias.

SYNONYMS

Mediterranean anemia
Cooley anemia

ICD-10CM CODES

D56	Thalassemia
D56.0	Alpha thalassemia
D56.1	Beta thalassemia
D56.2	Delta-beta thalassemia
D56.3	Thalassemia trait
D56.4	Hereditary persistence of fetal hemoglobin (HPFH)
D56.8	Other thalassemias
D56.9	Thalassemia, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Thalassemia is among the most common genetic disorder worldwide. Approximately 4.83% of the world's population carries globin variants, including 1.67% of the population that are heterozygous for alpha-thalassemia and beta-thalassemia.
- The highest concentration of alpha-thalassemia is found in Southeast Asia and the African west coast. The prevalence is 5% to 10% in Thailand and approximately 5% among blacks.
- The worldwide prevalence of beta-thalassemia is approximately 3%; it is 15% to 30% in certain regions of Italy and Greece.
- The distribution of thalassemia in Europe, Africa, and Asia parallels that of malaria, suggesting that thalassemic persons are more resistant to the parasite, thus permitting evolutionary survival advantage.

CLASSIFICATION

Beta-thalassemia:

- It is increasingly common to classify thalassemia as transfusion dependent versus nontransfusion dependent. Historically, beta thalassemia has been classified as thalassemia minor, intermedia, and major
- Thalassemia minor: Associated with low normal Hgb or mild, asymptomatic anemia and microcytosis, with no organ failure
- Thalassemia major: PRBC transfusion dependence with severe complications related to bone marrow expansion and iron overload
- Thalassemia intermedia: In-between thalassemia minor and major; typically with Hgb 7.0 and 11.0 g/dl without transfusion dependence, but may have complications more typical of thalassemia major
- The designation beta+ (β^+) or beta-0 (β^0) is used to describe the severity of the beta-globin gene abnormality when combined with other abnormal Hgb, β^+ indicating a mild abnormality, β^0 a severe abnormality, usually from absent beta-globin gene synthesis. For example, β^0/Hgb S is more severe than β^+/Hgb S disease
- Other variant beta-globin gene abnormalities:
  1. Hemoglobin E, common in Southeast Asia, an abnormal Hgb caused by a Glu → Lys substitution at position 26 of the beta-globin chain. The resulting mRNA is unstable, causing decreased Hgb E production and a picture of beta thalassemia. Homozygous Hgb E is associated with mild anemia and microcytosis, similar to thalassemia minor, and is not usually symptomatic. Hgb E inherited with other beta globin abnormalities (e.g., β^0 thalassemia) may cause clinically significant anemia
  2. Delta-beta-thalassemia (total absence of both delta-globin and beta-globin synthesis)
  3. Lepore hemoglobin (synthesis of small amounts of fused delta-beta-globin and total absence of delta- and beta-globin)
  4. Hereditary persistence of fetal hemoglobin (HPHF) (increased hemoglobin F synthesis and reduced or absence of delta- and beta-globin)

Alpha-thalassemia:

- The alpha globin genes are found on chromosome 16, two on each. Alpha$^+$ refers to a chromosome with one gene missing (most common cause) or dysfunctional. Alpha^0 indicates that two genes are missing (most common) or dysfunctional. The severity of the abnormality depends on the number of deleted genes.
- Silent carrier (one alpha globin gene missing).
- Alpha-thalassemia trait (two alpha-globin genes missing). It is important to know in this situation whether the two genes are on the same or different chromosomes because this has genetic counseling consequences (risk of hydrops fetalis or Hgb H disease).
- Hemoglobin H disease (three alpha-globin genes missing). Hgb H is formed when excess beta-globin chains self-associate—that is, instead of two alpha and two beta-globin chains, the Hgb has four beta-globin chains (β^4). It is unstable and associated with anemia and hemolysis.
- Hydrops fetalis (all alpha-globin genes missing).
- Hemoglobin constant spring (Hgb_{cs}) is a "nondeletional" alpha thalassemia variant, that is, the gene is present but abnormal. Hgb_{cs} is caused by a mutation in the stop codon in the alpha-globin gene; the alpha chain is 31 amino acids longer, but is produced at only 1% of normal. It is common in Southeast Asia.

Thalassemic hemoglobinopathies:

- Hb Terre Haute, Hb Quong Sze, HbE, Hb Knossos

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Beta-thalassemia:

- Heterozygous beta-thalassemia (thalassemia minor): No or mild anemia, microcytosis and hypochromia, mild hemolysis, and splenomegaly
- Homozygous beta-thalassemia (thalassemia major): Intense hemolytic anemia; transfusion dependency; bone deformities (skull and long bones [Figs. E1 to E5]); osteopenia, hepatomegaly; splenomegaly; iron overload leading to cardiomyopathy, diabetes mellitus, and hypogonadism; growth retardation; pigment gallstones; susceptibility to infection, pulmonary hypertension, thrombophilia,

TABLE E1 Clinical Syndromes of Thalassemia

Clinically Asymptomatic

Silent carriers

α^+ thalassemia heterozygotes (some cases)

Rare forms of β-thalassemia heterozygosity

Thalassemia Minor (Low MCH and MCV, with or without Mild Anemia)

α^+ thalassemia heterozygotes (some cases)

α^0 thalassemia heterozygotes

α^+ thalassemia homozygotes

β^0 thalassemia trait

β^+ thalassemia trait

Some cases of hemoglobin E/β-thalassemia

Thalassemia Intermedia (Transfusion Independent)*

Some β^+/β^+ thalassemia homozygotes and compound heterozygotes

Interaction of β^0/β^0, β^0/β^+, or β^+/β^+ with αthalassemia

Interaction of β^0/β or β^+/β with triple α

Hemoglobin H disease

α^0/hemoglobin Constant Spring thalassemia

$\beta^0/\delta\beta$ or $\beta^+/\delta\beta$ thalassemia compound heterozygotes

$\delta\beta/\delta\beta$-thalassemia

Some cases of hemoglobin E/β-thalassemia and hemoglobin Lepore/β-thalassemia

Rare cases of heterozygotes for β-thalassemia mutation, particularly involving exon 3 ("dominant β-thalassemia")

Thalassemia Major (Transfusion Dependent)

β^0/β^0 thalassemia

β^+/β^+ thalassemia

β^0/β^+ thalassemia

Some cases of β^0/hemoglobin Lepore and β^+/hemoglobin Lepore thalassemia

Some cases of β^0/hemoglobin E and β^+/hemoglobin E thalassemia

MCH, Mean cell hemoglobin; *MCV,* mean cell volume.
*β-thalassemia intermedia is defined as a symptomatic condition in which regular transfusion is not essential to maintain life; however, some patients have a poor quality of life and may benefit from transfusion as their condition progresses (e.g., when there is increasing splenomegaly).
From Bain BJ et al: *Dacie and Lewis practical haematology,* ed 12, Philadelphia, 2017, Elsevier.

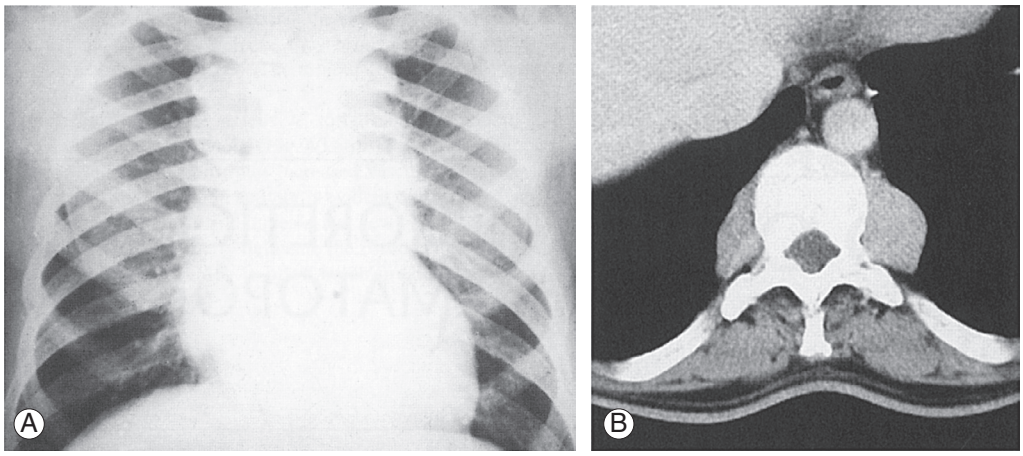

FIG. E1 Thalassemia. A, Lobulated soft tissue masses due to extramedullary hematopoiesis are present adjacent to the thoracic spine. **B,** In another patient, paravertebral extramedullary hematopoietic tissue is shown in the lower sections of a computed tomography examination of the thorax. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

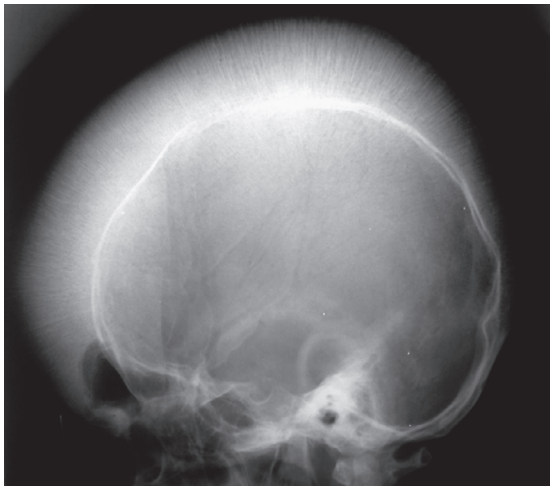

FIG. E2 Thalassemia. Lateral SXR (skull x-ray) showing gross expansion of the diploë and loss of definition of the outer table with sparing of the occipital bone. A gross "hair-on-end" appearance is shown. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

FIG. E3 Thalassemia. Sagittal T1-weighted image of the ankle showing diffuse reduction of marrow signal intensity due to reconversion. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

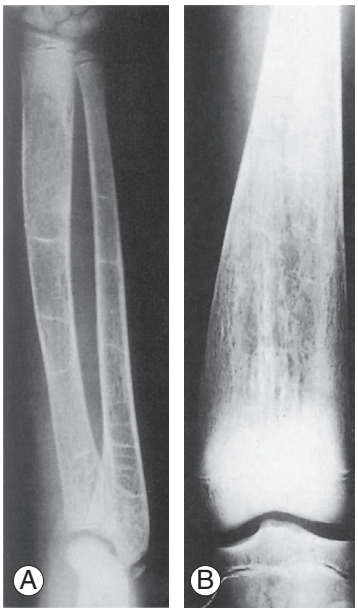

FIG. E4 Thalassemia. A, Considerable bone expansion, cortical thinning, and simplification of the trabecular pattern. **B,** Considerable marrow expansion has produced a flask shape of the distal femur. The coarsened trabecular pattern and cortical thinning are obvious. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

FIG. E5 Thalassemia (boy aged 7). Gross marrow hyperplasia has expanded and thinned overlying cortical bone. Medullary trabeculae have been destroyed, and the residual ones are coarsened. Inset: Early changes of the same type in a finger of a child aged 4 yr. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

hematopoietic "pseudotumors" (areas of hematopoiesis outside the marrow that may cause morbidity such as nerve compression)
- Thalassemia intermedia is a spectrum of disorder of resembling thalassemia major but manageable without transfusion therapy

Alpha-thalassemia:
- Silent carrier: No symptoms, often low normal MCV
- Alpha-thalassemia trait: Mild microcytic anemia, no symptoms
- Hemoglobin H disease: Moderately severe hemolysis with microcytosis and splenomegaly
- The loss of all four alpha-globin genes is incompatible with life (stillbirth of hydropic fetus). NOTE: Pregnancies with hydrops fetalis are associated with a high incidence of toxemia

ETIOLOGY

- Beta-thalassemia: It is caused by more than 200 point mutations and, rarely, by deletions. Many of these mutations decrease the amount of beta-globin produced to varying degrees, accounting for the spectrum of disease. The reduction of beta-globin synthesis results in excess, unbound alpha-globin chains that are cytotoxic and cause intramedullary hemolysis and ineffective erythropoiesis. The pathophysiology of beta-thalassemia is illustrated in Fig. E6. Hgb A_2 and fetal hemoglobin (Hgb F) may be increased.
- Alpha-thalassemia: Duplication of the α-globin chain on chromosome 16 results in 4α-globin genes ($\alpha\alpha/\alpha\alpha$); α-thalassemia results from

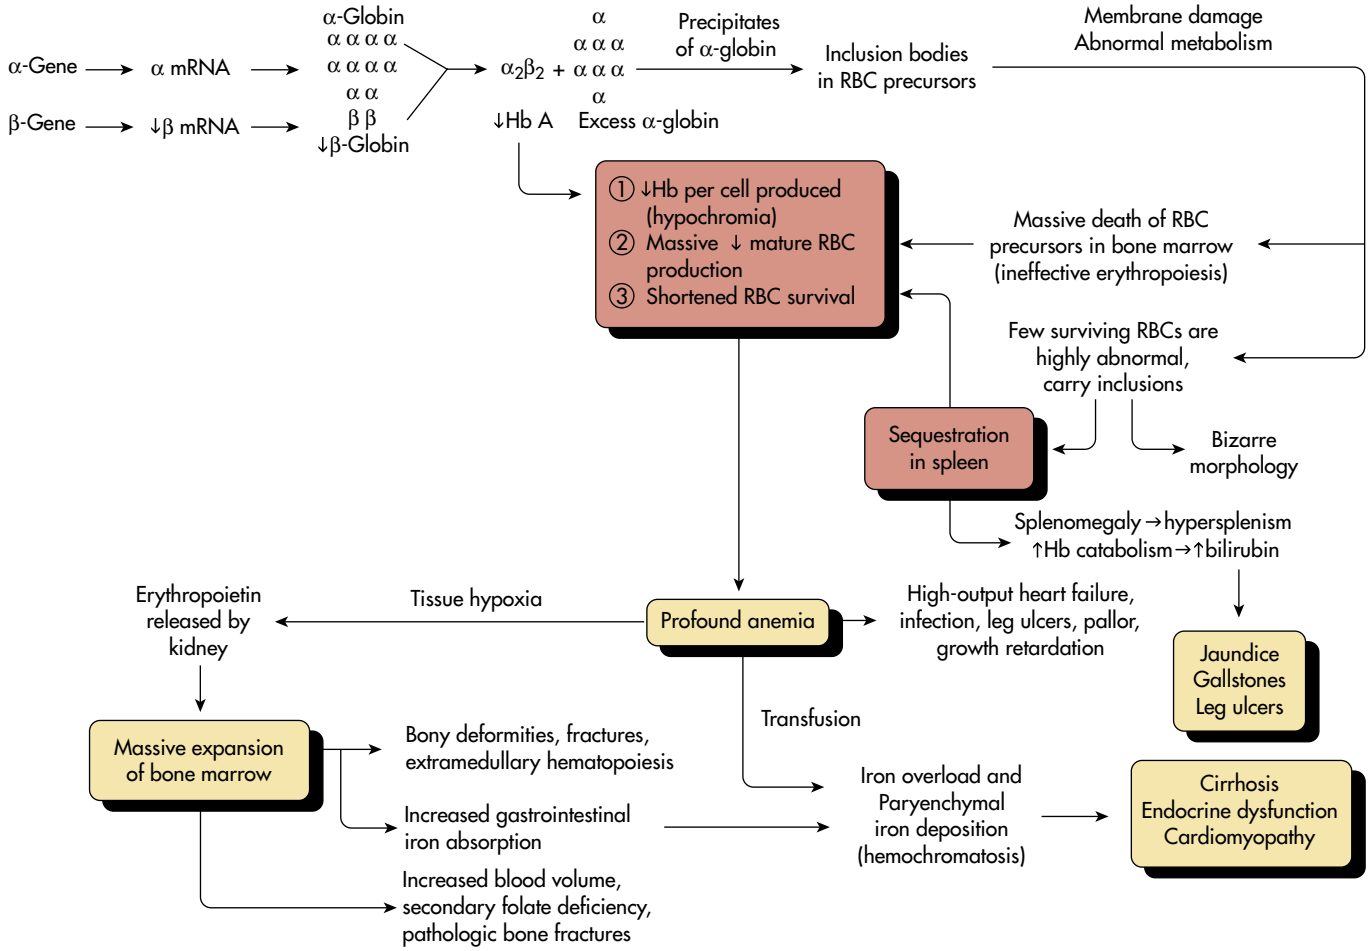

FIG. E6 Pathophysiology of severe forms of β-thalassemia. The diagram outlines the pathogenesis of clinical abnormalities resulting from the primary defect in β-globin chain synthesis. *Hb,* Hemoglobin; *RBC,* red blood cell. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

deletion or dysfunction (usually deletion) of one or more of these. Excess beta-globin chains may self-associate to form Hgb H (β^4), which is unstable and causes chronic hemolytic anemia.

Dx DIAGNOSIS

LABORATORY TESTS (TABLE E2, FIG. E7)

Beta-thalassemia:

- Microcytosis (mean cell volume: 55-80 fL)
- Mild anemia (Hgb <13.0 g/dl) with normal absolute RBC number
- Normal red blood cell (RBC) distribution width index (RDW)
- Smear (Fig. E8): Nucleated RBCs, target cells, anisocytosis, poikilocytosis, polychromatophilia, Pappenheimer and Howell-Jolly bodies
- Hemoglobin electrophoresis: Variable increase in hemoglobin A_2 and possibly increased Hemoglobin F
- Hemolysis: Elevated indirect bilirubin and lactate dehydrogenase, decreased haptoglobin

Alpha-thalassemia:

- Microcytosis without iron deficiency
- Hemoglobin electrophoresis normal (though Hgb H seen in hemoglobin H disease)
- Alpha-globin chain analysis may be performed at a reference laboratory and may be important for genetic counseling purposes, especially with alpha thalassemia trait

Rx TREATMENT

- Thalassemia minor: No treatment, but avoid iron administration for incorrect diagnosis of iron deficiency.
- Beta-thalassemia major (and hemoglobin H disease):
  1. PRBC transfusion therapy: Standard guidelines are available (Tables E3, E4, E5). For patients requiring transfusions for symptoms or to suppress complications, maintaining the pretransfusion hemoglobin level at 9 to 10.5 g/dl is typically recommended, with some patients (heart disease or other complications) benefiting from a target of 11 to 12 g/dl. To minimize the risk of complications, extended phenotyping of RBC is used for matching RBC in regularly transfused patients. RBCs are leukoreduced.
  2. Chelation therapy: Iron overload (transfusion hemosiderosis) is the major cause of late morbidity and mortality in patients with transfusion-dependent thalassemia. Serum ferritin <1000 ng/ml is associated with minimal risk of organ injury. MRI is used to assess hepatic and cardiac iron overload. Three iron chelators are available:
     a. Deferasirox (oral, first line in the U.S.), 20 to 40 mg/kg/day (transfusion dependent), 5 to 20 mg/kg/day (nontransfusion dependent).
     b. Deferoxamine (intravenous/subcutaneous) 75 to 100 mg/kg over 8 to 12 h 5 days/wk.
     c. Deferiprone (oral) 75 to 100 mg/kg/day.
  3. Splenectomy can decrease or eliminate transfusion requirement in thalassemia intermedia and for symptoms of enlarged spleen. Splenectomy increases infections, thrombotic complications, and pulmonary hypertension in thalassemia.
  4. Hematopoietic stem cell transplantation (HSCT): Allogenic transplantation should be considered in patients with severe disease before the onset of end-organ damage. Although HSCT is the only curative approach available, it has been limited by the high cost and scarcity of

TABLE E2 Laboratory Findings in Thalassemia

MCH, Mean cell hemoglobin; *MCV,* mean cell volume; *N,* normal.
Bain BJ et al: *Dacie and Lewis practical haematology,* ed 12, Philadelphia, 2017, Elsevier.

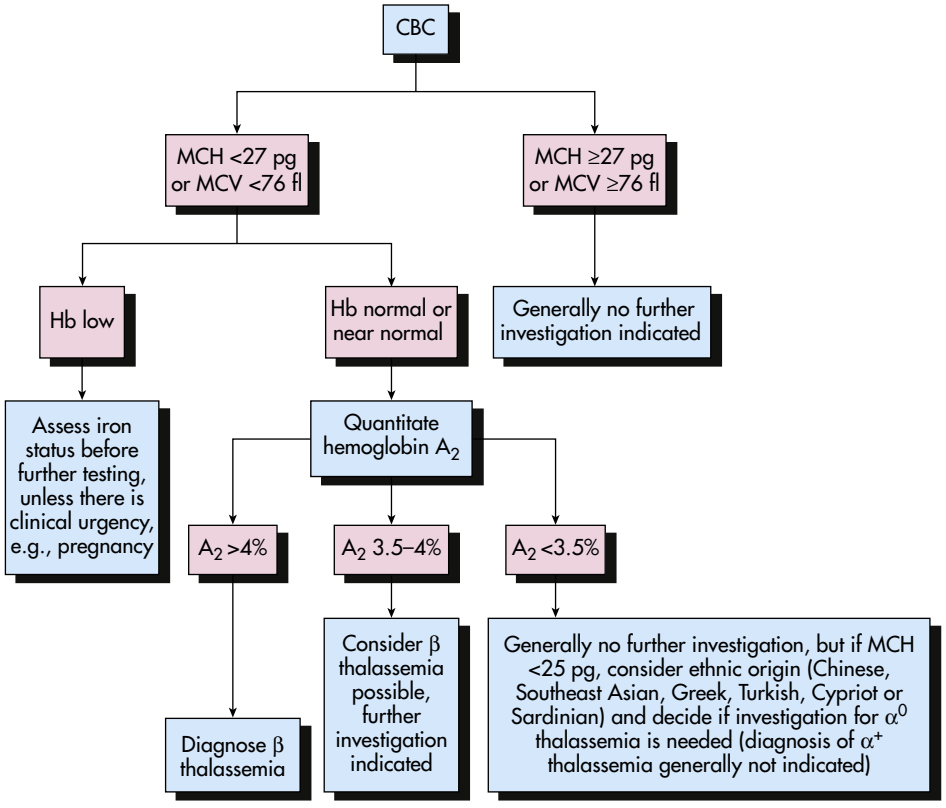

FIG. E7 Suggested scheme of investigation for thalassemia. (From Bain BJ et al: *Dacie and Lewis practical haematology,* ed 12, Philadelphia, 2017, Elsevier.)

human leukocyte antigen (HLA)-matched donors and carries a 5% to 10% transplant related mortality risk. Before transplantation, it is necessary to administer myeloablative regimens to eradicate the endogenous thalassemic bone marrow. Alternative donors (HLA-matched unrelated donor, unrelated cord blood, HLA-haploidentical relative) have been increasingly explored, translating into the expansion of the number of patients treatable with HSCT.

5. Exciting results have been obtained in early studies in 22 transfusion-dependent β-thalassemia patients with gene therapy. Autologous cells were transduced ex vivo with LentiGlobin BB305 vector, which encodes adult hemoglobin (HbA); the cells

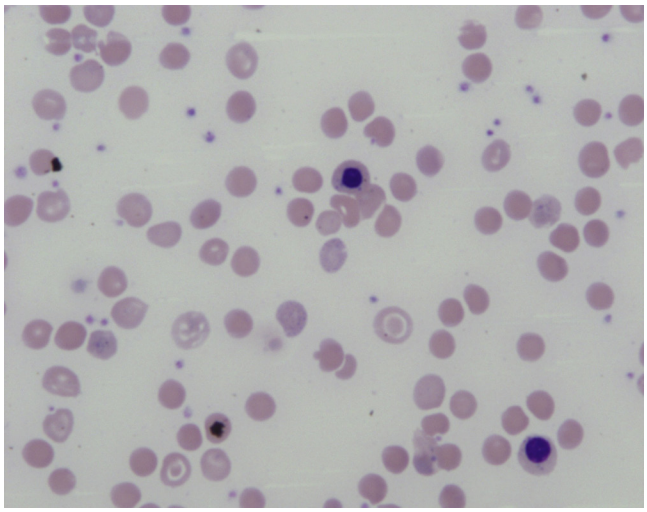

FIG. E8 Morphologic appearance of the peripheral blood film in a case of severe β-thalassemia. Note the bizarre cells, hypochromia, nucleated red blood cells, target cells, and polychromasia. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

were then reinfused after the patients had undergone myeloablative busulfan conditioning. This procedure reduced or eliminated the need for long-term red-cell transfusions in all patients with severe β-thalassemia without serious adverse events related to the drug product.

6. This product, named Zynteglo, has gained conditional market approval from the European Commission to treat transfusion-dependent β-thalassemia in patients >12 yr who have no other treatment options.
7. Members of the transforming growth factor β superfamily of ligands, including growth differentiation factors and activins, have been shown to act as inhibitors of late-stage erythropoiesis. Luspatercept is a novel recombinant fusion protein that acts as a trap for the transforming growth factor β superfamily of ligands. It was recently approved for treatment of anemia in adult patients with beta-thalassemia who require regular red blood cell transfusions.
8. Organ-specific toxicity should be managed with standard agents and protocols—for example, bisphosphonates for osteopenia and sildenafil citrate for pulmonary hypertension. Hematopoietic pseudotumors are managed with radiation, surgery, and transfusion.

PEARLS & CONSIDERATIONS

- Polymerase chain reaction can be used to detect point mutations or deletions in chorionic villous samples, enabling first-trimester, DNA-based testing for thalassemia.
- Genetic counseling is recommended for patients with thalassemia considering starting a family.

TABLE E3 Indications to Initiate Regular Transfusion Therapy in Nontransfusion-dependent Thalassemia

- Declining hemoglobin with enlargement of the spleen
- Growth failure
- Poor school performance
- Pregnancy
- Surgery
- Decreased exercise tolerance
- Failure of secondary sexual development
- Bony changes
- Frequent hemolytic crisis (hemoglobin H disease)
- Poor quality of life
- Primary prevention and management of the following:
  - Thrombotic or cerebrovascular disease
  - Pulmonary hypertension/heart failure
  - Extramedullary hematopoiesis
  - Leg ulcers

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

Thoracic Outlet Syndrome PTG ALG

BASIC INFORMATION

DEFINITION

Thoracic outlet syndrome (TOS) describes a condition producing upper extremity symptoms believed to result from neurovascular compression at the thoracic outlet (Fig. E1, Table 1). Three types are described on the basis of point of compression: (1) cervical rib and scalenus syndrome, in which abnormal scalene muscles or the presence of a cervical rib may cause compression; (2) costoclavicular syndrome, in which compression may occur under the clavicle; and (3) hyperabduction syndrome, in which compression may occur in the subcoracoid area. The compression occurs in three anatomical structures: arteries, veins, and nerves. TOS usually is caused by a combination of two factors: (1) having abnormal anatomy that creates compression in the thoracic outlet, (2) having some injury at the thoracic outlet.

- Neurogenic TOS: Caused by compression of brachial nerve plexus
- Arterial TOS: Caused by subclavian artery compression
- Venous TOS: Caused by compression of subclavian vein

SYNONYM

TOS

ICD-10CM CODE
G54.0 Brachial plexus disorders

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: TOS is an uncommon disorder. Varies from source to source; presence of cervical ribs in 0.5% to 1% of population (50% bilateral), but most are asymptomatic. Approximately 90% of all TOS disorders are neurogenic, and the remaining 10% are arterial or venous.
PREDOMINANT SEX: Females affected more often than males (ratio of 3.5:1)
PREDOMINANT AGE: Rare in those aged <20 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms and signs are related to the degree of involvement of each of the various structures at the level of the first rib.
- True venous or arterial involvement is not common.
- Diagnosis is most often used in the consideration of neural pain affecting the arm, which suggests involvement of the brachial plexus.
  1. Arterial compression: Pallor, paresthesias, diminished pulses, coolness, Raynaud phenomenon, digital gangrene, supraclavicular bruit or mass, and stroke
  2. Venous compression: Edema and pain, thrombosis causing superficial venous dilation in the shoulder area
  3. Neurologic compression: Pain and/or paresthesia of neck, shoulder region, arm or hand, depending on the root involved with difficulty; intrinsic weakness and diminished sensation on examination
  4. Possible supraclavicular tenderness
  5. Provocative tests (Adson (Fig. E2), Wright): May reproduce pain but are of disputed usefulness

ETIOLOGY

- Congenital cervical rib or fibrous extension of cervical rib
- Abnormal scalene muscle insertion
- Drooping of shoulder girdle from generalized hypotonia or trauma
- Narrowed costoclavicular interval as a result of downward and backward pressure on shoulder (sometimes seen in individuals who carry heavy backpacks), poor posturing, pregnancy
- Acute venous thrombosis with exercise (effort thrombosis)
- Bony abnormalities of first rib
- Abnormal fibromuscular bands
- Malunion of clavicle fracture

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Carpal tunnel syndrome
- Cervical radiculopathy
- Brachial neuritis
- Ulnar nerve compression (cubital tunnel syndrome)
- Complex regional pain syndrome
- Superior sulcus tumor

WORKUP

Fig. 3 describes a diagnostic algorithm for thoracic outlet syndrome. Preliminary criteria for the clinical diagnosis of neurogenic thoracic outlet syndrome are summarized in Table 2. Except for venous or arterial pathology, no ancillary diagnostic tests are reliable for diagnostic confirmation.

IMAGING STUDIES

- Electromyography, nerve conduction velocity studies to rule out carpal tunnel syndrome, cervical radiculopathy
- Ultrasound for initial evaluation for arterial or venous thoracic outlet syndrome
- Cervical spine radiographs to rule out cervical disk disease
- Chest radiograph to rule out lung tumor
- Computed tomography (CT) for detailed anatomical relationship of vascular structure to surrounding muscles and bones
- Contrast-enhanced magnetic angiography can be very useful in assessing vessel imaging while using provocative arm positions
- Arteriography or venography (Fig. E4) can be used for dynamic studies while performing upper extremity maneuvers and also performing thrombolysis, if needed

TREATMENT

ACUTE GENERAL Rx

- Sling for pain relief
- Physical therapy modalities plus shoulder girdle–strengthening exercises
- Postural reeducation
- Nonsteroidal antiinflammatory drugs
- Muscle relaxants

CHRONIC Rx

Surgical treatment is indicated:

- After failure of physical therapy
- With complications such as thrombosis, aneurysms
- With neurologic compressions
- With sympathetic cervical rib

Surgical options:

- Thoracic outlet decompression
- Cervical rib resection
- Thoracic sympathetectomy
- Vascular repair
- Catheter-directed thrombolysis

TABLE 1 Sites and Structures Compressed in Thoracic Outlet Syndrome

Site	Description	Abnormalities	Structures Compressed
Sternal-costovertebral circle	This aperture can be narrowed by bony variations	• Cervical first rib • First rib • Long transverse process	• Subclavian artery • Subclavian vein • Brachial plexus
Scalene muscle triangle	The scalenus anterior and middle muscle insert on the first rib, creating a tunnel	Scalenus anterior and middle	• Subclavian artery • Brachial plexus
First rib, clavicular space	The neurovascular structures lie above the rib and below the clavicle	• Costoclavicular ligament • Clavicle • First rib	• Subclavian vein • Subclavian artery • Brachial plexus
Behind the pectoralis minor muscle	The neurovascular structures travel to and from the arm behind this muscle	• Pectoralis minor • Costocoracoid ligament	• Subclavian vein • Subclavian artery • Brachial plexus

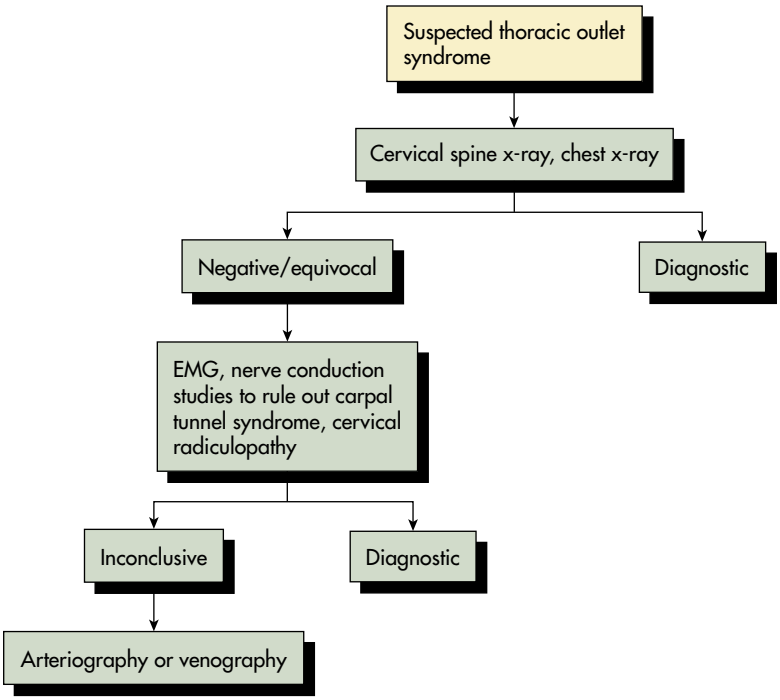

FIG. 3 Thoracic outlet syndrome. *EMG,* Electromyogram.

TABLE 2 Preliminary Criteria for the Clinical Diagnosis of Neurogenic Thoracic Outlet Syndrome

Unilateral or bilateral upper extremity symptoms that:
(1) Extend beyond the distribution of a single cervical nerve root or peripheral nerve
(2) Have been present for at least 12 wk
(3) Have not been explained satisfactorily by another condition
(4) Meet at least one criterion in at least four of the following five categories:

1. Principal symptoms	1A. Pain in the neck, upper back, shoulder, arm, or hand
	1B. Numbness; paresthesias; or weakness in the arm, hand, or digits
2. Symptom characteristics	2A. Pain, paresthesias, or weakness exacerbated with elevated arm positions
	2B. Pain, paresthesias, or weakness exacerbated by prolonged or repetitive arm or hand use or by prolonged work on a keyboard or other repetitive strain
	2C. Pain or paresthesias radiate down the arm from the supraclavicular or infraclavicular space
3. Clinical history	3A. Symptoms began after occupational, recreational, or accidental injury of the head, neck, or upper extremity, including repetitive upper extremity strain or overuse activity
	3B. Previous clavicle or first rib fracture or known cervical rib(s)
	3C. Previous cervical spine or peripheral nerve surgery without sustained improvement
	3D. Previous conservative or surgical treatment for thoracic outlet syndrome
4. Physical examination	4A. Local tenderness on palpation over scalene triangle or subcoracoid space
	4B. Arm, hand, or digit paresthesias on palpation over scalene triangle or subcoracoid space
	4C. Weak handgrip, intrinsic muscles, or digit 5 or thenar or hypothenar atrophy
5. Provocative maneuvers	5A. Positive upper limb tension test (ULTT)
	5B. Positive 1- or 3-min elevated arm stress test (EAST)

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

DISPOSITION

- Nonsurgical treatment: Often successful for patients with pain as the primary symptom
- Complications of surgical treatment include transient dysesthesia, venous injury, arterial injuries, or brachial plexus injuries.

REFERRAL

For vascular surgery consultation when venous or arterial impairment is present

PEARLS & CONSIDERATIONS

COMMENTS

- True thoracic outlet syndrome is probably an uncommon condition.
- Diagnosis is often used to describe a wide variety of clinical symptoms.
- Considerable disagreement exists regarding the frequency of this disorder.

Thoracic Outlet Syndrome (Patient Information)

AUTHOR: **Hisashi Tsukada, MD, PhD**

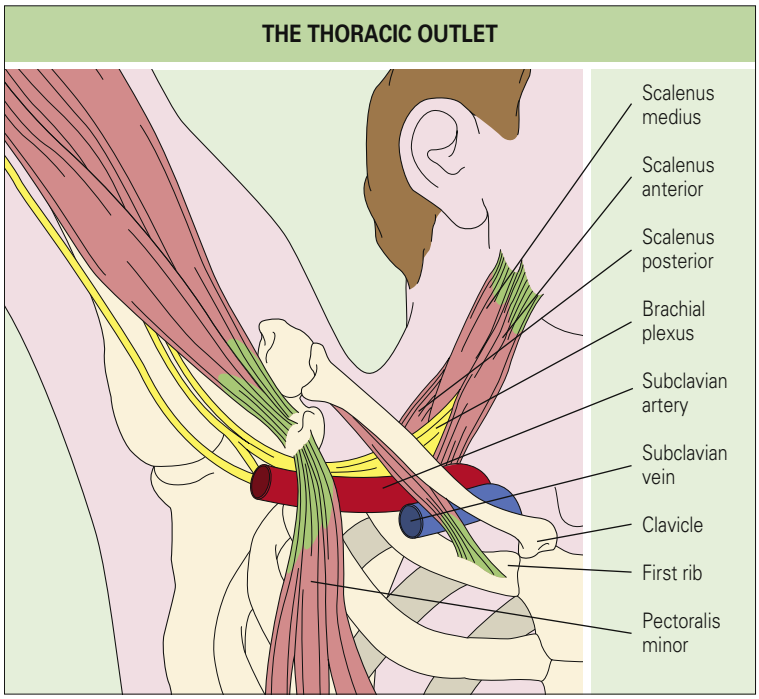

FIG. E1 The three narrow channels of the thoracic outlet include the scalene triangle, the costoclavicular passage, and the pectoralis minor attachment at the coracoid process. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

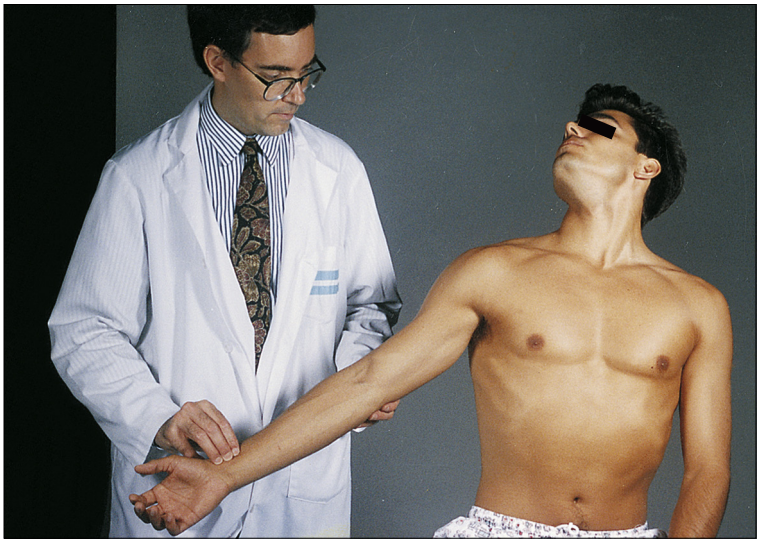

FIG. E2 The Adson maneuver. The patient inhales deeply, extends the neck fully, and turns the head to the side being examined. This tests for compression in the scalene triangle; the test result is positive if the radial pulse diminishes and the patient's symptoms are reproduced. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

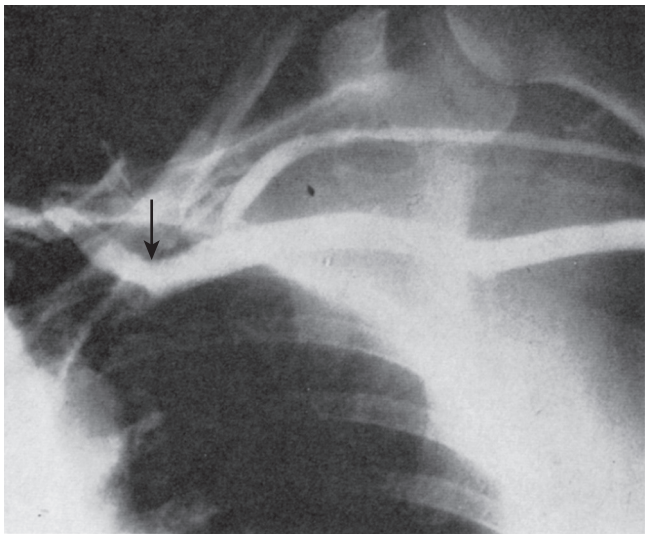

FIG. E4 Phlebogram showing total occlusion *(arrow)* with minimal collateral circulation of the left subclavian vein resulting from thoracic outlet compression. At operation, no thrombus was present in the vein, and obstruction was relieved by removing the first rib. (From Sellke FW et al: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

Thromboangiitis obliterans (TAO), also known as Buerger disease, is an uncommon, segmental nonatherosclerotic, inflammatory vascular disease that most commonly affects small- and medium-sized arteries, veins, and nerves of the extremities. It is strongly associated with tobacco use and is characterized by the segmental presence of highly cellular and inflammatory thrombotic occlusions with relative sparing of the vascular wall. In contrast to other forms of vasculitis, TAO does not involve disruption of the intima or the media.

SYNONYMS

Buerger disease
TAO
Presenile gangrene

ICD-10CM CODE
I73.1 Thromboangiitis obliterans (Buerger's disease)

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Although TAO has been observed worldwide, it is most prevalent in the Mediterranean, Asia, the Middle East, and Eastern Europe, where the rate of tobacco use is higher. Overall prevalence is declining.

- In the U.S., the prevalence is 12.6 in 100,000.
- Among patients with peripheral artery disease, the prevalence of TAO has been reported to range as low as 0.5% to 5.6% in Western Europe to as high as 45% to 63% in India and 16% to 66% in Korea and Japan, although there are reports of changing demography including an increase in the number of non-Asians affected.

PREDOMINANT SEX AND AGE: TAO affects predominantly males (70% to 91%), typically between the ages of 25 and 45, with one report suggesting a median age at diagnosis of 38.5. However, recent studies suggest an increasing incidence among women (11% to 23%), likely reflecting increasing use of cigarettes among women.

RISK FACTORS:

- Tobacco use
- Male sex
- Asian ethnicity
- Chronic periodontal infections have been linked; however, a causative association has not been firmly established

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typical presentation: Asian males between 25 and 45 with a strong history of tobacco use.
- Signs of digital ischemia on physical exam:
  1. Prolonged capillary refill with dependent rubor
  2. Absent or diminished distal pulses
  3. Digital skin discoloration/cyanosis, Raynaud phenomenon
  4. Digital ulcerations
  5. Gangrene
  6. Superficial thrombophlebitis in a migratory pattern of tender nodules (helps distinguish TAO from other vasculitis)
- Common symptoms:
  1. Rest pain
  2. Paresthesias
  3. Claudication with involvement of proximal arteries including that of the foot, arch, or calf
- The predominance of distal limb involvement helps distinguish TAO from peripheral artery disease. One case series reported 46% of TAO patients with only lower-extremity ulcers, 28% with only upper-extremity ulcers, and 25% with involvement of both upper and lower extremities.
- On rare occasions, it has been reported that with advancement of disease, the proximal arteries can become involved, and more dramatic presentations can develop involving the visceral, cerebral, renal, ocular, and coronary arteries, including case reports of coronary artery dissection, acute kidney injury, papillophlebitis.

ETIOLOGY

- The etiology of TAO remains unclear; however, a multifactorial mechanism has been proposed that involves a combination of genetic susceptibility, tobacco exposure, prothrombotic factors, and autoimmune response.
- Impaired endothelium-dependent vasorelaxation in the peripheral vasculature of patients has been noted.
- There is a growing body of evidence to suggest that alterations in the autoimmune response play a role in disease progression. Cell-mediated sensitivity to types I and III collagen are detected with increased frequency in patients with thromboangiitis obliterans. The immunology of TAO is complex, with multiple pathways implicated. It is a matter of current study.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Atherosclerosis
- Acquired or inherited hypercoagulability
- Thromboembolic disease
- Vasculitides including polyarteritis nodosa
- Autoimmune and connective tissue diseases, i.e., SLE, CREST, and scleroderma
- Diabetic angiopathy
- Acrocyanosis
- Traumatic arterial thrombosis
- Occupational (chronic vibration syndrome, hypothenar hammer syndrome)
- Ergotamine, lead, or drug poisoning
- Disseminated intravascular coagulation
- Marijuana-associated peripheral arteriopathy (subject of a case report)

WORKUP

Diagnostic evaluation for thromboangiitis obliterans is summarized in Table E1. There are no universally accepted diagnostic criteria, but several have been proposed over the yrs by Papa, Mills, Olin, and Shionoya. Biopsy would provide a definitive diagnosis but is rarely needed, and a clinical diagnosis can be established in patients who meet the following criteria:

- History of smoking or tobacco use
- Onset before the age of 50 yr
- Evidence of distal extremity ischemia
- Typical angiographic findings of TAO (sensitive but not specific)
- Absence of atherosclerotic risk factors other than smoking

LABORATORY TESTS

- There are no specific tests to diagnose TAO. The primary goal of laboratory testing is to exclude alternative diagnoses. The following labs are usually normal or negative in patients with TAO and should be obtained:
  1. Inflammatory markers: ESR and CRP
  2. Autoimmune panel: ANA, RF, anti-centromere and anti-SCL70
  3. Hypercoagulability workup: Lupus anticoagulant, anticardiolipin antibody, proteins C and S, antithrombin III, prothrombin gene mutation, and factor V Leiden
  4. Toxicology screen: Cocaine, amphetamine, cannabis
  5. Complete blood count and metabolic panel
- If there is clinical suspicion for the disease but the patient denies use of tobacco, a urine

TABLE E1 Diagnostic Evaluation for Thromboangiitis Obliterans

Clinical	Laboratory	Imaging and Physiologic Testing
Digit ulcers	Complete blood cell count	Echocardiography
Gangrene	Liver function tests	Arteriography
Venous nodules or cords	Serum creatinine	Segmental pressures
Sensory deficits	Fasting blood glucose	Arterial waveform analysis
Allen test	Sedimentation rate	
Ankle-brachial index	Antinuclear antibody	
	Rheumatoid factor	
	Complement	
	CREST serology	
	Scleroderma serology	
	Hypercoagulability	
	Toxicology screen	

CREST, Calcinosis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasia.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

BOX E1 Angiographic Findings in Thromboangiitis Obliterans (Buerger Disease)

- Involvement of small- and medium-sized vessels; Palmar, plantar, tibial, peroneal, radial, and ulnar arteries; and digital arteries of fingers and toes
- Normal extremity arteries proximal to the popliteal and distal brachial levels
- Absence of proximal atherosclerosis and vascular calcification
- No source of thrombus
- Abrupt transition from a normal, smooth proximal artery to an area of occlusion
- Symmetric and segmental arterial involvement
- Tortuous "corkscrew" collaterals are suggestive, but not pathognomonic, of Buerger disease

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

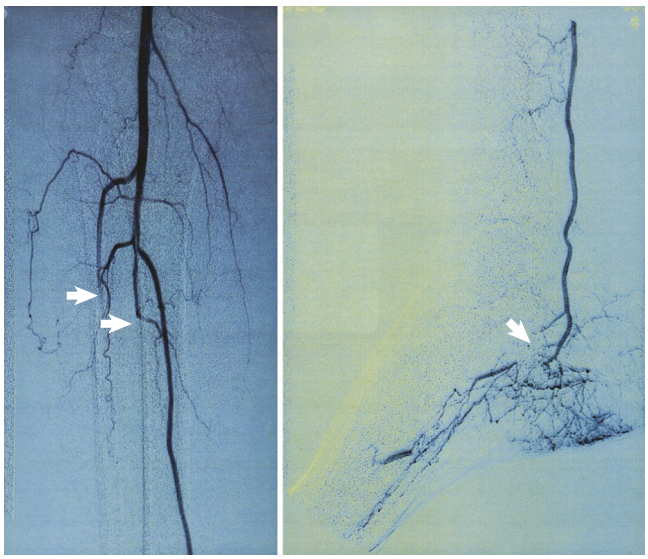

FIG. E1 Angiograms of a young woman with thromboangiitis obliterans. *Left,* Occlusion of anterior tibial and peroneal arteries *(arrows). Right,* Occlusion of distal portion of posterior tibial artery *(arrow)* with bridging collateral vessels. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

cotinine level can be ordered to confirm suspicion of recent smoking.
- Recent data has suggested the utility of a neutrophil/lymphocyte ratio in routine evaluation. Another recent study also associated TAO with elevated homocysteine levels.

NONINVASIVE VASCULAR EVALUATION

- Ankle-brachial index if lower-extremity signs or symptoms, wrist-brachial index for upper-extremity signs or symptoms with digit pressures should be performed.
- Digital plethysmography may demonstrate attenuated, flattened arterial waveforms.
- Allen test.
- Some investigative modalities are laser doppler luometry and laser speckle imaging, which have been suggested as adjuvant imaging modalities to assist with diagnosis.
- These nonspecific tests assess perfusion to distal extremities and do not distinguish TAO from other forms of peripheral vascular disease.

IMAGING STUDIES

- Noninvasive evaluation with computed tomographic angiography (CTA), magnetic resonance angiography (MRA), or duplex ultrasonography can assist.
- Echocardiography may be required to rule out thromboembolic causes.
- Angiography remains the gold standard and may be performed to define the extent of disease, to confirm the diagnosis, and potentially to deliver therapeutic interventions.
- Typical angiography findings in TAO are described in Box E1. Fig. E1 shows an angiogram of a patient with TAO (Martorell Sign: Corkscrew Collaterals, sensitive but not specific for TAO).

PATHOLOGY: Although not necessary, biopsy helps confirm diagnosis and is useful in atypical presentations.
- May show highly cellular thrombus within artery or vein in the acute phase with evidence of organization and recanalization in later stages.
- Segmental obliteration of involved vessels ("skip" lesions) with preservation of the internal elastic membrane of the vessel wall.

Rx TREATMENT

MEDICAL THERAPY

- Box E2 summarizes treatment options for thromboangiitis obliterans. Smoking cessation is the only definitive treatment for TAO. Complete abstinence may halt progression

BOX E2 Treatment Options for Thromboangiitis Obliterans

Tobacco cessation*

Medical
- Prostacyclin and its analogues
- Aspirin
- Selective low-dose intraarterial streptokinase
- Bosentan, a dual endothelin-1 receptor antagonist
- Cyclophosphamide
- Guanethidine sympathetic blocks
- Serotonin blockers
- Sarpogrelate
- Intramuscular injections of vascular endothelial growth factor
- Phosphodiesterase type 5 (PDE5) inhibitors
- Omalizumab

Endovascular Therapies
- Extended angioplasty of each tibial and foot artery obstruction

Surgical Treatment
- Sympathectomy
- Arterial reconstruction
- Omental transfer
- Kirschner wire in medullary canal of tibia

Experimental Therapies
- Intramuscular injection of vascular endothelial growth factor
- Autologous whole bone marrow stem cell transplantation by fenestration
- Immunoadsorption
- Beperminogene perplasmid use

Interventional therapy
- Pneumatic compression has been used to augment perfusion to the lower extremities in patients with severe claudication or critical limb ischemia who are not revascularization candidates.
- Endovascular treatment with extended angioplasty at the tibial and foot arteries remains an option for patients with TAO and critical limb ischemia. This modality has prevented major amputations, with studies reporting a technical success rate of 66.7% to 91%, a limb salvage rate of 92% to 100%, and sustained clinical improvement in 84.2% of patients.
- Surgical revascularization usually is not feasible due to the distal and diffuse nature of the disease. However, bypass may be considered in patients with more proximal disease or suitable distal target vessels.
- Use of a spinal cord stimulator has been shown to improve regional perfusion and symptoms. It relieves pain through several mechanisms, including preventing transmission of painful stimuli through the corresponding dermatomes, stimulating the production of inhibitory neurotransmitters, and inhibiting sympathetic vasoconstriction, which improves peripheral microcirculation.
- Sympathectomy may be considered for patients with refractory pain and digital ischemia (Box E3).

*Only known, proven, established, and effective therapy.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

BOX E3 Treatment Options in Thromboangiitis Obliterans (Buerger Disease)

- Cessation of tobacco products
- Local wound care
- Arterial reconstruction with vein graft
- Prostaglandin analog iloprost or treprostinil sodium
- Cilostazol
- Hyperbaric oxygen therapy
- Calcium channel blockers (e.g., amlodipine or nifedipine for vasospasm)
- Intermittent pneumatic compression pump
- Implantable spinal cord stimulator
- Therapeutic angiogenesis
- Amputation

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

of disease and prevent flares. Use of nicotine replacement should be avoided due to risk of keeping disease active, but use of other smoking-cessation pharmacotherapy (e.g., bupropion or varenicline) is reasonable. The hazards of continued smoking in patients with TAO seem to be independent of factors such as number of cigarettes smoked per day.

- To date, there is no proven standard-of-care pharmacotherapy, and thus therapeutic options have been limited to prostaglandin analogs and vasodilators for palliative treatment.
  1. Iloprost, a prostaglandin analog, has been associated with reduced rest pain and greater healing of ischemic ulcers; however, it is not associated with a reduction in the amputation rate. The oral formulation has been shown to be no more effective than placebo.
  2. Vasodilators (calcium channel blockers, alpha blockers, cilostazol, sildenafil) may be helpful in symptom relief but have not been studied in prospective clinical trials.
  3. Bosentan, an endothelin receptor antagonist most commonly used in pulmonary arterial hypertension, has been used as a non-FDA approved therapy.
- There is no evidence to support the routine use of antiplatelet, anticoagulant, or thrombolytic agents; however, aspirin is routinely administered.
- Daily foot and hand hygiene will prevent ischemic ulcers, as well as avoidance of trauma, vibration, and cold.

OUTCOMES:

- Periods of exacerbation and remission are characteristic of TAO. The disease typically intensifies at the age of 30 to 40 and then abates. Patients aged 60 yr or older rarely have recurrence of symptoms.
- The risk of major amputation was 11% at 5 yr, 21% at 10 yr, and 23% at 20 yr. Risk of amputation was eliminated by 8 yr after smoking cessation. Multiple amputations and progressive disability cause decline in quality of life.
- One long-term followup of 224 patients demonstrated that in a mean of 5.7 yr, vascular events occurred in 58.9% of patients, amputation in 21.4%, and death in 1.4%.
- Patients with TOA are prone to premature atherosclerosis, and thus the incidence of peripheral and coronary atherosclerosis is higher in this patient population.

REFERRAL

Smoking cessation counseling, rheumatology consultation, and vascular surgery consultation are recommended for any young smokers with claudication and ischemic ulcers.

PEARLS & CONSIDERATIONS

- The pathogenesis of the disease is poorly understood, but tobacco use plays a key role.
- A multifactorial mechanism has been proposed that involves a combination of genetic susceptibility, tobacco exposure, prothrombotic factors, and autoimmune response.
- The diagnosis is predominantly clinical, and there are no universally accepted diagnostic criteria. Biopsy can confirm diagnosis but is rarely needed.
- Discontinuation of tobacco use is the only known definitive therapy for TAO.

PATIENT & FAMILY EDUCATION

Patients with TAO must be warned about tobacco use and secondhand passive smoke. Information for patients can be obtained from the following organizations:

- Vascular Disease Foundation (www.vdf.org)
- Mayo Foundation for Medical Education and Research (www.mayoclinic.com)

BASIC INFORMATION

DEFINITION

Thrombocytosis is defined by an elevated platelet count (>450,000/ml) in peripheral blood. It is caused by overproduction of platelets (reactive thrombocytosis) or clonal expansion of megakaryocytes (clonal thrombocytosis). Reactive thrombocytosis is driven by excessive cytokines induced by various stimuli, such as trauma or inflammation. Clonal thrombocytosis is defined as chronic myeloproliferative neoplasms (MPNs), of which four subgroups are well characterized: chronic myelogenous leukemia (CML), polycythemia vera (PV), primary myelofibrosis (PMF), and essential thrombocythemia (ET). In addition, platelet count can be spuriously elevated in some conditions (see "Differential Diagnosis"). Extreme thrombocytosis is defined as platelet count >1 million/ml.

SYNONYMS

Thrombocythemia
Essential thrombocythemia
ET

ICD-10CM CODES

D47.3	Essential (hemorrhagic) thrombocythemia
D75.89	Other specified diseases of blood and blood-forming organs
D75.9	Disease of blood and blood-forming organs, unspecified
D77	Other disorders of blood and blood-forming organs in diseases classified elsewhere

EPIDEMIOLOGY & DEMOGRAPHICS

Reactive thrombocytosis is much more frequent than clonal thrombocytosis (70% vs. 22% in one series).

Epidemiology for essential thrombocythemia:
INCIDENCE: 1.2 to 3.0 per 100,000 population/yr
PREVALENCE: Estimated as 24 cases/100,000 population
PREDOMINANT SEX AND AGE: The median age at diagnosis is 58 yr. Female:male ratio is 2:1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Regardless of the cause, a high platelet count may be associated with vasomotor symptoms such as headache, visual disturbances, dizziness, atypical chest pain, acral dysesthesia, and erythromelalgia.
- Thrombotic and bleeding complications can occur.
- Symptoms and complications are much more likely to occur in association with clonal thrombocytosis than reactive thrombocytosis.
- The degree of thrombocytosis does not predict the likelihood of clonal thrombocytosis and does not generally correlate to the risk of thrombosis.
- Splenomegaly is common with MPNs.
- Coexistent leukocytosis and erythrocytosis are common with CML and PV.
- Disease transformation from ET to PV, PMF, and acute myeloid leukemia (AML) is uncommon. In patients with ET, the 20-yr rate of leukemic transformation is estimated at 5%.

ETIOLOGY

- Essential thrombocytosis, a myeloproliferative neoplasm, is a clonal disorder of a multipotent hematopoietic progenitor cell.
- Abnormality in JAK2-STAT pathway (including *JAK2, CALR*, and *MPL* gene mutations) may play a role in pathogenesis of MPN.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Spurious thrombocytosis:
  1. Mixed cryoglobulinemia—precipitated cryoglobulin particles are counted as platelets by automatic counters; generally occurs at low temperatures.
  2. Circulating cytoplasmic fragments miscounted as platelets—seen mainly in patients with leukemia, lymphoma, severe hemolysis, or burns
- Reactive thrombocytosis:
  1. Benign hematologic disorders
  2. Acute hemorrhage, iron deficiency anemia, hemolytic anemia
  3. Chronic infection, such as tuberculosis
  4. Acute and chronic inflammatory disorders
  5. Rheumatologic disorders
  6. Inflammatory bowel disease
  7. Celiac disease
  8. Functional and surgical asplenia
  9. Tissue damage
  10. Trauma, thermal burn
  11. Myocardial infarction
  12. Acute pancreatitis
  13. Recent surgery
  14. Renal failure, nephrotic syndrome
  15. Exercise
  16. Medications, such as vincristine, epinephrine
- Clonal thrombocytosis:
  1. CML
  2. PV
  3. PMF
  4. Myelodysplastic syndrome (5q-syndrome)
  5. AML with inv(3), t(3;3)
  6. Essential thrombocytosis (Box 1)

WORKUP

- Comprehensive history and physical examination to exclude many of the common causes of reactive thrombocytosis: History and physical examination suggestive of acute blood loss, iron deficiency, acute or chronic infection/inflammation, medication use, asplenia, malignancy, and trauma should be evaluated. Fig. E1 describes a diagnostic algorithm for thrombocytosis. The diagnosis of ET requires platelet counts >450 × 10^3/ml on two separate occasions >4 weeks apart, absence of Philadelphia chromosome, and exclusion of secondary causes of thrombocytosis.
- Repeat CBC with peripheral blood smear and bone marrow biopsy (Figs. E2 and E3) to exclude spurious thrombocytosis.

LABORATORY TESTS

- CBC with peripheral blood smear: Howell-Jolly bodies and target cells are present in patients with asplenia; nucleated RBC, teardrop RBC and WBC precursors in patients with PMF.
- Serum ferritin level: Low ferritin level suggests iron deficiency.

BOX 1 World Health Organization Diagnostic Criteria for Essential Thrombocythemia

Diagnosis requires that all of the following criteria be met:
- Sustained platelet count ≥450 × 10^9/L*
- Bone marrow biopsy specimen showing proliferation mainly of the megakaryocytic lineage, with increased numbers of enlarged, mature megakaryocytes; no significant increase or left shift of neutrophil granulopoiesis or erythropoiesis
- Failure to meet the WHO criteria for polycythemia vera,† primary myelofibrosis,‡ BCR-ABL1–positive chronic myelogenous leukemia,§ myelodysplastic syndrome,¶ or other myeloid neoplasms
- Demonstration of *JAK2 V617F* or other clonal marker; or, in the absence of *JAK2 V617F*, no evidence of reactive thrombocytosis¶

WHO, World Health Organization.
*Sustained during the workup process.
†Requires the failure of iron replacement therapy to increase the hemoglobin level to the polycythemia vera range in the presence of decreased serum ferritin. Exclusion of polycythemia vera is based on hemoglobin and hematocrit levels; red cell mass measurement is not required.
‡Requires the absence of relevant reticulin fibrosis, collagen fibrosis, peripheral blood leukoerythroblastosis, or markedly hypercellular marrow accompanied by megakaryocyte morphology typical for primary myelofibrosis—small to large megakaryocytes with an aberrant nuclear-to-cytoplasmic ratio and hyperchromatic, bulbous, or irregularly folded nuclei and dense clustering.
§Requires the absence of BCR-ABL1.
¶Requires the absence of dyserythropoiesis and dysgranulopoiesis.
¶Causes of reactive thrombocytosis include iron deficiency, splenectomy, surgery, infection, inflammation, connective tissue disease, metastatic cancer, and lymphoproliferative disorders.
From Swerdlow SH et al (eds): *WHO classification of tumours of haematopoietic and lymphoid tissues,* Lyon, France, 2008, IARC Press.

- Serum C-reactive protein (CRP), ESR, and plasma fibrinogen: Nonspecific markers of infection or inflammation.
- Philadelphia chromosome or BCR-ABL rearrangement: Positive in CML.
- Serum erythropoietin assay: Low to normal in PV and ET.
- *JAK2* mutation analysis: PV and ET; *JAK2* mutation is found in 95% to 99% of patient with PV, in 40% to 60% of patients with PMF, and in about 50% to 55% of patients with ET.
- *MPL* and *CALR* mutation analysis: Frequency is reported as 4% and 15% to 36%, respectively, in ET:
  1. These mutations are associated with differences in prognosis and risk of thrombosis.
  2. *JAK2, CALR,* and *MPL* mutations are mutually exclusive. They are not confined to a particular myeloproliferative neoplasm, and their absence does not exclude any of the MPNs.
  3. About 17% of patients with ET will be negative for *JAK2, CALR,* and *MPL* mutations.
- Bone marrow chromosome analysis: 5q- syndrome and other myelodysplastic syndrome, CML.
- Bone marrow exam in ET may show clusters of abnormal megakaryocytes and increased reticulin fibrosis (see Fig. E3).

Rx TREATMENT

No therapies are known to alter survival or leukemic transformation in ET. Reactive thrombocytosis has been rarely associated with thrombosis or bleeding and generally does not require specific therapy.

ACUTE GENERAL Rx

- Vasomotor symptoms easily manageable with low-dose aspirin (<100 mg/day).
- Bleeding:
  1. Discontinue any platelet antiaggregating agent, such as aspirin or nonsteroidal antiinflammatory agents.
  2. Evaluate for disseminated intravascular coagulopathy and coagulation factor deficiency. Acquired factor V deficiency is occasionally present in association with clonal thrombocytosis. In that case, treat with fresh frozen plasma infusion.
  3. In case of extreme thrombocytosis (platelet count generally >1,000,000/uL [1000×10^9/L]), acquired von Willebrand disease may occur. Immediate definitive therapy with a platelet-lowering agent is essential in this instance. Platelet pheresis should be reserved for cases of acute thrombosis or bleeding.
- Thrombosis:
  1. Arterial or venous thrombosis occurs in 20% to 30% of patients.
  2. If the platelet count is >800,000/ml, platelet apheresis coupled with a platelet-lowering agent should be considered with the goal of platelet count <400,000/mm^3.
  3. Anticoagulant therapy for 3 months to indefinite based on the presence or absence of additional thrombophilic defects.

CHRONIC Rx

Treatment strategies for ET are based on the presence or absence of risk factors for thrombosis. Smoking cessation and obesity management should be discussed with all patients with ET. In low-risk patients (age <60 yr, no history of thrombosis or hemorrhage, platelet count <1 million/ml), observation may be adequate. Treatment with low-dose aspirin is indicated in low-risk patients with vasomotor symptoms or with other indications for aspirin use. The cytoreductive therapy along with low-dose aspirin therapy is indicated in high-risk patients (age >60 yr and/or with previous history of thrombosis) regardless of vasomotor symptoms.

- Low-dose aspirin (81 mg/day) may be safe and effective in preventing vascular events. It is also effective in preventing recurrent vascular events in high-risk patients and in treating the vasomotor symptoms.
- Cytoreductive therapy (Table 1):
  1. First-line therapies typically include hydroxyurea and interferon in the majority of cases. Anagrelide and interferon (if not used previously) generally are considered second line.
  2. Hydroxyurea (HU) versus anagrelide: HU plus aspirin is suggested to be safer and more effective than anagrelide plus aspirin in regard to thrombosis, bleeding, and transformation to PMF at 5 yr in a randomized trial. Monitor liver function tests and the degree of neutropenia or anemia with HU therapy.
  3. The incidence of leukemic conversion in patients with ET treated with HU alone is reported as <1%. Interferon alpha may be effective for controlling platelet count in patients failing treatment with HU.

TABLE 1 Choice of Drugs for Treatment of Patients with High-Risk Essential Thrombocythemia

Age (yr)	Treatment of Choice	Second Line
<50	Interferon	Anagrelide Hydroxyurea
50-75	Hydroxyurea	Interferon Anagrelide
>75	Hydroxyurea	Anagrelide

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

DISPOSITION

- Although long survival is expected in patients with ET, it is inferior to the sex- and age-matched U.S. population.
- An International Prognostic Score for Essential Thrombocythemia (IPSET) was proposed by International Working Group on Myelofibrosis Research and Treatment based on age, WBC count, and history of thromboembolism at diagnosis.

REFERRAL

Refer to hematologist/oncologist when platelet count is consistently elevated >450,000/mm^3 without causes for reactive thrombocytosis.

PEARLS & CONSIDERATION

COMMENTS

- Some patients with clinically apparent ET have Philadelphia chromosome or BCR-ABL rearrangement, even in the absence of other features of CML. It is suggested that it should be tested in all ET patients due to its potential therapeutic implications.
- The risk of bleeding with aspirin use in patients with ET paradoxically increases when the platelet count is >1 million/ml, likely due to acquired von Willebrand disease.

PATIENT & FAMILY EDUCATION

Smoking cessation is encouraged in both patients with ET and reactive thrombocytosis.

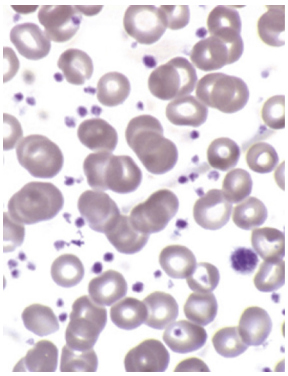

FIG. E2 Essential thrombocythemia (ET): Peripheral blood smear. The peripheral blood smear in ET shows a marked thrombocytosis with anisocytosis (varying sizes) of the platelets. (From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Churchill Livingstone.)

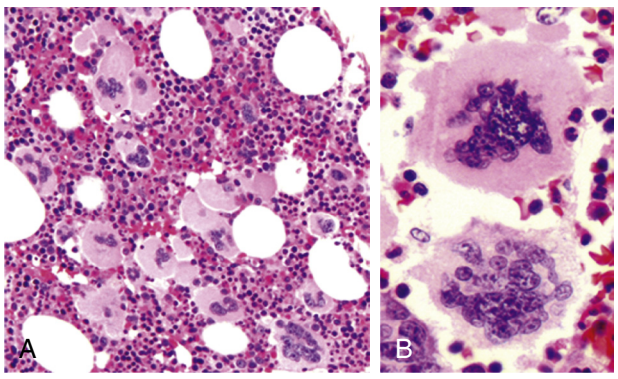

FIG. E3 Essential thrombocytosis: Bone marrow biopsy. The bone marrow **(A)** is hypercellular and exhibits a marked proliferation of large and giant megakaryocytes in loose clusters with other hematopoietic elements in the background. The large megakaryocytes **(B)** tend to be extensively lobulated. (From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Churchill Livingstone.)

Thrombophlebitis, Superficial Venous PTG

BASIC INFORMATION

DEFINITION

Superficial venous thrombophlebitis (SVT) is an inflammation of a vein with subsequent secondary thrombus formation. SVT most frequently involves superficial veins of the leg, but any superficial vein can be affected. SVT has been reported to occur in 125,000 people in the U.S. per yr; however, the actual incidence is likely far greater. SVT is not always a benign condition. SVT should be regarded as the superficial venous manifestation of a systemic process known as venous thromboembolism (DVT, PE).

SYNONYMS

SVT
Superficial phlebitis
Superficial suppurative thrombophlebitis
Suppurative thrombophlebitis

ICD-10CM CODES

I80.00	Phlebitis and thrombophlebitis of superficial vessels of unspecified lower extremity
I80.8	Phlebitis and thrombophlebitis of other sites
I80.9	Phlebitis and thrombophlebitis of unspecified site

EPIDEMIOLOGY & DEMOGRAPHICS

- Approximately 30% to 45% of patients diagnosed with SVT are men with an average age of 54 yr.
- Approximately 55% to 70% of patients diagnosed with SVT are women with an average age of 58 yr.
- The overall recurrence of SVT is 18% over an average observation period of 15 mo, equally involving varicose and nonvaricose veins.
- The lifetime incidence of SVT in those with untreated varicose veins has been estimated at 25% to 50%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Subcutaneous vein is palpable as a tender cord or "wormlike" mass with increased warmth and erythema.
- Induration, redness, and tenderness are localized along the course of the vein. This linear appearance rather than circular appearance is useful to distinguish thrombophlebitis from other conditions (cellulitis, erythema nodosum).
- There is some swelling of the overlying skin and subcutaneous tissue but without generalized edema of the limb.
- Low-grade fever may be present.

ETIOLOGY

- In the lower extremity, 70% of SVT occurs in patients with varicose veins, with the great saphenous vein being most commonly involved (60% to 80%)
- Intravenous catheters and infusion of caustic drugs are the most common cause of upper-extremity SVT
- Malignancy
- Pregnancy/puerperium
- Hypercoagulable states
- Previous DVT/SVT
- OCP (oral contraceptive pill)/HRT (hormone replacement therapy)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphangitis
- Cellulitis
- Erythema nodosum
- Panniculitis
- Acute lipodermatosclerosis

WORKUP

The clinical investigation includes not only the local findings but also the presence of varicose veins with or without the stigmata of chronic venous insufficiency. Today, duplex ultrasound is the most important additional diagnostic tool.

IMAGING STUDIES

- Duplex ultrasound offers the advantage of being inexpensive, noninvasive, and repeatable for follow-up examination.
- Ultrasonography confirms the diagnosis, shows the location of the thrombus and its location regarding the saphenofemoral and/or saphenopopliteal junctions.
- Ultrasound examination of patients with SVT has revealed that a concomitant DVT can exist in 15% to 20%.
- In up to 25% of these patients, the DVT may not be contiguous with the SVT and may be found in the contralateral leg.
- Therefore, bilateral duplex exam is recommended in all cases of SVT that involve the main trunk of the great saphenous vein (GSV) or small saphenous vein (SSV).

TREATMENT

NONPHARMACOLOGIC THERAPY

- Warm, moist compresses
- Do not restrict activity. Immediate mobilization with walking exercises

ACUTE GENERAL Rx

- Treatment guidelines for SVT are not well established because of the lack of controlled clinical trials. In general, the primary goal of management should be to prevent thrombus extension and the risk of venous thromboembolism. All other therapy is directed at patient comfort with analgesics and NSAIDs (in patients not receiving anticoagulants).
- In patients with migratory SVT, recurrent SVT, or SVT without varicose veins, the underlying condition should be investigated, and treatment directed accordingly.
- The most common cause of upper-extremity SVT is an intravenous catheter. Treatment starts with removal of the cannula and application of warm compresses. The resultant lump may persist for mos. No anticoagulant therapy is required.
- In patients with lower-extremity SVT in a varicose vein branch, control of pain with analgesics and the use of gradient compression stockings are usually sufficient. Patients are encouraged to continue their usual daily activities.
- Many investigators favor systemic anticoagulation when there is superficial thrombosis of 5 cm or more in length, the thrombus is within 1 cm of the saphenous junctions, or more than 5 cm of the saphenous trunk is involved, as shown by duplex ultrasonography. Anticoagulation is also reasonable for patients with SVT and cancer or previous DVT.
- The American College of Chest Physicians guidelines recommend anticoagulation for 45 days over no anticoagulation in patients with lower-extremity SVT within 1 cm of the saphenofemoral or saphenopopliteal junction.
- In the case of patients with varicose veins secondary to saphenous vein reflux, a catheter vein ablation procedure should be performed only after the acute SVT episode is over in order to avoid the thromboembolic complications induced by such procedures.

PEARLS & CONSIDERATIONS

SUPERFICIAL SUPPURATIVE THROMBOPHLEBITIS

- Superficial suppurative thrombophlebitis is associated with an intravenous catheter or multiple puncture sites secondary to IV drug abuse and is located primarily in the upper extremity.
- Clinical presentation is similar to that of nonsuppurative SVT but with associated fever, leukocytosis, and/or septicemia.
- Most cases of intravenous catheter sepsis are not complicated by suppurative thrombophlebitis; local IV catheter site infections occur in about 7% of cases and septicemia is found in only 1 of every 400 IV catheterizations.
- The incidence of peripheral vein suppurative thrombophlebitis is highest in patients with specific risk factors such as burns, steroids, and IV drug abuse.
- Treatment consists of antibiotics with adequate coverage of gram-negative rods and *Staphylococcus aureus,* including MRSA. Initial empirical treatment is with IV vancomycin 1 g q12h *plus* ceftriaxone 1 g IV q24h. Alternative regimen consists of daptomycin 6 mg/kg IV q 12h *plus* ceftriaxone 1 g IV q24h.

BASIC INFORMATION

DEFINITION

Thrombotic thrombocytopenic purpura (TTP) is a rare autoimmune disorder characterized by thrombocytopenia and microangiopathic hemolytic anemia that can be associated commonly with other hallmarks such as neurologic impairment, renal dysfunction, and fever. The laboratory hallmark of TTP is a severe deficiency of the *ADAMTS13* factor (activity <10%).

SYNONYMS

TTP
Upshaw-Schulman Syndrome

ICD-10CM CODE
M31.1 Thrombotic microangiopathy

EPIDEMIOLOGY & DEMOGRAPHICS

- About 90% of new TTP cases are seen in adults (mostly females between 18 and 50 yr).
- The incidence of new TTP is 3 to 11 cases per million population per yr. The prevalence is ~10 cases per million population.
- There is increased incidence in HIV/AIDS and during pregnancy.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The disease often begins as a flulike illness ultimately followed by clinical and laboratory abnormalities.
- Most patients present with nonspecific constitutional symptoms (weakness, nausea, abdominal pain, vomiting).
- Purpura (secondary to thrombocytopenia).
- Jaundice, pallor (from hemolysis).
- Mucosal bleeding.
- Fever.
- Fluctuating levels of consciousness (caused by thrombotic occlusion of the cerebral vessels). However, one third of patients have no neurologic abnormalities.
- Renal failure and neurologic events are usually end-stage features.

ETIOLOGY

- Acquired TTP is an autoimmune disorder caused by autoantibody inhibition of ADAMTS13 activity. Hereditary TTP (also called Upshaw-Schulman syndrome) is caused by homozygous or compound heterozygous *ADAMTS13* mutations (Table 1).
- Many drugs, including clopidogrel, ticlopidine, penicillin, antineoplastic agents (gemcitabine, mitomycin C), calcineurin inhibitors (cyclosporine), oral contraceptives, and quinine, have been associated with TTP.
- Other precipitating causes include infectious agents, pregnancy, malignancies, allogeneic stem cell transplantation, and neurologic disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

It is challenging to differentiate TTP from other thrombotic microangiopathies given the significant overlap in clinical presentation, but this distinction is critical in selecting an appropriate therapy for patients.

- Disseminated intravascular coagulation (DIC)
- Malignant hypertension
- Vasculitis
- Eclampsia or preeclampsia
- Hemolytic-uremic syndrome (HUS) and atypical HUS
- Gastroenteritis as a result of a serotoxin-producing serotype of *Escherichia coli*

WORKUP

A comprehensive history, physical examination, and laboratory evaluation usually confirm the diagnosis (Fig. 1).

LABORATORY TESTS

- Severe anemia and thrombocytopenia (platelet count <50,000 or >50% reduction from previous counts)
- Peripheral blood smear (Fig. E2, Fig. E3) reveals numerous red cell fragments (schistocytes)
- Elevated blood urea nitrogen and creatinine
- Evidence of hemolysis: Elevated reticulocyte count, indirect bilirubin, lactate dehydrogenase, decreased haptoglobin
- Urinalysis: Hematuria (red blood cells [RBCs] and RBC casts in urine sediment) and proteinuria
- Peripheral smear: Severely fragmented RBCs (schistocytes). More than 4% RBC fragments in the peripheral blood
- No laboratory evidence of DIC (normal fibrin degradation product, fibrinogen)
- The diagnosis of hereditary TTP requires documentation of *ADAMTS13* deficiency and an absence of *ADAMTS13* autoantibody inhibitor, and confirmation requires documentation of *ADAMTS13* mutations. Diagnostic criteria for acquired TTP are the presence of microangiopathic hemolytic anemia and thrombocytopenia without another apparent cause. An *ADAMTS13* level indicating less than 10% of normal activity supports the clinical diagnosis of acquired TTP while moderately decreased levels of >20% suggest the presence of other diagnoses.

TREATMENT

ACUTE GENERAL Rx

- Discontinue potential offending agents. Initiate *ADAMTS13* replacement by plasma infusion in patients with hereditary TTP.
- Current therapy for TTP is built on two complementary pillars: therapeutic plasma exchange (TPE) and immunosuppression.
- Daily TPE with replacement of 1.0 to 1.5 times the predicted plasma volume of the patient is standard therapy for TTP. TPE should be continued for a minimum of 2 days after the platelet count returns to normal (>150,000 cells/m^3).
- High-dose plasma infusion (25 ml/kg/day) may be useful only if TPE cannot be promptly started and for patients with very severe or refractory disease between plasma exchange sessions. High-dose plasma infusions can cause volume overload in patients with renal insufficiency.
- Patients with hereditary TTP who experience severe plasma allergic reactions have been effectively treated with plasma-derived factor VIII concentrate that contains *ADAMTS13*.
- Immunosuppression with the use of corticosteroids (prednisone 1 to 2 mg/kg/day) typically is administered concomitantly with TPE for a period of 3 to 4 wk.
- The monoclonal anti-CD20 antibody rituximab has been traditionally used for treatment of suboptimally responsive TTP and results in remissions in the majority of patients. Frontline use of rituximab results in shorter hospitalization with fewer relapses but is likely resulting in overtreatment in many cases.

TABLE 1 Etiology, Epidemiology, and Pathogenesis of TTP, HUS, and ADAMTS13–Related Parameters

	Congenital TTP	Acquired TTP	HUS
Etiology	*ADAMTS13* mutation	Antibody to *ADAMTS13,* endothelial cell activation	*Escherichia coli* or other microorganisms
Epidemiology	5-10 cases per yr per million	≤1 case per yr per million	1-5 cases per yr per million, mainly in children
Pathogenesis	Defective cleavage of vWF multimers, massive secretion of ultra-large vWF multimers, increased platelet deposition under shear condition, occlusion of blood vessels in microcirculation		Intoxication with Shiga-like toxin, damage of endothelial cells, enterohemorrhagic colitis, renal disorder
ADAMTS13 antigen	Very low or absent	Low or variable	Normal or moderately decreased
ADAMTS13 activity	≤5%-10%	≤5%-10% or variable	30%-100%
Inhibitor against ADAMTS13	No	Mostly yes	No

ADAMTS13, A disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13; *HUS,* hemolytic uremic syndrome; *TTS,* thrombotic thrombocytopenic purpura; *vWF,* von Willebrand factor.
From McPherson RA, Pincus MR: *Henry's clinical diagnosis and management by laboratory methods,* ed 23, Philadelphia, 2017, Elsevier.

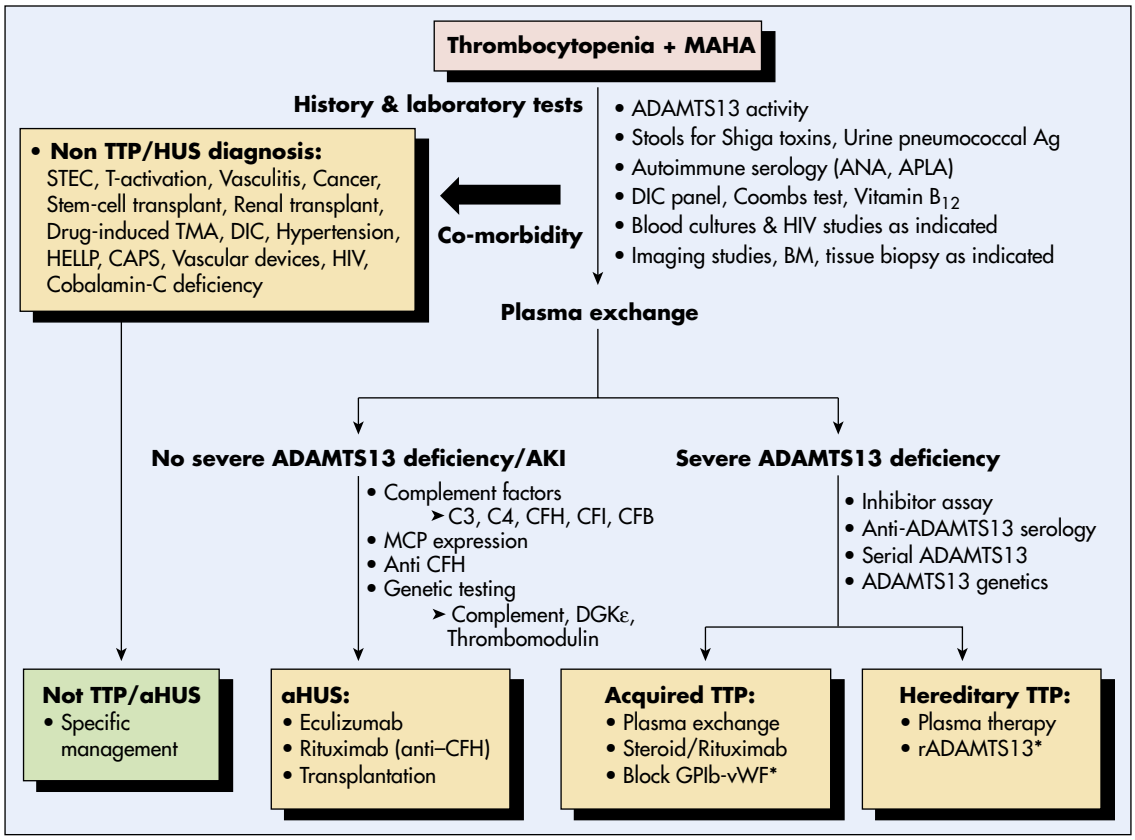

FIG. 1 An approach to diagnosis and management of thrombotic microangiopathies. *ADAMTS13,* A disintegrin and metalloproteinase with thrombospondin type 1 motifs, member 13; *Ag,* antigen; *aHUS,* atypical hemolytic uremic syndrome; *AKI,* acute kidney injury; *ANA,* antinuclear antibody; *APLA,* antiphospholipid antibodies; *BM,* bone marrow; *CAPS,* catastrophic antiphospholipid syndrome; *CFB,* complement factor B; *CFH,* complement factor H; *CFI,* complement factor I; *DGKE,* diacyl glycerol kinase ε; *DIC,* disseminated intravascular coagulation; *GP,* glycoprotein; *HELLP,* hemolysis, elevated liver enzymes, and low platelet count; *HIV,* human immunodeficiency virus; *HUS,* hemolytic uremic syndrome; *MAHA,* macroangiopathic hemolytic anemia; *MCP,* membrane cofactor protein; *rADAMTS13,* recombinant ADAMTS13; *STEC,* Shiga toxin-producing *E. coli*; *TMA,* thrombotic microangiopathy; *TTP,* thrombotic thrombocytopenic purpura; *vWF,* von Willebrand factor. *Bullet points* are diagnoses or therapies. *Indicates therapies under investigation. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

- Caplacizumab, an anti–von Willebrand factor humanized, bivalent, variable-domain-only immunoglobulin fragment, inhibits interaction between von Willebrand factor multimers and platelets. In a randomized trial, treatment with caplacizumab and plasma exchange was associated with faster normalization of the platelet count and lower incidence of a composite of TTP-related death, recurrence of TTP, or a thromboembolic event during the treatment period than placebo.
- Platelet transfusions are contraindicated except in severely thrombocytopenic patients with documented bleeding or those who are facing surgery or other invasive procedures in the setting of severe thrombocytopenia.
- Use of antiplatelet agents (acetylsalicylic acid, dipyridamole) is controversial.
- Splenectomy is performed in refractory cases.
- Dialysis is rarely required.

CHRONIC Rx

- Relapsing TTP may be initially retreated with TPE.
- TTP unresponsive to conventional therapy is usually effectively treated with rituximab and occasionally with chemotherapy agents (vincristine, cyclophosphamide).
- Splenectomy done while patients are in remission has been used historically to decrease the frequency of relapses.

DISPOSITION

- Survival of patients with TTP currently exceeds 80% with TPE.
- Relapse occurs in 20% to 40% of patients who have achieved initial remission.

PEARLS & CONSIDERATIONS

COMMENTS

- TTP should be considered in pregnant women with vague neurologic, gastrointestinal, or renal symptoms in either the obstetric triage or emergency department areas.
- TTP is fatal in 90% of patients without therapy.
- Case reports have suggested a benefit of the proteasome inhibitor bortezomib, possibly due to elimination of the autoreactive plasma cells producing anti-ADAMTS13 antibodies in patients who are refractory to TPE and rituximab administration.

BASIC INFORMATION

DEFINITION

Thyroid carcinoma is a primary neoplasm of the thyroid and consists of four major subtypes: papillary, follicular, anaplastic, and medullary.

SYNONYMS

Papillary carcinoma of thyroid
Follicular carcinoma of thyroid
Anaplastic carcinoma of thyroid
Medullary carcinoma of thyroid

ICD-10CM CODES

C73	Malignant neoplasm of thyroid gland
D09.3	Carcinoma in situ of thyroid and other endocrine glands
D34	Benign neoplasm of thyroid gland
D44.0	Neoplasm of uncertain behavior of thyroid gland

EPIDEMIOLOGY & DEMOGRAPHICS

- Thyroid cancer is the most common endocrine cancer, with an estimated 52,070 new cases and 2,170 deaths occurring in 2019 in the U.S.
- Incidence is 13.9 per 100,000 people in the U.S. and increasing over last 4 decades.
- Female:male ratio is 3:1.
- Median age at diagnosis: 45 to 50 yr.
- Occult thyroid cancer is identified in 20% of autopsy specimens.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Thyroid cancer is often identified incidentally. Physical exam may reveal:
  1. Presence of thyroid nodule
  2. Hoarseness and cervical lymphadenopathy
  3. Painless swelling in the region of the thyroid

ETIOLOGY

- Risk factors: Prior neck irradiation.
- Multiple endocrine neoplasia II (medullary carcinoma).
- Inherited syndromes associated with thyroid cancer are described in Table 1.
- GLP-1 receptor agonists for the treatment of type 2 DM (e.g., exenatide, albiglutide) can increase the risk of medullary thyroid carcinoma (MTC).

TABLE 1 Inherited Syndromes Associated with Thyroid Cancer

Multiple endocrine neoplasia (MEN) 2A and 2B
Isolated familial medullary thyroid cancer
Gardner syndrome
Familial adenomatous polyposis
Carney complex
Cowden syndrome
Familial nonmedullary thyroid cancer

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

- Although formerly thought to be a single entity, papillary thyroid carcinoma encompasses several tumor types that have mutually exclusive mutations. BRAF V600E accounts for 60% of these mutations.
- Pathways to the development of thyroid cancer are depicted in Fig. E1.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Multinodular goiter
- Lymphocytic thyroiditis
- Ectopic thyroid

WORKUP

The workup of thyroid carcinoma includes laboratory evaluation and diagnostic imaging. Key features of thyroid malignancies are summarized in Table 2. Diagnosis is confirmed with fine-needle aspiration or surgical biopsy. At diagnosis, the vast majority of thyroid cancers are well differentiated, with excellent prognosis. The characteristics of thyroid carcinoma vary with the type:

- Papillary carcinoma (85%):
  1. Most frequently occurs in women during second or third decades
  2. Histologically, psammoma bodies (calcific bodies present in papillary projections) are pathognomonic; found in 35% to 45% of papillary thyroid carcinomas
  3. Majority are not papillary lesions but mixed papillary follicular carcinomas
  4. Spread is by lymphatics and by local invasion
- Follicular carcinoma (10%):
  1. More aggressive than papillary carcinoma
  2. Incidence increases with age
  3. Tends to metastasize hematogenously to bone, producing pathologic fractures
  4. Tends to concentrate iodine (useful for radiation therapy)
- Anaplastic carcinoma (1%):
  1. Very aggressive neoplasm
  2. Two major histologic types: Small cell (less aggressive, 5-yr survival approximately 20%) and giant cell (death usually within 6 mo of diagnosis)
- MTC (4%):
  1. Unifocal lesion: Found sporadically in elderly patients
  2. Bilateral lesions: Associated with pheochromocytoma and hyperparathyroidism; this combination is known as MEN-II and is inherited as an autosomal-dominant disorder

LABORATORY TESTS

- Thyroid function studies are generally normal. Thyroid-stimulating hormone (TSH), T4, and serum thyroglobulin levels should be obtained before thyroidectomy in patients with confirmed thyroid carcinoma. Serum thyroglobulin levels can be useful postoperatively to monitor recurrence of thyroid carcinoma (Fig. E2).
- Increased plasma calcitonin assay in patients with medullary carcinoma (tumors produce thyrocalcitonin). RET proto-oncogene sequencing and measurement of plasma free metanephrine and normetanephrine levels to rule out coexistent pheochromocytoma are recommended in all patients with medullary thyroid cancer.
- Fine-needle aspiration biopsy is the best method to assess a thyroid nodule (see "Thyroid Nodule" in Section I). Table 3 describes the Bethesda system for thyroid cytopathology.

IMAGING STUDIES (FIG. E3)

- Thyroid ultrasound can detect solitary solid nodules that have a high risk of malignancy. However, a negative ultrasound does not exclude diagnosis of thyroid carcinoma.
- Thyroid scanning with iodine-123 or technetium-99m can identify hypofunctioning (cold) nodules, which are more likely to be malignant. However, warm nodules can also be malignant.

STAGING

- Stage I: Thyroid cancer of any size without distal spread in patient <45 yr. In patients >45 yr, tumor size ≤2 cm without local invasion or positive cervical lymph nodes
- Stage II: Distal spread in patient <45 yr. In patients >45 yr, tumors >2 cm but <4 cm without local invasion or positive cervical lymph nodes
- Stage III: Tumors >4 cm in patient >45 yr of age
- Stage IV: Distal spread in patient >45 yr of age

TREATMENT

ACUTE GENERAL Rx

- Papillary carcinoma:
  1. Total thyroidectomy is indicated if the patient has:
     a. Extrapyramidal extension of carcinoma.
     b. Papillary carcinoma limited to thyroid but a positive history of irradiation to the neck.
     c. Lesion >2 cm.
  2. Lobectomy with isthmectomy may be considered in patients with intra-thyroid papillary carcinoma <2 cm and no history of neck or head irradiation; surgery should be followed with suppressive therapy with thyroid hormone because these tumors are TSH responsive. The accepted practice is to suppress serum TSH concentrations to <0.1 microunit/ml in patients with persistent disease, suppression to 0.1 to 0.5 microunit/ml in patients who are disease free but are at high risk of recurrence, and a goal TSH level of 0.3 to 2.0 microunits/ml in patients who are disease free and have a low risk of recurrence.

3. Radioiodine ablation reduces rates of death and recurrence (Table 4). Radioiodine is administered for stages III and IV disease.
4. In cases that have progressed after radioiodine therapy, oral targeted inhibitors (lenvatinib, sorafenib) have significant survival benefit.

- Follicular carcinoma:
  1. Total thyroidectomy followed by TSH suppression, as previously noted.
  2. Radiotherapy with iodine-131 followed by thyroid suppression therapy with triiodothyronine is useful in patients with metastasis (Table 4).
  3. In cases that have progressed after radioiodine therapy, oral targeted inhibitors (lenvatinib, sorafenib) have significant survival benefit.
- Anaplastic carcinoma:
  1. At diagnosis, this neoplasm is rarely operable; palliative surgery is indicated for extremely large tumor compressing the trachea.
  2. Management is usually restricted to radiation therapy or chemotherapy (combination of doxorubicin, cisplatin, and other antineoplastic agents) (Table 4); these measures rarely provide significant palliation.
- Medullary carcinoma:
  1. Thyroidectomy should be performed, followed by TSH suppression.
  2. Vandetanib and cabozantinib are oral tyrosine kinase inhibitors that are FDA-approved for treatment of symptomatic or progressive, unresectable, locally advanced or metastatic medullary thyroid cancer.
  3. Patients and their families should be screened for pheochromocytoma and hyperparathyroidism.

DISPOSITION

Overall 5 yr survival rate is 98.17, but prognosis varies with the type of thyroid carcinoma: 5-yr survival is over 80% for follicular carcinoma and is approximately 5% with anaplastic carcinoma (see Table 5).

PEARLS & CONSIDERATIONS

COMMENTS

- Follow-up surveillance involves neck ultrasound 6-12 mo after initial treatment and periodically and lab evaluation with TSH, serum thyroglobulin (T8), and thyroglobulin antibody (T8 Ab).
- Family members of patients with medullary carcinoma should be screened; DNA analysis for the detection of mutations in the *RET* gene structure permits the identification of *MEN IIA* gene carriers.
- While there is little controversy regarding the benefit of radioactive iodine in iodine-avid advanced-stage well-differentiated thyroid cancer, the indications for radioactive iodine

TABLE 2 Thyroid Malignancies—Key Features

	Description	Pattern of Spread
Papillary carcinoma (70%-80%)	Low-grade tumors with a good prognosis (histologically multicentric) ▸ Tumors concentrate radio-iodine	Early lymph node spread (metastatic lymph nodes may be normal in size, cystic, calcified, hemorrhagic or contain colloid) ▸ Distant metastases are rare (and usually to the lungs)
Follicular carcinoma (10%-20%)	Slow growing ▸ Tumors concentrate radio-iodine	It rarely metastasizes to the regional lymph nodes ▸ The tendency is to spread via the bloodstream and disseminate to the lungs, bones, or liver
Anaplastic carcinoma (1%-2%)	Undifferentiated malignant tumors that do not concentrate radio-iodine ▸ There is a poor prognosis ▸ They tend to occur in older patients ▸ Punctate calcification and necrosis frequently are present	Lymphatic metastases occur in the majority of patients
Medullary carcinoma (5%-10%)	This originates from the parafollicular C cells ▸ It does not concentrate radio-iodine ▸ It may be sporadic or familial (and associated with the MEN type II syndrome or other endocrine neoplasms) ▸ It is usually a unilateral, solitary lesion ▸ Calcification is seen in 10% ▸ ^{123}I-MIBG and somatostatin analogs (e.g. octreotide) can be used for evaluation ▸ Circulating calcitonin levels are usually elevated	It may invade locally, spread to the regional nodes, or demonstrate hematogenous spread to the lungs, bones, or liver
Lymphoma (10%)	It is usually a non-Hodgkin lymphoma ▸ It occurs in one third of patients with Hashimoto thyroiditis (a MALT-type lymphoma) ▸ It presents as a rapidly enlarging, solitary nodule (80%) or as multiple nodules (imaging cannot distinguish between a lymphoma and thyroiditis) ▸ Necrosis and calcification are uncommon	It can involve the nodes with spread to the GI tract
Metastases (<1%)	The most common primary is renal cell carcinoma	

From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.

TABLE 3 The Bethesda System for Thyroid Cytopathology

Category	Risk of Malignancy (%)	Recommended Management
Nondiagnostic or unsatisfactory	1-4	Repeat FNA with ultrasound guidance
Benign	0-3	Clinical follow-up
Atypia of undetermined significance (AUS) or follicular lesion of undetermined significance (FLUS)	5-15	Repeat FNA*
Follicular neoplasm or suspicious for follicular neoplasm	15-30	Lobectomy
Suspicious for malignancy	60-75	Lobectomy with or without frozen section or total thyroidectomy
Malignant	97-99	Total thyroidectomy

*Lobectomy also can be considered depending on clinical or sonographic characteristics.
FNA, Fine-needle aspiration.
From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE 4 Indications for Iodine-131 Treatment in Patients with Papillary, Follicular, or Hürthle Cell Thyroid Carcinoma after Initial Definitive Near-Total Thyroidectomy

No Indication
Adult patients at very low risk for cause-specific mortality or relapse: Complete surgical resection, favorable histology, and limited extent of disease (e.g., PTC patients with MACIS scores <6; patients with tumor size <1 cm, N0, and M0).
Definite Indications
Distant metastasis at diagnosis
Incomplete tumor resection
Complete tumor resection but high risk for mortality or recurrence (e.g., PTC patients with MACIS scores ≥6 and pTNM stage II/III FTC or HCC)
Probable Indications
Incomplete surgery (less than near-total thyroidectomy, no lymph node dissection)
PTC or FTC in a child younger than 16 yr
If PTC, tall cell or columnar cell variant and diffuse sclerosing variant
If FTC, widely invasive or poorly differentiated tumor
Bulky nodal metastases

FTC, Follicular thyroid carcinoma; *HCC,* Hürthle cell carcinoma; *MACIS,* scoring system based on metastasis, age, completeness of resection, invasion, and size; *PTC,* papillary thyroid carcinoma; *pTNM,* pathologic tumor-node-metastasis classification.
From Melmed S et al (eds): *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.

TABLE 5 Characteristics of Thyroid Cancers

Type of Cancer	Percentage of Thyroid Cancers	Age of Onset (yr)	Treatment	Prognosis
Papillary	88	40-80	Thyroidectomy, followed by radioactive iodine ablation and TSH suppression	Good
Follicular	10	45-80	Thyroidectomy, followed by radioactive iodine ablation and TSH suppression	Fair to good
Medullary	3-4	20-50	Thyroidectomy and central compartment lymph node dissection and TSH suppression	Fair
Anaplastic	1	50-80	Isthmusectomy followed by palliative x-ray treatment	Poor
Lymphoma	<1	25-70	X-ray therapy and/or chemotherapy	Fair

From Andreoli TE et al: *Andreoli and Carpenter's Cecil essentials of medicine,* ed 8, Philadelphia, 2010, Saunders.

following total thyroidectomy in patients with very low risk disease is controversial. Proponents argue that its use may destroy microscopic metastases, while opponents counter that the risk of secondary cancer due to radioactive iodine is not warranted in patients whose prognosis is typically excellent.

- Metastatic thyroid cancers that are refractory to radioiodine (iodine-131) are associated with a poor prognosis.
- Small-molecule tyrosine kinase inhibitors, including vandetanib, cabozantinib, sorafenib, and lenvatinib, are now FDA-approved and have shown clinical benefit with improved survival in advanced differentiated and medullary thyroid cancer.
- Targeted therapy with a combined regimen of BRAF inhibitors and MEK inhibitors (dabrafenib plus trametinib) is efficacious and approved in patients with metastatic BRAFV600E-mutated anaplastic thyroid cancer.
- In a subset of patients with anaplastic thyroid cancer, the immune checkpoint inhibitor pembrolizumab may be an effective salvage therapy when added to kinase inhibitors at the time of progression on these drugs. In patients with advanced, differentiated thyroid cancer, pembrolizumab has a manageable safety profile and demonstrates evidence of antitumor activity in a minority of treated patients.

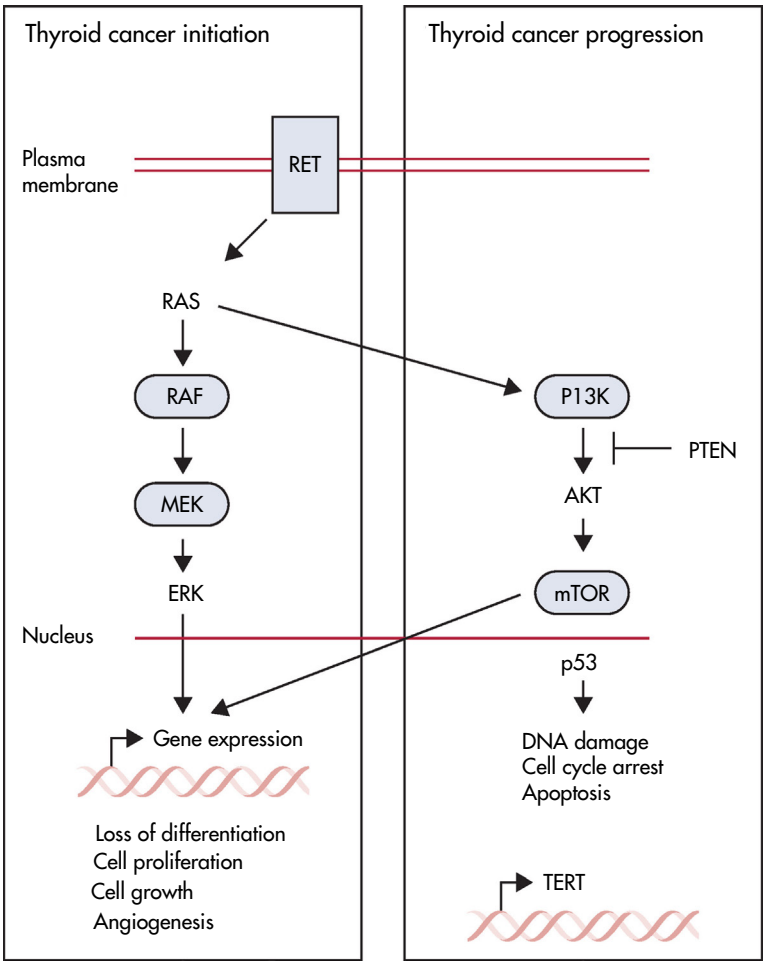

FIG. E1 Thyroid cancer pathways. Diagram shows the key molecular signaling pathways involved in thyroid cancer. The box on the left shows the mitogen-activated protein kinase pathway, which is activated by mutation in most thyroid cancers. These events are believed to initiate thyroid cancer development and lead to altered gene expression, which promotes cell proliferation, cell growth, angiogenesis, and loss of differentiation. The box on the right shows pathways altered in advanced thyroid cancers, which are believed to promote tumor progression. This includes the PI3K–mTOR pathway, the p53 tumor suppressor, and alterations in the promoter for TERT. Blue boxes represent factors for which targeted treatments are available that have been approved by the U.S. Food and Drug Administration. *mTOR,* Mammalian target of rapamycin; *PI3K,* phosphatidylinositol-3-kinase; *TERT,* telomerase reverse transcriptase. (From Cabanillas ME et al: Thyroid cancer, *Lancet* 388[10061]:2783-2795, 2016.)

FIG. E2 This patient was being monitored for a papillary thyroid carcinoma treated by total thyroidectomy and postoperative radioiodine. The serum thyroglobulin level was 45 ng/ml during levothyroxine suppressive treatment. **A,** A total-body scan was performed 3 days after administration of 100 mCi (3.7 GBq). There is no visible uptake in the neck or thorax. Notice the accumulation of radioiodine in the stomach, colon, and bladder. **B,** Positron emission tomography scan using [18F]-fluorodeoxyglucose (18FDG) with maximal intensity projection demonstrates significant uptake in the upper mediastinum. **C,** In fusion images of 18FDG-PET and CT scans, axial and coronal slices localized the FDG uptake in the right paratracheal mediastinum, corresponding to a lymph node metastasis that subsequently was excised. Serum thyroglobulin became undetectable during thyroid hormone treatment. (From Melmed S et al [eds]: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.)

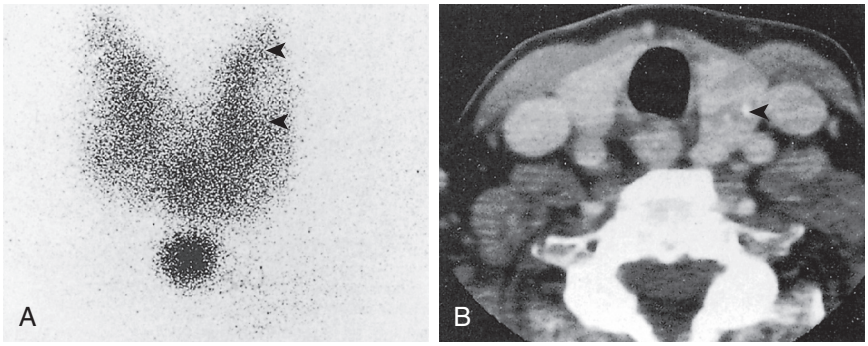

FIG. E3 Papillary adenocarcinoma. A 74-year-old woman presented with a thyroid nodule. **A,** An ^{123}I thyroid scan (anterior view) demonstrates a "cold" nodule *(arrows)* in the upper portion of the left thyroid lobe. The "hot" spot below the thyroid is a suprasternal marker. **B,** An axial computed tomography scan demonstrates an irregular density in the left thyroid lobe at the level of the lesion seen on the radionuclide scan. The lesion contains a single area of calcification *(arrow)* and is not demarcated sharply from normal thyroid tissue. At operation, there proved to be extracapsular extension. (From Skarin AT: *Atlas of diagnostic oncology,* ed 3, St Louis 2003, Mosby.)

Thyroid Nodule PTG ALG

BASIC INFORMATION

DEFINITION

A thyroid nodule is an abnormality found on physical examination of the thyroid gland; nodules can be benign (70%) or malignant.

ICD-10CM CODES

E04.1	Nontoxic single thyroid nodule.
E05.2	Thyrotoxicosis with toxic single thyroid nodule.
E05.11	Thyrotoxicosis with toxic single thyroid nodule with thyrotoxic crisis or storm

EPIDEMIOLOGY & DEMOGRAPHICS

- Thyroid nodules are detected in 40% of the U.S. population.
- Thyroid nodules can be found in 50% of autopsies; however, only one in 10 is palpable.
- Malignancy is present in 5% to 15% of all thyroid nodules and in 7% to 9% of palpable nodules.
- Incidence of thyroid nodules increases after 45 yr. They are found more frequently in women (5% of women; 1% of men).
- History of prior head and neck irradiation increases the risk of thyroid cancer.
- Increased likelihood that nodule is malignant: Nodule increasing in size or >3 cm, regional lymphadenopathy, fixation to adjacent tissues, age <40 yr, symptoms of local invasion (dysphagia, hoarseness, neck pain, male sex, family history of thyroid cancer or polyposis [Gardner syndrome]), rapid growth during levothyroxine therapy, microcalcification within the nodule, and high intranodular vascular flow.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Palpable, firm, and nontender nodule in the thyroid area should prompt suspicion of carcinoma. Signs of metastasis are regional lymphadenopathy and inspiratory stridor.
- Signs and symptoms of thyrotoxicosis can be found in functioning nodules.

ETIOLOGY

- History of prior head and neck irradiation
- Family history of pheochromocytoma, carcinoma of the thyroid, and hyperparathyroidism (medullary carcinoma of the thyroid is a component of MEN-II)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Thyroid carcinoma
- Multinodular goiter
- Thyroglossal duct cyst
- Epidermoid cyst
- Laryngocele
- Nonthyroid neck neoplasm
- Branchial cleft cyst

WORKUP

- Ultrasonography is an inexpensive and effective modality to stratify malignancy risk.
- Fine-needle aspiration (FNA) biopsy is the best diagnostic study; the accuracy can be >90%, but it is directly related to the level of experience of the physician and the cytopathologist interpreting the aspirate. FNA is not routinely recommended for thyroid nodules <1 cm in diameter unless there are significant risk factors (see earlier).
- FNA biopsy is less reliable with thyroid cystic lesions; surgical excision should be considered for most thyroid cysts not abolished by aspiration.
- A diagnostic approach to thyroid nodule is described in Fig. 1. Preoperative, ultrasonically guided FNA accurately classifies 62% to 85% of thyroid nodules as benign; however, 15% to 30% of aspirations yield indeterminate cytologic findings. Table 1 describes the probability of malignancy at histology based on FNA biopsy cytology.

LABORATORY TESTS

- Serum TSH should be obtained in all patients with thyroid nodules. If suppressed, obtain free T4 and free T3 and thyroid scan to rule out "hot nodule," indicative of hyperthyroid adenoma. Less than 1% of hyperfunctioning nodules are malignant. Typically FNA biopsy is not necessary in hot nodules.
- Thyroid-stimulating hormone (TSH), T4, and serum thyroglobulin levels should be obtained before thyroidectomy in patients with confirmed thyroid carcinoma on FNA biopsy.
- Serum calcitonin at random or after pentagastrin stimulation is useful when suspecting medullary carcinoma of the thyroid and in anyone with a family history of medullary thyroid carcinoma.
- Serum thyroid autoantibodies (see "Thyroiditis" in Section I) are useful in patients with multinodular goiter and when suspecting thyroiditis.
- Molecular analysis of thyroid tissue for the presence of *BRAF* and *RAS* mutations and for *RET/PTC* and *PAX8-PPAR* gamma 1 gene rearrangements can be used as a diagnostic tool, since 60% to 70% of thyroid cancers harbor at least one genetic mutation. The gene expression classifier profile can be used to identify a subpopulation of patients with a low likelihood of cancer, thereby avoiding unnecessary surgery in patients with indeterminate FNA. The gene expression classifier test has a high negative predictive value for cytologically indeterminate nodules (95% for an atypical or follicular lesion of undetermined significance, 94% for a follicular neoplasm, and 85% for a lesion suggestive of cancer).

IMAGING STUDIES

- Thyroid ultrasound (Fig. E2) is useful to evaluate the size of the thyroid and the number, composition (solid versus cystic), and dimensions of the thyroid nodule; solid thyroid nodules have a higher incidence of malignancy, but cystic nodules can also be malignant. Table E2 summarizes ultrasound features of benign and malignant thyroid nodules. The three characteristics on thyroid ultrasound most predictive of cancer are nodules >2 cm, microcalcifications, and entirely solid nodules.
- Thyroid scan can be performed with technetium-99m pertechnetate, iodine-123, or iodine-131. Iodine isotopes are preferred because up to 35% of nodules that appear functioning on pertechnetate scanning may appear nonfunctioning on radioiodine scanning. A thyroid scan:
  1. Classifies nodules as hyperfunctioning (hot), normally functioning (warm), or nonfunctioning (cold); cold nodules have a higher incidence of malignancy.
  2. Scan has difficulty evaluating nodules near the thyroid isthmus or at the periphery of the gland.
  3. Normal tissue over a nonfunctioning nodule might mask the nodule as "warm" or normally functioning.
- Both thyroid scan and ultrasound provide information about the risk of malignant neoplasia based on the characteristics of the thyroid nodule, but their value in the initial evaluation of a thyroid nodule is limited because neither provides a definite tissue diagnosis.

TREATMENT

GENERAL Rx

- Evaluation of results of FNA:
  1. Normal cells: May repeat biopsy during present evaluation or reevaluate patient after 3 to 6 mo of suppressive therapy (L-thyroxine, prescribed in doses to suppress the TSH level to 0.1 to 0.5).
     a. Failure to regress indicates increased likelihood of malignancy.
     b. Reliance on repeat FNA biopsy is preferable to routine surgery for nodules not responding to thyroxine.
- Indeterminate: Use of gene expression classifier profile. If suspicious, perform surgery; if benign, monitor with subsequent repeat FNA and gene expression classifier profile.
- Malignant cells: Surgery.

DISPOSITION

Variable with results of FNA biopsy

REFERRAL

Surgical referral for FNA biopsy

PEARLS & CONSIDERATIONS

COMMENTS

- Most solid, benign nodules grow; therefore, an increase in nodule volume alone is not a reliable predictor of malignancy.
- Thyroid nodules incidentally identified on fluorodeoxyglucose-PET (FDG-PET) scan done for other disorders has a much higher malignancy rate (30% to 50%).

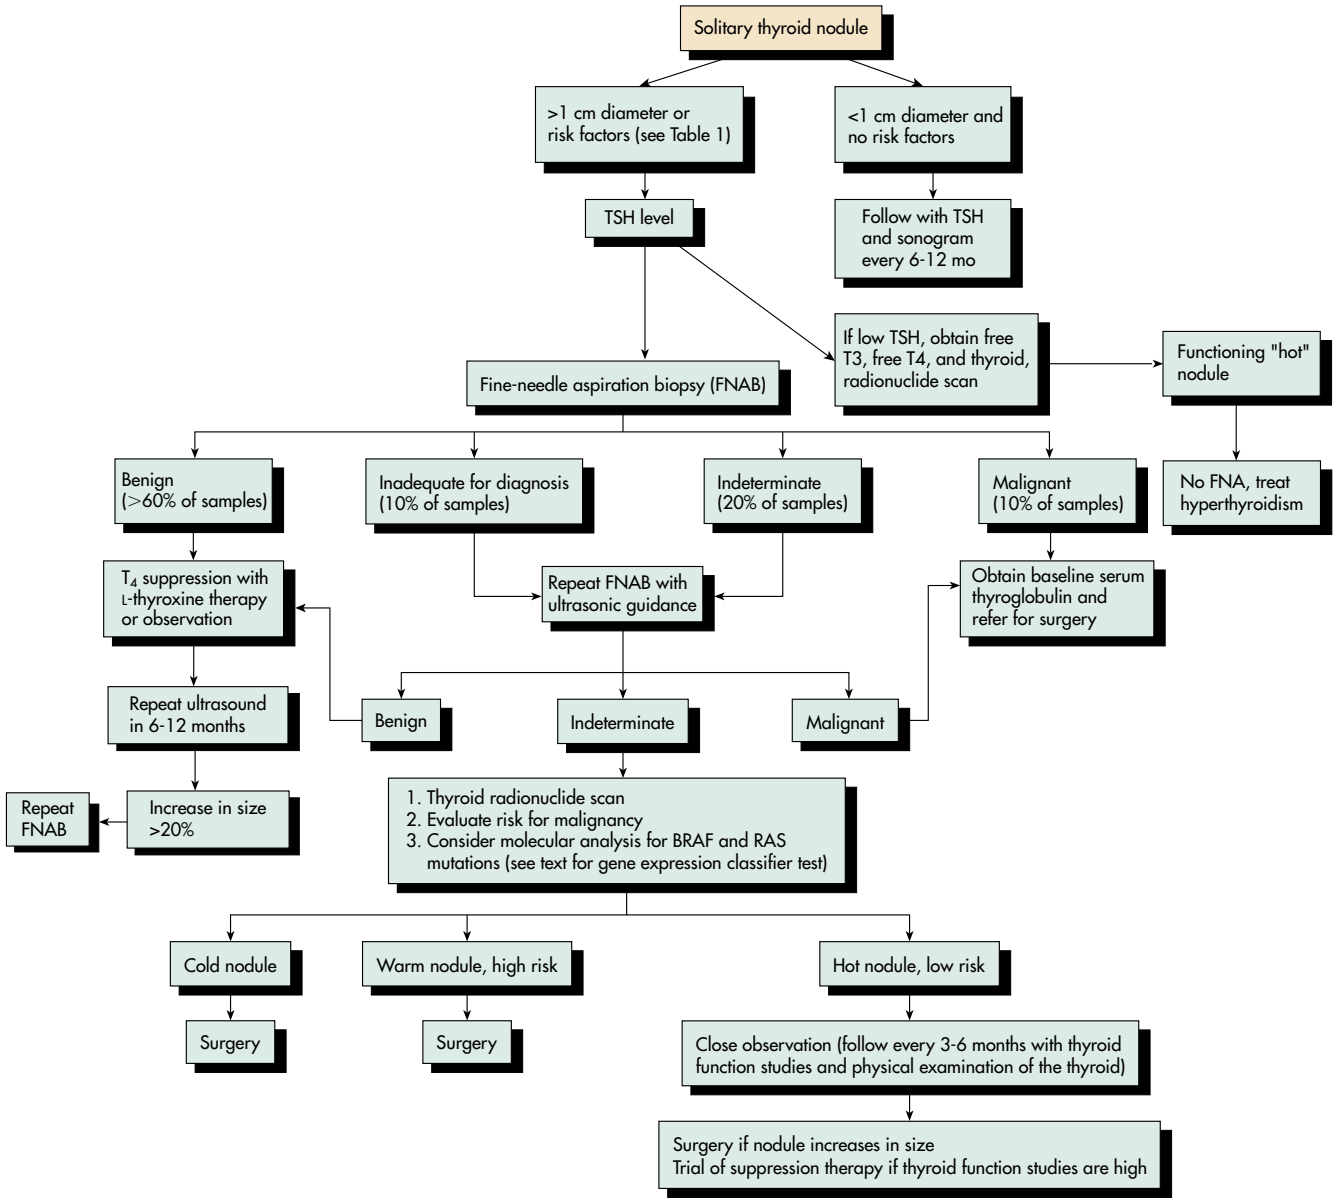

FIG. 1 Diagnostic algorithm for thyroid nodule. *FNA,* Fine needle aspiration; *T3,* triiodothyronine; *T4,* thyroxine; *TSH,* thyroid-stimulating hormone. (From Ferri F: *Ferri's best test,* ed 4, Philadelphia, Elsevier, 2017.)

TABLE 1 Clinical and Ultrasound Findings in Favor of Malignant Thyroid Nodules

Clinical Features	Ultrasound Findings
History	Higher suspicion
Young age (<20 yr) or older age (>60 yr)	Hypoechoic lesions
Male gender	Irregular margins
Neck irradiation during childhood or adolescence	Presence of microcalcifications
Rapid growth	Absence of halo
Recent changes in speaking, breathing, or swallowing	Internal or central blood flow
Family history of thyroid malignancy or MEN2	
Physical examination	Low suspicion
Firm and irregular consistency of nodule	Echo-free (cystic) lesion
Fixation to underlying or overlying tissues	Spongiform lesion
Vocal cord paralysis	
Regional lymphadenopathy	

MEN2, Multiple endocrine neoplasia II.
From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Elsevier.

- Surgery is indicated in hard or fixed nodule, presence of dysphagia or hoarseness, and rapidly growing solid masses regardless of "benign" results on FNA.
- Suppressive therapy of malignant thyroid nodules postoperatively with thyroxine is indicated. The use of suppressive therapy for benign solitary nodules is controversial.

TABLE E2 US Features of Benign and Malignant Thyroid Nodules (FNAC is still required for suspicious lesions)

	Benign	Malignant
Nodule characteristics	• A cystic nodule ± debris ± septations ▸ A sponge-like nodule • Posterior acoustic shadowing • A hyperechoic nodule • 'Comet tail' artefact (colloid nodule) • Multiple isoechoic nodules (multinodular goiter) • Multiple hypoechoic nodules (Hashimoto thyroiditis) • Indeterminate: A solid, well-defined nodule ± cystic components	• Solid nodules protruding into the cystic space • No posterior acoustic shadowing
Peripheral halo	• A thin, uniform halo	• An incomplete, irregular, or thickened halo
Nodule margin	• Smooth, regular margins	• An irregular, lobulated, or poorly defined margin
Calcification	• This is generally absent (eggshell calcification may be present)	• Microcalcification ▸ Fine or coarse calcification (commonly papillary or medullary carcinomas)
Metastatic spread		• Invasion of the adjacent tissues ± enlarged ipsilateral or bilateral cervical lymph nodes

From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.

BASIC INFORMATION

DEFINITION

Thyroiditis is an inflammatory disease of the thyroid. It is a multifaceted disease with various etiologies, different clinical characteristics (depending on the stage), and distinct histopathology. Thyroiditis can be subdivided into three common types (Hashimoto, painful, and painless) and two rare forms (suppurative and Riedel). To add to the confusion, there are various synonyms for each form, and there is no internationally accepted classification of autoimmune thyroid disease.

SYNONYMS

Hashimoto thyroiditis: Chronic lymphocytic thyroiditis, chronic autoimmune thyroiditis, lymphadenoid goiter

Painful subacute thyroiditis: Subacute thyroiditis, giant cell thyroiditis, de Quervain thyroiditis, subacute granulomatous thyroiditis, pseudogranulomatous thyroiditis

Painless postpartum thyroiditis: Subacute lymphocytic thyroiditis, postpartum thyroiditis

Painless sporadic thyroiditis: Silent sporadic thyroiditis, subacute lymphocytic thyroiditis

Infectious thyroiditis: Acute suppurative thyroiditis, bacterial thyroiditis, microbial inflammatory thyroiditis, pyogenic thyroiditis

Riedel thyroiditis: Fibrous thyroiditis

ICD-10CM CODES

E06.3 Autoimmune thyroiditis
E06.1 Subacute thyroiditis
E06.9 Thyroiditis, unspecified
E06.0 Acute thyroiditis
E06.5 Other chronic thyroiditis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Thyroiditis typically has three phases: thyrotoxic and hypothyroid (each lasting approximately 3 mo) and return to euthyroidism.
- Hashimoto: Patients may have signs of hyperthyroidism (tachycardia, diaphoresis, palpitations, weight loss) or hypothyroidism (fatigue, weight gain, delayed reflexes) depending on the stage of the disease. Usually there is diffuse, firm enlargement of the thyroid gland; the gland may also be of normal size (atrophic form with clinically manifested hypothyroidism).
- Painful subacute: Exquisitely tender, enlarged thyroid, fever; signs of hyperthyroidism are initially present; signs of hypothyroidism can subsequently develop.
- Painless thyroiditis: Clinical features are similar to subacute thyroiditis except for the absence of tenderness of the thyroid gland.
- Suppurative: Patient is febrile with severe neck pain, focal tenderness of the involved portion of the thyroid, erythema of the overlying skin.
- Riedel: Slowly enlarging hard mass in the anterior neck; often mistaken for thyroid cancer; signs of hypothyroidism occur in advanced stages.

ETIOLOGY

- Hashimoto: Autoimmune disorder that begins with the activation of CD4 T-helper lymphocytes specific for thyroid antigens. The etiologic factor for the activation of these cells is unknown
- Painful subacute: Possibly postviral; usually follows a respiratory illness not considered to be a form of autoimmune thyroiditis
- Painless thyroiditis: Frequently occurs postpartum
- Infectious (suppurative): Infectious etiology, generally bacterial, although fungi and parasites have also been implicated; often occurs in immunocompromised hosts or after a penetrating neck injury
- Riedel: Fibrous infiltration of the thyroid; etiology unknown
- Drug induced: Typically painless due to lithium, interferon-alfa, amiodarone, interleukin-2
- Radiation thyroiditis: Occurs 5 to 10 days after treatment with radioactive iodine; it is painful and may result in transient exacerbation of hyperthyroidism

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The hyperthyroid phase of Hashimoto, subacute, and silent thyroiditis can be mistaken for Graves disease.
- Riedel thyroiditis can be mistaken for carcinoma of the thyroid.
- Painful subacute thyroiditis can be mistaken for infections of the oropharynx and trachea or for suppurative thyroiditis.
- Factitious hyperthyroidism can mimic silent thyroiditis.

WORKUP

- The diagnostic workup includes laboratory and radiologic evaluation to rule out other conditions that may mimic thyroiditis (see previously) and differentiate the various forms of thyroiditis.
- The patient's medical history may be helpful in differentiating the various types of thyroiditis (e.g., presentation after childbirth is suggestive of silent [postpartum, painless] thyroiditis; occurrence after a viral respiratory infection suggests subacute thyroiditis; history of penetrating injury to the neck indicates suppurative thyroiditis).

LABORATORY TESTS

- Thyroid-stimulating hormone, free T4: May be normal or indicative of hypothyroidism or hyperthyroidism depending on the stage of the thyroiditis.
- White blood cell (WBC) with differential: Increased WBC with left shift occurs with subacute and suppurative thyroiditis.
- Antimicrosomal antibodies: Detected in >90% of patients with Hashimoto thyroiditis and 50% to 80% of patients with silent thyroiditis.
- Serum thyroglobulin levels are elevated in patients with subacute and silent thyroiditis; this test is nonspecific but may be useful in monitoring the course of subacute thyroiditis and distinguishing silent thyroiditis from factitious hyperthyroidism (low or absent serum thyroglobulin level).

IMAGING STUDIES (FIGS. E1 and E2)

24-hr radioactive iodine uptake (RAIU) is useful to distinguish Graves disease (increased RAIU) from thyroiditis (normal or low RAIU). Table E1 summarizes factors that influence 24-hr thyroid iodide uptake.

TREATMENT

ACUTE GENERAL Rx

- The duration of the thyrotoxic phase of thyroiditis is usually 10 to 12 wk. This phase is followed by a hypothyroid phase typically lasting up to 12 wk.
- Treat hypothyroid phase in symptomatic patients somatic with levothyroxine 25 to 50 mcg/day initially and monitor serum thyroid-stimulating hormone initially every 6 to 8 wk.
- Control symptoms of hyperthyroidism with beta-blockers (e.g., propranolol 20 to 40 mg PO q6h or atenolol).
- Control pain in patients with subacute thyroiditis with nonsteroidal antiinflammatory drugs. Prednisone 20 to 40 mg qd may be used if nonsteroidals are insufficient, but it should be gradually tapered off over several wk.
- Use IV antibiotics and drain abscess (if present) in patients with suppurative thyroiditis.

DISPOSITION

- Hashimoto thyroiditis: Long-term prognosis is favorable; most patients recover their thyroid function.
- Painful subacute thyroiditis: Permanent hypothyroidism occurs in 10% of patients.
- Painless thyroiditis: 6% of patients have permanent hypothyroidism.
- Infectious thyroiditis: There is usually full recovery after treatment.
- Riedel thyroiditis: Hypothyroidism occurs when fibrous infiltration involves the entire thyroid.

REFERRAL

- Surgical referral in patients with compression of adjacent neck structures and in some patients with infectious (suppurative) thyroiditis
- Total thyroidectomy has been shown to improve symptoms in patients with Hashimoto thyroiditis who still have symptoms despite having normal thyroid gland function while receiving medical therapy.[1]

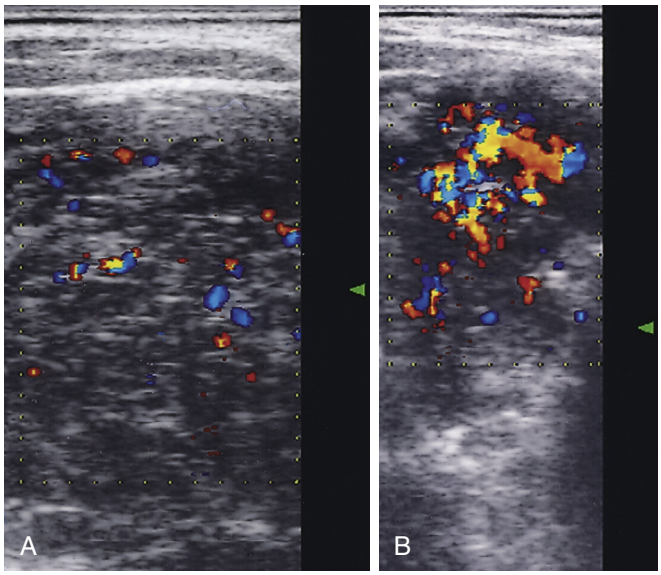

FIG. E1 A, Longitudinal ultrasound through the left lobe of the thyroid in a patient known to have Hashimoto thyroiditis reveals a loose, heterogeneous echotexture with abnormal color flow. There are enlarged neck nodes **(B),** again with abnormal color flow in this patient, who has developed lymphoma. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

FIG. E2 Thyroid scintigraphy demonstrating chronic thyroiditis affecting only the right lobe. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia, 2019, Elsevier.)

TABLE E1 Factors That Influence 24-Hour Thyroid Iodide Uptake

Factors that Increase Uptake

Increased Hormone Synthesis

Hyperthyroidism

Response to glandular hormone depletion:
- Recovery from thyroid suppression
- Recovery from subacute thyroiditis
- Antithyroid agents

Excessive Hormone Losses
- Nephrotic syndrome
- Chronic diarrheal states
- Soybean ingestion

Normal Hormone Synthesis

Iodine deficiency:
- Dietary insufficiency
- Excessive loss (dehalogenase defect, pregnancy)

Hormone biosynthetic defects

Factors that Decrease Uptake

Decreased Hormone Synthesis

Primary hypofunction:
- Primary hypothyroidism
- Antithyroid agents
- Hormone biosynthetic defects
- Hashimoto disease
- Subacute thyroiditis

Secondary hypofunction

Exogenous thyroid hormones

Not Reflecting Decreased Hormone Synthesis

Increased availability of iodine:
- Diet or drugs
- Cardiac or renal insufficiency

Increased hormone release

Very severe hyperthyroidism (rare)

From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Elsevier.

Thyrotoxic Storm

BASIC INFORMATION

DEFINITION

Thyrotoxic storm is the abrupt and severe exacerbation of thyrotoxicosis. It is an acute, life-threatening complication of hyperthyroidism.

SYNONYM

Thyroid storm

ICD-10CM CODE
E05.5 Thyroid crisis or storm

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Tremor, tachycardia/tachyarrhythmias, fever (as high as 105.8 °F [41 °C])
- Sweating, diarrhea, vasodilation
- Lid lag, lid retraction, proptosis
- Altered mental status (psychosis, coma, seizures)
- Goiter
- Other: Evidence of precipitating factors (infection, trauma), congestive heart failure [CHF], hepatosplenomegaly, jaundice

ETIOLOGY

- Precipitating factors: Surgery, infection, myocardial infarction or cardiac disease, diabetic ketoacidosis, labor, iodinated IV contrast agents, radioactive iodine therapy
- Inadequate therapy in a hyperthyroid patient

DIAGNOSIS

The clinical presentation is variable. The patient may present with the following signs and symptoms:

- Fever
- Marked anxiety and agitation, psychosis
- Hyperhidrosis, heat intolerance
- Marked weakness and muscle wasting
- Tachyarrhythmias, palpitations
- Diarrhea, nausea, vomiting
- Elderly patients may have a combination of tachycardia, CHF, and mental status changes Although the diagnosis is based on clinical presentation, it can generally be ruled out if T_4 and T_3 levels are within normal limits

DIFFERENTIAL DIAGNOSIS

- Psychiatric disorders
- Alcohol or other drug withdrawal
- Pheochromocytoma
- Metastatic neoplasm

WORKUP

- Laboratory evaluation to confirm hyperthyroidism (elevated free T4, decreased thyroid-stimulating hormone [TSH])
- Evaluation for precipitating factors (e.g., ECG and cardiac enzymes in suspected MI, blood and urine cultures to rule out sepsis)
- Elimination of disorders noted in the differential diagnosis (e.g., psychiatric history, evidence of drug and alcohol abuse)

LABORATORY TESTS

- Free T_4, TSH
- Complete blood count with differential
- Blood and urine cultures
- Glucose
- Liver enzymes
- Blood urea nitrogen, creatinine
- Serum calcium
- Creatine phosphokinase

IMAGING STUDIES

Chest x-ray to exclude infectious process, neoplasm, CHF in suspected cases

TREATMENT

NONPHARMACOLOGIC THERAPY

- Nutritional care: Replace fluid deficit aggressively (daily fluid requirement may reach 6 L); use solutions containing glucose and add multivitamins to the hydrating solution.
- Monitor for fluid overload and CHF in the elderly and in those with underlying cardiovascular or renal disease.
- Treat significant hyperthermia with cooling blankets.

ACUTE GENERAL Rx

- Inhibition of thyroid hormone synthesis:
  1. Administer propylthiouracil (PTU) 800 mg initially (PO or by nasogastric tube)/PR, then 200 to 300 mg PO/PR q6h. PTU is preferred over methimazole because it has the added benefit of blocking peripheral conversion of T_4 to T_3
  2. If the patient is allergic to PTU, use methimazole 80 to 100 mg (PO or by nasogastric tube)/PR followed by 40 mg PO/PR q8h. Methimazole can also be administered IV 60 to 120 mg daily, divided doses
- Inhibition of stored thyroid hormone release from the gland:
  1. Sodium iodide 1 g IV over 24 hours or potassium iodide (oral) 5 drops 4 times/day (super-saturated potassium iodide). It is important to administer PTU or methimazole 1 hr *before* the iodide to prevent the oxidation of iodide to iodine and its incorporation in the synthesis of additional thyroid hormone
  2. Corticosteroids: Dexamethasone 1 to 2 mg IV q6h or hydrocortisone 100 mg IV q6h for approximately 48 hr is useful to inhibit thyroid hormone release, impair peripheral conversion of T_3 from T_4, and provide additional adrenocortical hormone to correct deficiency (if present)
- Suppression of peripheral effects of thyroid hormone:
  1. Beta-adrenergic blockers: Administer propranolol 60 to 80 mg every 4 hours. Propranolol may also be given IV 1 mg/min for 2 to 10 min under continuous ECG and blood pressure monitoring. Beta-adrenergic blockers must be used with caution in patients with severe CHF or bronchospasm. Cardioselective beta-blockers (e.g., esmolol 500 mg IV over 1 min, then 50 to 100 mg/kg/min or metoprolol 5 to 10 mg IV every 2 to 4 hours) may be more appropriate for patients with bronchospasm, but these patients must be closely monitored for exacerbation of bronchospasm because these agents lose their cardioselectivity at high doses. The calcium channel blocker diltiazem can also be given to reduce the heart rate. Dose is 0.25 mg/kg over 2 min, then infusion of 10 mg/min. Oral dose is 60 to 90 mg every 6 to 8 hours
- Control of fever with acetaminophen 325 to 650 mg q4h; avoidance of aspirin because it displaces thyroid hormone from its binding protein
- Treatment of any precipitating factors (e.g., antibiotics if infection is strongly suspected)

DISPOSITION

Patients with thyrotoxic crisis should be treated and appropriately monitored in the ICU.

REFERRAL

Endocrinology referral is appropriate in patients with thyrotoxic crisis.

PEARLS & CONSIDERATIONS

COMMENTS

If the diagnosis is strongly suspected, therapy should be started immediately without waiting for laboratory confirmation.

SUGGESTED READING

McDermott MT: In the clinic: hyperthyroidism, *Ann Intern Med ITC* 3:1-14, 2012.

BASIC INFORMATION

DEFINITION

Tinea capitis is a dermatophyte infection of hair shaft and follicles of the scalp, eyebrows, and eyelashes. It is a form of superficial mycosis. Etiologic agents are fungal species of the genera *Microsporum* and *Trichophyton*.

SYNONYMS

Ringworm of the scalp
Ringworm of the head
Gray patch tinea capitis
Black dot tinea capitis
Tinea tonsurans
Herpes tonsurans
Kerion
Favus

ICD-10CM CODE
B35.0 Tinea barbae and tinea capitis

EPIDEMIOLOGY & DEMOGRAPHICS

Tinea capitis primarily affects prepubertal children with peak age between 3 and 7 yr old. Adult cases are rare, possibly because of the fungistatic effect of the sebum found in older persons. Urban living, large family size, low socioeconomic status, and crowded living conditions may contribute to an increased incidence of tinea capitis. The elderly and immunocompromised individuals have an increased risk of infection. The incidence of the disease varies worldwide; however, it is relatively low in the U.S. It is reportedly widespread in parts of Central and South America, India, and Africa.

In the U.S., peak incidence occurs in school-aged children of low socioeconomic status, with African American male children accounting for the greatest proportion of cases. About 3% to 8% of American children are affected, and 34% of household contacts are asymptomatic carriers.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Classic triad of scalp scaling, alopecia, and cervical adenopathy. Table 1 summarizes clinical manifestations of tinea capitis in children.
- Most forms of tinea capitis begin with one or few round patches of scale (Fig. E1) or alopecia (Fig. E2).
- Primary lesions include plaques, papules, pustules, or nodules on the scalp (usually occipital region).
- Secondary lesions include scales, alopecia (usually reversible), erythema, exudates, and edema.
- Scalp pruritus may be present.
- Fever, pain, and lymphadenopathy (commonly postcervical) may occur with inflammatory lesions.
- Different clinical patterns of tinea capitis have been described:
  1. Gray patch: Lesions are scaly and well demarcated. The hairs within the patch break off a few millimeters above the scalp. One or several lesions may be present; sometimes the lesions join to form larger ones.
  2. Black dot: Early lesions with erythema and scaling patch are easily overlooked until areas of alopecia develop. Hairs within the patches break at the surface of the scalp, leaving behind a pattern of swollen black dots.
  3. Kerion (Fig. E3): Inflamed, exudative, pustular, boggy, tender nodules exhibiting marked edema, and hair loss seen in severe tinea capitis. Caused by immune response to the fungus. May lead to some scarring.
  4. Favus: Production of scutula (hair matted together with dermatophyte hyphae and keratin debris), characterized by yellow cup-shaped crusts around hair shafts. A fetid odor may be present.

TABLE 1 Clinical Manifestations of Tinea Capitis in Children

Clinical Feature	Comment
Scalp	
Alopecia	One or multiple patches; may simulate alopecia areata
Scaling	May be minimally inflammatory; may mimic seborrheic dermatitis
Erythema	Localized or widespread
Pustules	Differential diagnosis includes sterile folliculitis or bacterial folliculitis
"Black dots"	Alopecia with hair shafts broken off at surface of skin; may simulate trichotillomania
Kerion	Boggy, tender plaque with pustules and purulent discharge; represents a vigorous host immune response
Scarring	Rarely seen when untreated; usually follows kerion
Favus	Yellow, cup-shaped crusts around the hair
Other	
Lymphadenopathy	Common; cervical or occipital
Id reaction	Widespread, papular or papulovesicular eruption; extremity-predominant; usually seen after initiation of therapy; must be recognized as distinct from true drug reaction

From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.

ETIOLOGY

Although fungi of the *Microsporum* or *Trichophyton* genera cause most cases of tinea capitis, causative species vary between geographical areas and across time. *T. tonsurans* is the predominant cause of tinea capitis, present in more than 90% of cases in North and Central America. *Microsporum canis, M. audouinii,* and *Trichophyton mentagrophytes* are less common. The most common causative species for black dot tinea capitis is *T. tonsurans*, while gray patch tinea capitis tends to be caused by *M. audouinii* and *M. canis.* Infection of the hair shaft is preceded by invasion of the stratum corneum of the scalp. Transmission of *T. tonsurans* occurs from person-to-person via infected persons or asymptomatic carriers, fallen infected hairs, animal vectors, and fomites. *M. audouinii* is commonly spread by dogs and cats. Infectious fungal particles may remain viable for many mo. Even though the organism remains viable on combs, hairbrushes, and other fomites for long periods of time, the role of fomites in spreading the infection may vary in different geographic areas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Seborrheic dermatitis and psoriasis may be confused with tinea capitis. Other conditions that resemble tinea capitis include alopecia areata, impetigo, pediculosis, trichotillomania, traction alopecia, folliculitis, pseudopelade, seborrhea/atopic dermatitis, psoriasis, carbuncles, pyoderma, lichen ruber planus, and lupus erythematosus; these should also be considered in the differential. Table 2 highlights distinctive features of conditions that may be confused for tinea capitis.

WORKUP

- KOH testing of hair shaft extracted from the lesion, not the scale, because the *T. tonsurans* spores attach to or reside inside hair shafts and will rarely be found in the scales.
- Wood's ultraviolet light fluoresces blue-green on hair shafts for *Microsporum* infections but will fail to identify *T. tonsurans.*
- Fungal culture of hairs and scales on fungal medium such as Sabouraud agar may be used to confirm the diagnosis, especially if uncertain.
- Histology of biopsies with fungal staining in cases where mycology tests are negative because of treatment initiation.

TREATMENT

- Griseofulvin is the gold standard FDA-approved treatment. Published studies show mean efficacy for griseofulvin treatment of about 68% for *Trichophyton* species and 88% for *Microsporum.* It is less costly than other drug options and has an excellent long-term safety profile. Micronized and ultramicronized preparations are absorbed better, and side effects are infrequent, especially when administered with fatty meals. Periodic monitoring of hematologic, liver, and renal function may be indicated, especially in prolonged treatment over 8 wk.
  1. **Children:** Griseofulvin is approved for children older than 2 yr of age: microsize griseofulvin 10 to 25 mg/kg PO per day in one single dose or two divided doses (maximum, 1 g/day; for tinea capitis, higher doses [20 to 25 mg/kg/day] have been recommended) or ultramicrosize

TABLE 2 Differential Diagnosis of Tinea Capitis

Disorder	Differentiating Features
Psoriasis	Red skin with thick, uniform, silvery scale, sharply demarcated; often psoriasis at other body sites also.
Dermatitis	Main possibility is seborrheic dermatitis: Usually more diffuse and has uniform fine scaling, rather than localized areas; doesn't typically cause alopecia or significant inflammation. May also be present on the face, especially the nasolabial fold, or as otitis externa. Atopic dermatitis is generally diffuse on scalp and almost inevitably present at other sites, but may coexist with tinea capitis, especially in children.
Pityriasis amiantacea	Thick sheets of asbestos-like scale, very adherent, generally a solitary patch. This may occur in various dermatoses.
Lichen simplex	Usually nape of neck; cobblestoned or lichenified skin thickening, with broken hairs that are not coated with scale.
Alopecia areata	Usually not inflamed (may be mildly so), not scaly, usually sharply defined. "Exclamation mark" hairs occur but are not coated with fungus; "cadaverized" hairs especially cause difficulty, as they mimic black dot alopecia.
Scarring alopecias	Examples: Discoid lupus erythematosus, lichen planus of scalp; cause perifollicular inflammation around intact hairs; usually associated with lesions at other sites also. Dissecting cellulitis of scalp is also in this differential.
Bacterial infections	Impetigo causes crusting but little inflammation, and hairs are intact; carbuncle is deeper and very tender but may be in the differential of kerion.
Trichotillomania	Broken hairs of unequal length, but hair shafts themselves and the scalp are normal.
Damage from hairdressing processes	Usually clear from the timescale.
Neoplasm	May be in the differential of kerion; usually slower-growing and mainly on elderly, balding scalp, whereas kerion is in children or young adults with previously intact hair.

From White GM, Cox NH (eds): *Diseases of the skin, a color atlas and text,* ed 2, St Louis, 2006, Mosby.

griseofulvin, 5 to 15 mg/kg PO per day (maximum, 750 mg/day), in one single dose or two divided doses. Optimally, griseofulvin is given after a meal containing fat (e.g., peanut butter or ice cream). Recommended treatment length is 6 to 8 wk and should be continued 2 wk beyond clinical resolution (until hair regrowth occurs). Some children may require higher doses to achieve clinical cure.

2. **Adults and elderly persons:** Microsize griseofulvin 500 mg PO per day in one single dose or divided doses. The other option is ultramicrosize griseofulvin 375 mg PO per day in one single dose or divided doses. Recommended treatment length is 4 to 6 wk.

- Newer alternative treatments: Oral terbinafine, itraconazole, or fluconazole are comparable in efficacy and safety to griseofulvin, with possibly shorter treatment and better patient compliance. Preferred when resistant or when an allergy to griseofulvin is of concern. Monitoring of CBC, liver function tests, and renal function may be indicated.
  1. Terbinafine—4-wk course of therapy as effective as with griseofulvin. Dosages are 67.5 mg/day for patients weighing <20 kg; 125 mg/day for patients weighing 20 to 40 kg; and 250 mg for patients weighing >40 kg
  2. Itraconazole—3.5 mg/kg daily for 4 to 6 wk or pulse therapy of 5 mg/kg daily for 1 wk each mo for 2 to 3 mo (not approved for children)
  3. Fluconazole—the only oral antifungal agent approved for children <2 yr, 6 mg/kg/day for 6 wk in children (3 to 6 wk in adults) or 8 mg/kg weekly for 8 to 12 wk (cap at 150 mg weekly for adults)
- The adjuvant use of antifungal shampoos may be recommended for all patients and household contacts. Shampoo like selenium sulfide 2.5% used for 5 min or ketoconazole shampoo used 2 to 3 times/wk can help prevent infection or eradicate asymptomatic carrier state by inhibiting fungal growth.
- Severe inflammatory kerion can be managed with additional prednisone 40 mg daily (1 mg/kg/day in children) and tapering over 2 wk.
- Prompt treatment is indicated, as is examination of siblings and other household contacts for evidence of tinea capitis.
- Recommend follow-up visit every 2 to 4 wk with Wood's light, microscopic study, and fungal culture. A mycologic documented cure is the goal of treatment.
- Pets that are infected or asymptomatic carriers should be treated.
- Children receiving treatment for tinea capitis may attend school once they start therapy with griseofulvin or other effective systemic agent.

PEARLS & CONSIDERATIONS

- Systemic antifungal therapy is required for tinea capitis because topical antifungal medications are not effective.
- Shaving of the head, haircuts, or wearing a cap or scarf during treatment is unnecessary.
- Sharing of combs, hair ribbons, and hairbrushes should be discouraged.

COMMENTS

- Confirming the diagnosis of tinea capitis with a laboratory specimen is important because misdiagnosis will result in delay or improper treatment.
- Patients and their families should look for sources of infections and disinfect contaminated objects such as combs, brushes, towels, and headgear. Avoid sharing personal hygiene utensils.
- Culture of hairs and scalp dander facilitates carrier identification and prevention.

BASIC INFORMATION

DEFINITION

Tinea corporis is a dermatophyte fungal infection caused by the genera *Trichophyton* or *Microsporum*. Tinea corporis includes all superficial dermatophyte infections of the skin other than those involving the scalp, beard, face, hands, feet, and groin.

SYNONYMS

Ringworm
Body ringworm
Tinea circinata

ICD-10CM CODE
B35.4 Tinea corporis

EPIDEMIOLOGY & DEMOGRAPHICS

- The disease is more common in warm climates.
- There is no predominant age or sex.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typically appears as single (Fig. E1) or multiple annular lesions with an advancing scaly border (Fig. E2); the margin is slightly raised, reddened (Fig. E3), and may be pustular.
- The central area becomes hypopigmented and less scaly as the active border progresses outward, thus the name "ringworm."
- The trunk and legs are primarily involved.
- Pruritus is variable.
- It is important to remember that recent topical corticosteroid use can significantly alter the appearance of the lesions.
- Tinea gladiatorum is a common problem for wrestlers.

ETIOLOGY

Trichophyton rubrum is the most common pathogen. Other common causes in the U.S. are *M. canis* and *T. mentagrophytes*. Table 1 summarizes common dermatophytes that cause tinea corporis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pityriasis rosea
- Erythema multiforme
- Psoriasis
- Cutaneous systemic lupus erythematosus
- Secondary syphilis
- Nummular eczema
- Eczema
- Granuloma annulare
- Lyme disease
- Tinea versicolor
- Contact dermatitis

WORKUP

Diagnosis is usually made on clinical grounds. It can be confirmed by direct visualization under the microscope of a small fragment of the scale using wet mount preparation and potassium hydroxide solution; dermatophytes appear as translucent branching filaments (hyphae) with lines of separation appearing at irregular intervals.

LABORATORY TESTS

- Microscopic examination of hyphae.
- Mycotic culture is usually not necessary.
- Biopsy is indicated only when the diagnosis is uncertain and the patient has not responded to treatment.
- HIV (widespread tinea corporis may be a presenting sign of AIDS).

TREATMENT

NONPHARMACOLOGIC THERAPY

Affected areas should be kept clean and dry.

ACUTE GENERAL Rx

- Various creams are effective; the application area should include normal skin approximately 2 cm beyond the affected area:
  1. Butenafine cream applied qd for 14 days
  2. Terbinafine cream applied bid for 7 to 14 days
  3. Other effective topical agents are sulconazole, miconazole, clotrimazole, ketoconazole, naftifine, ciclopirox olamine, and efinaconazole
- Systemic therapy is reserved for severe cases and is usually given up to 4 wk; commonly used agents:
  1. Fluconazole, 150 mg once a week for 4 wk
  2. Terbinafine, 250 mg qd for 7 to 14 days
  3. Itraconazole, 200 mg/day for 1 wk

DISPOSITION

Majority of cases resolve without sequelae within 3 to 4 wk of therapy.

REFERRAL

Dermatology referral in patients with persistent or recurrent infections

TABLE 1 Common Dermatophytes that Cause Tinea Corporis

Dermatophyte	Clinical Features
Anthropophilic	
Trichophyton rubrum	Commonly harbored by hair follicles; may produce concentric rings; can recur; causative organism in nodular perifolliculitis (Majocchi granuloma) and most common cause of tinea corporis
T. tonsurans	Commonly seen in adults who care for children with tinea capitis caused by this organism
Epidermophyton floccosum	Generally restricted to groin or feet; responsible for eczema marginatum
T. concentricum	Responsible for tinea imbricata; infections typically chronic
T. interdigitale (previously *T. mentagrophytes* var. *interdigitale*)	Causes interdigital tinea pedis, tinea cruris, and onychomycosis
Zoophilic	
T. mentagrophytes (previously *T. mentagrophytes* var. *mentagrophytes*)	May be associated with dermatophytid reaction; causes inflammatory tinea pedis and tinea barbae; associated with exposure to small mammals
Microsporum canis	Associated with pet exposure (cat or dog)
T. verrucosum	May mimic bacterial furunculosis; associated with exposure to cattle
Geophilic	
M. gypseum	Frequently associated with outdoor/occupational exposure; lesions may be inflammatory or bullous

From Bolognia J et al: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

FIG. E1 Tinea corporis. An expanding, erythematous, annular plaque. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E2 Tinea corporis. Multiple annular, erythematous, scaly plaques with hyperpigmentation of the upper back and shoulders of a teenage boy. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E3 Tinea corporis. Multiple annular, erythematous plaques with confluence and a polycyclic configuration occurred in this immunocompromised patient. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

Tinea Cruris PTG

BASIC INFORMATION

DEFINITION

Tinea cruris is a dermatophyte infection of the groin.

SYNONYMS

Jock itch
Groin ringworm
Crotch itch

ICD-10CM CODE
B35.6 Tinea cruris

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common during the summer in adolescent and young adult males.
- Males are affected more frequently than females; however, it has become more common in postpubertal females who are overweight or who often wear tight jeans or pantyhose.
- The infection often coexists with tinea pedis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- It begins as a small erythematous, and scaling or crusted patch that spreads peripherally.
- Erythematous plaques have a half-moon shape and a scaling border.
- The acute inflammation tends to move down the inner thigh (Fig. E1) and usually spares the scrotum; in severe cases the fungus may spread onto the buttocks.
- Itching may be severe.
- Red papules, vesicles, and pustules may be present.
- An important diagnostic sign is the advancing well-defined border with a tendency toward central clearing.

ETIOLOGY

- Dermatophytes of the genera *Trichophyton, Epidermophyton,* and *Microsporum. T. rubrum* and *E. floccosum* are the most common infecting agents. Table 1 summarizes common causative agents of tinea cruris.
- Transmission from direct contact (e.g., infected persons, animals). The patient's feet should be evaluated as a source of infection because tinea cruris is often associated with tinea pedis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Candidal intertrigo
- Psoriasis
- Seborrheic dermatitis
- Erythrasma
- Contact dermatitis
- Tinea versicolor

WORKUP

Diagnosis is based on clinical presentation and demonstration of hyphae microscopically using potassium hydroxide.

LABORATORY TESTS

- Microscopic examination.
- Cultures are generally not necessary.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Keep infected area clean and dry.
- Boxer shorts are preferred to briefs. The reduction of perspiration and enhancement of evaporation from the crural area are necessary prophylactic measures.

ACUTE GENERAL Rx

- Various topical antifungal agents are available:
  1. Butenafine cream, applied qd × 14 days
  2. Terbinafine cream, applied bid × 14 days
- Drying powders (e.g., miconazole nitrate) may be useful in patients with excessive perspiration.
- Oral antifungal therapy is generally reserved for cases unresponsive to topical agents or can be used along with topical agents in severe cases. Effective medications are fluconazole 200 mg qd × 7 days or 150 mg once a wk for 4 wk, terbinafine 250 mg qd × 14 days, or itraconazole 200 mg/day for 7 days.

DISPOSITION

Most cases respond promptly to therapy with complete resolution within 2 to 3 wk.

Tinea Capitis (Related Key Topic)
Tinea Corporis (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

TABLE 1 Tinea Cruris: Common Causative Pathogens

Dermatophyte	Clinical features
Trichophyton rubrum	• Most common cause of tinea cruris • Infection tends to be chronic • Fungus not viable in scale (e.g., on furniture, rugs, linens) for long periods of time • Frequent extension to buttocks, waist, and thighs
Epidermophyton floccosum	• Commonly associated with "epidemics" of tinea cruris in locker rooms or dormitories • Infection is acute (rarely chronic) • Arthroconidia are viable in scale (e.g., on furniture, rugs, linens) for long periods of time • Infection rarely extends beyond groin region • Causative agent of "eczema marginatum" (well demarcated borders with multiple small vesicles or, sometimes, vesiculopustules)
T. mentagrophytes (previously *T. mentagrophytes* var. *mentagrophytes*)	• Infection tends to be more severe and acute, with intense inflammation and pustule formation • May rapidly spread to the trunk and lower extremities, causing a severe inflammatory condition • Often acquired from animal dander

From Bolognia J et al: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

FIG. E1 Dermatophyte infection. A, *Tinea cruris* showing areas of postinflammatory hyperpigmentation and active infection at the border of the lesions. **B,** Histologically, fungal hyphae are localized within a compact stratum corneum layer. **C,** Potassium hydroxide preparation from a scraping showing fungal forms. (**A,** From Callen JP et al: *Color atlas of dermatology,* Philadelphia, 1993, Saunders, p. 318; **B** and **C,**from Elston DM, Ferringer T: *Dermatopathology,* Edinburgh, 2009, Saunders, p. 275.)

BASIC INFORMATION

DEFINITION

Tinea pedis is a dermatophyte infection of the feet.

SYNONYM

Athlete's foot

ICD-10CM CODE
B35.3 Tinea pedis

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common dermatophyte infection
- Increased incidence in hot humid weather; occlusive footwear is a contributing factor
- Occurrence is rare before adolescence
- More common in adult males

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typical presentation is variable and ranges from erythematous scaling plaques and isolated blisters to interdigital maceration (Fig. E1). The four major types of tinea pedis are summarized in Fig. E2.
- The infection usually starts in the interdigital spaces of the foot. Most infections are found in the toe webs or on the soles.
- Fourth or fifth toes are most commonly involved.
- Pruritus is common and is most intense after removal of shoes and socks.
- Infection with *Trichophyton rubrum* often manifests with a "moccasin" distribution affecting the soles and lateral feet.

Tinea pedis caused by *Trichophyton mentagrophytes* (interdigitale) can present with:

- Erythema and desquamation between the toes
- Multilocular bullae involving the thin skin of the plantar arch and along the sides of the feet and heel
- White superficial onychomycosis

ETIOLOGY

- Dermatophyte infection caused by *T. rubrum, Trichophyton mentagrophytes,* or less commonly *Epidermophyton floccosum.*
- There may be an autosomal dominant predisposition to this form of infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Contact dermatitis
- Toe web infection (bacterial or candidal infection)
- Eczema
- Psoriasis
- Keratolysis exfoliativa
- Juvenile plantar dermatosis

WORKUP

- Diagnosis is usually made by clinical observation.
- Laboratory testing, when performed, generally consists of a simple potassium hydroxide preparation with mycologic examination under a light microscope to confirm the presence of dermatophytes.

LABORATORY TESTS

- Microscopic examination of a scale or the roof of a blister with 10% KOH under low or medium power will reveal hyphae.
- Mycologic culture is rarely indicated in the diagnosis of tinea pedis.
- Biopsy is reserved for when the diagnosis remains in question after testing or failure to respond to treatment.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Hyperhidrosis is a predisposing factor for tinea pedis. Keep infected area clean and dry. Aerate feet by using sandals when possible.
- Use 100% cotton socks rather than nylon socks to reduce moisture.
- Areas likely to become infected should be dried completely before being covered with clothes.

ACUTE GENERAL Rx

- Benzylamines: Butenafine HCl 1% cream applied bid for 1 wk or qd for 4 wk is effective in interdigital tinea pedis.
- Allylamines: Terbinafine cream applied bid × 14 days, or naftifine 1% cream applied qd or naftifine gel applied bid for 4 wk produces a significantly high cure rate.
- Imidazoles: Econazole, ketoconazole, miconazole, luliconazole, and clotrimazole cream are also effective agents. Clotrimazole 1% cream is an over-the-counter treatment. It should be applied to affected and surrounding area bid for up to 4 wk.
- Ciclopirox and tolnaftate are other antifungal agents available in cream, suspension, or gel. Tolnaftate is also available as a lotion, spray, or powder.
- When using topical preparations, the application area should include normal skin approximately 2 cm beyond the affected area.
- Areas of maceration can be treated with Burow solution soaks for 10 to 20 min bid followed by foot elevation.
- Oral agents (fluconazole 150 mg once per wk for 4 wk, terbinafine 250 mg/day for 14 days, itraconazole 200 mg bid × 7 days, or griseofulvin 500 to 1000 mg/day for 14 days) can be used in combination with topical agents in resistant cases.

PEARLS & CONSIDERATIONS

- Use of tolnaftate powder (Tinactin) or Zeasorb medicated powder on the feet after bathing may be helpful in preventing recurrent tinea pedis in susceptible persons.
- Combination therapy of antifungal and corticosteroid (clotrimazole/betamethasone [Lotrisone]) should only be used when the diagnosis of fungal infection is confirmed and inflammation is a significant issue.
- Nystatin is not effective and should not be used.

Athlete's Foot (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

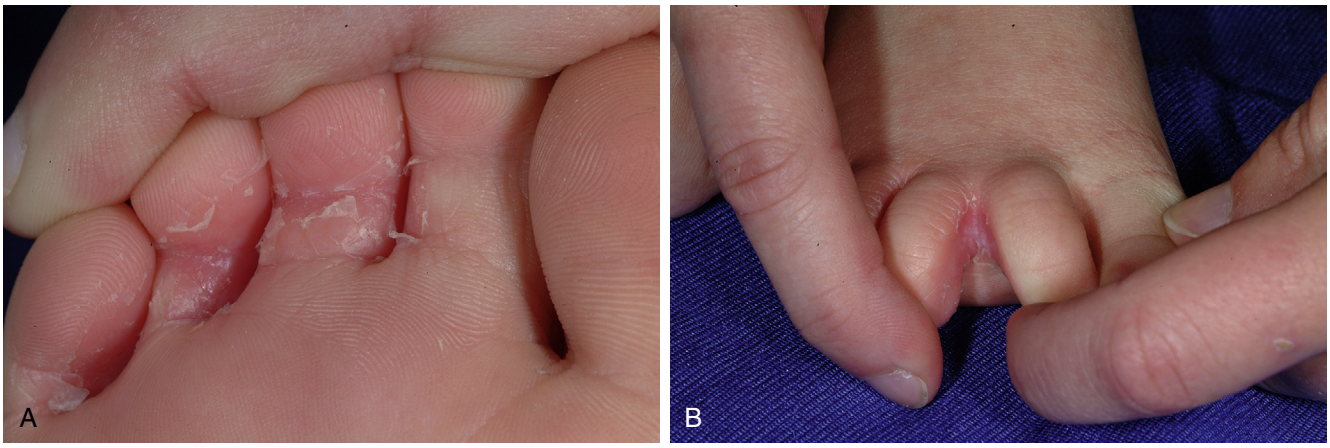

FIG. E1 Tinea pedis. This 6-year-old girl showed erythema and desquamation of the plantar foot and toes **(A)** and toe-web erythema and maceration **(B).** (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

THE FOUR MAJOR TYPES OF "TINEA PEDIS" CAUSED BY DERMATOPHYTES AND NON-DERMATOPHYTES			
Type	**Causative organism**	**Clinical features**	**Treatment considerations**
Moccasin	*Trichophyton rubrum* *Epidermophyton floccosum* *Neoscytalidium hyalinum* *N. dimidiatum*	Diffuse hyperkeratosis, erythema scaling and fissures on one or both plantar surfaces; frequently chronic and difficult to cure;* occasionally associated with immune deficiency	Topical antifungal plus product with urea or lactic acid; may require oral antifungal therapy
Interdigital	*T. interdigitale* (previously *mentagrophytes* var. *interdigitale*) *T. rubrum* *E. floccosum* *N. hyalinum* *N. dimidiatum* *Candida* spp. *Fusarium* spp.	Most common type; erythema, scaling, fissures and maceration in the web spaces; the two lateral web spaces are most commonly affected; "dermatophytosis complex" (fungal infection followed by bacterial invasion†) can develop; pruritus common; may extend to dorsum and sole of foot	Topical antifungal; may require topical or oral antibiotic if superimposed bacterial infection
Inflammatory (vesicular)	*T. mentagrophytes* (previously *T. mentagrophytes* var. *mentagrophytes*)	Vesicles and bullae on the medial foot; often associated with a dermatophytid reaction‡	Topical antifungal usually sufficient
Ulcerative	*T. rubrum* *T. interdigitale* (previously *T. mentagrophytes* var. *interdigitale*) *E. floccosum*	Typically an exacerbation of interdigital tinea pedis; ulcers and erosions in the web spaces; commonly secondarily infected with bacteria; seen in immunocompromised and diabetic patients	Topical antifungal; may require topical or oral antibiotics if secondary bacterial infection (common)

Dermatophytes Non-dermatophytes

*Because of the thickness of stratum corneum on plantar surfaces and the inability of *T. rubrum* to elicit a sufficient immune response to eliminate the fungus.
†Often *Pseudomonas, Proteus* spp., or *Staphylococcus aureus*.
‡Reaction to fungal elements presenting as a dyshidrotic-like eruption on the fingers and palms (culture negative for fungus).

FIG. E2 The four major types of tinea pedis caused by dermatophytes and nondermatophytes. (From Bolognia J et al: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.)

Tinea Unguium PTG

BASIC INFORMATION

DEFINITION

Tinea unguium is defined as a persistent fungal infection affecting the toenails and fingernails.

SYNONYMS

Onychomycosis
Ringworm of the nails

ICD-10CM CODE
B35.1 Tinea unguium

EPIDEMIOLOGY & DEMOGRAPHICS

- Tinea unguium is most commonly found in people between the ages of 40 and 60 yr.
- Tinea unguium rarely occurs before puberty.
- Incidence: 20 to 100 cases/1000 population.
- Toenail infection is 4 to 6 times more common than fingernail infection.
- Tinea unguium affects men more often than women.
- Occurs more frequently in patients with diabetes, peripheral vascular disease, and any conditions resulting in the suppression of the immune system.
- Occlusive footwear, physical exercise followed by communal showering, and incompletely drying the feet predispose the individual to developing tinea unguium.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Tinea unguium causes nails to become thick, brittle, hard, distorted, and discolored (yellow to brown color) (Fig. E1). Eventually, the nail may loosen, separate from the nail bed, and fall off (Fig. E2).
- Tinea unguium is frequently associated with tinea pedis (athlete foot).

ETIOLOGY

- The most common causes of tinea unguium are dermatophyte, yeast, and nondermatophyte molds
- The dermatophyte *Trichophyton rubrum* accounts for 80% of all nail infections caused by fungus
- *Trichophyton interdigitale* and *Trichophyton mentagrophytes* are other fungi causing tinea unguium
- The yeast *Candida albicans* is responsible for 5% of the cases of tinea unguium and tends to involve fingernails more than toenails
- Nondermatophyte molds *Scopulariopsis brevicaulis* and *Aspergillus niger,* although rare, can also cause tinea unguium
- Tinea unguium is classified according to the clinical pattern of nail bed involvement. The main types are:
  1. Distal and lateral subungual tinea unguium (DLSO)
  2. Superficial tinea unguium
  3. Proximal subungual tinea unguium
  4. Endonyx tinea unguium
  5. Total dystrophic tinea unguium

DIAGNOSIS

The diagnosis of tinea unguium is based on the clinical nail findings and confirmed by direct microscopy and culture.

DIFFERENTIAL DIAGNOSIS

- Psoriasis
- Contact dermatitis
- Lichen planus
- Subungual keratosis
- Paronychia
- Infection (e.g., *Pseudomonas*)
- Trauma
- Peripheral vascular disease
- Yellow nail syndrome

WORKUP

The workup of suspected tinea unguium is directed at confirming the diagnosis of tinea unguium by visualizing hyphae under the microscope by KOH prep or by culturing the organism. Although the standard for the diagnosis of fungal nail disease is a positive result on microscopic examination and culture of nail clippings with subungual debris or from surface debris in superficial white tinea unguium, treatment is often prescribed in the absence of confirmatory findings.

LABORATORY TESTS

- KOH prep: Specificity is high but sensitivity is variable.
- Fungal cultures on Sabouraud medium: Culture may take 4 to 6 wk.
- Dermatophyte test medium (DTM): An alternative to Sabouraud that takes only 3 to 7 days and can be done in office setting. A color change indicates dermatophyte growth.
- Nail plate biopsy with periodic acid–Schiff (PAS) stain.
- Blood tests are not specific in the diagnosis of tinea unguium and therefore not useful.

IMAGING STUDIES

- Imaging studies are not very specific in making the diagnosis of tinea unguium and not useful.
- If an infection is present and osteomyelitis is a consideration, an x-ray of the specific area and a bone scan may help establish the diagnosis.

CLASSIFICATION

- The Onychomycosis Severity Index (OSI) is a new classification system for grading the severity of tinea unguium.
- The OSI score is obtained by multiplying the score for the area of involvement (range, 0-5) by the score for the proximity of the disease to the matrix (range, 1-5). Ten points are added for the presence of a longitudinal streak or a patch (dermatophytoma) or for >2 mm of subungual hyperkeratosis.
- Mild tinea unguium corresponds to a score of 1 to 5; moderate to a score of 6 to 15; severe to a score of 16 to 35.
- Indicators of more severe onychomycosis are summarized in Table 1.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Surgical removal of the nail plate is a treatment option; however, the relapse rate is high.
- Prevent reinfection by wearing properly fitted shoes, avoiding public showers, and keeping feet and nails clean and dry.
- Short-pulse laser therapy is fungicidal and is a newer treatment modality for tinea unguium. Most patients will require two to four treatments, each lasting 15 to 30 min. Laser therapy is useful in patients with contraindications to oral agents. It is, however, expensive ($250 to $1000 per treatment) and not covered by most insurance plans.

ACUTE GENERAL Rx

- Topical antifungal creams are used for early superficial nail infections
  1. Miconazole 2% cream applied over the nail plate bid
  2. Clotrimazole 1% cream bid
  3. Ciclopirox: Topical antifungal nail lacquer can be used for moderate tinea unguium that spares the lunula. Success rate <10%.
  4. Efinaconazole 10% topical solution (Jublia) is modestly effective in treating

TABLE 1 Indicators of More Severe Onychomycosis with a Poor Response to Treatment

Nail factors	• Subungual hyperkeratosis >2 mm thick • Significant lateral involvement • Dermatophytoma • >50% involvement of nail bed • Slow nail growth rate • Total dystrophic onychomycosis • Matrix involvement
Patient factors	• Immunosuppression • Peripheral arterial disease • Poorly controlled diabetes mellitus

Adapted from Carney C et al: A new classification system for grading the severity of onychomycosis: Onychomycosis severity index, *Arch Dermatol* 147:1277-1282, 2011. From Bolognia J et al: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

toenail tinea unguium due to *Trichophyton rubrum* and/or *Trichophyton mentagrophytes.* Dosage is 1 drop (2 drops for big toenail) once daily for 48 wk. Cost and formulary are limiting factors with this agent.

5. Tavaborole 5% solution (Kerydin) is an oxaborole antifungal drug approved by the U.S. Food and Drug Administration (FDA) for topical treatment of toenail tinea unguium due to *T. rubrum* or *T. mentagrophytes*. It is applied to affected toenails once daily for 48 wk. It is modestly effective but much more expensive than topical ciclopirox 8% nail lacquer.

- Oral agents:
  1. Terbinafine:
     a. For toenails: 250 mg/day for 3 mo
     b. For fingernails: 250 mg/day for 6 wk
  2. Itraconazole:
     a. For toenails: 200 mg PO daily for 3 mo
     b. For fingernails: 200 mg PO daily for 6 wk
  3. Fluconazole: Not as effective as terbinafine or itraconazole:
     a. For toenails: 150 to 300 mg once weekly for 18 to 26 wk
     b. For fingernails: 150 to 300 mg once weekly for 12 to 16 wk
- All oral agents used for tinea unguium require periodic monitoring of liver function blood tests. Patients should be advised to watch for symptoms of drug-induced hepatitis (anorexia, fatigue, nausea, right upper quadrant pain) while taking these oral antifungal agents. They should stop their medication and contact their physician immediately if symptoms occur
- Itraconazole is contraindicated in patients taking cisapride, astemizole, triazolam, midazolam, and terfenadine. Statins should be discontinued during itraconazole therapy. Itraconazole requires gastric acidity for absorption; patients should be advised not to take oral antacids, H_2 blockers, or proton pump inhibitors while taking itraconazole
- Fluconazole is contraindicated in patients taking cisapride and terfenadine
- Oral antifungal agents should not be initiated during pregnancy

DISPOSITION

- Spontaneous remission of tinea unguium is rare.
- A disease-free toenail is reported to occur in approximately 25% to 50% of patients treated with the oral antifungal agents mentioned previously.

REFERRAL

- Podiatry consultation is indicated in diabetic patients for proper instruction in foot care, footwear, and nail debridement or surgical removal of the toenail.
- Dermatology consultation is indicated in patients refractory to treatment or if another diagnosis is considered (e.g., psoriasis).

PEARLS & CONSIDERATIONS

COMMENTS

- The growth of fungus on an infected nail typically begins at the end of the nail and spreads under the nail plate to infect the nail bed as well.
- Carefully consider the informational insert regarding drug-drug interactions and contraindications before initiating oral antifungal agents.
- Meta-analysis showed cure rates with the oral agents as follows: Terbinafine (about 75%), itraconazole (60% to 65%), and fluconazole (about 50%).

FIG.E1 Distal subungual onychomycosis in a 5-year-old child. Note how heavily infected nails occur adjacent to totally normal nails. Cutting back the big toe's nail plate has revealed the friable subungual debris. This material is the most desirable for culture. (From White GM, Cox NH [eds]: *Diseases of the skin, a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

FIG. E2 Collection of nail for culture. The subungual debris is the most valuable material for culture. After the nail is cut back, a curette may be used. Clippings of the nail may be added to the culture. (From White GM, Cox NH [eds]: *Diseases of the skin, a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

Tinea Versicolor PTG

BASIC INFORMATION

DEFINITION

Tinea versicolor is a fungal infection of the skin caused by the yeast *Pityrosporum orbiculare (Malassezia furfur),* a commensal lipophilic fungus that lives in the hair follicles and stratum corneum.

SYNONYM

Pityriasis versicolor

ICD-10CM CODE
B36.0 Pityriasis versicolor

EPIDEMIOLOGY & DEMOGRAPHICS

- Increased incidence in adolescence and young adulthood
- More common during the summer (hypopigmented lesions are more evident when the skin is tanned)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most lesions begin as multiple small, circular macules of various colors (Fig. E1) on the trunk and upper arms.
- The macules may be darker (Fig. E2) or lighter (Fig. E3) than the surrounding normal skin and will scale with scraping.
- Most frequent site of distribution is trunk.
- Facial lesions are more common in children (forehead is most common facial site).
- Eruption is generally of insidious onset and asymptomatic.
- Lesions may be hyperpigmented in blacks.
- Lesions may be inconspicuous in fair-complexioned individuals, especially during the winter.
- Most patients become aware of the eruption when the involved areas do not tan.
- Mild itching and inflammation around the patches may be present.
- Facial lesions may occur in infants and immunocompromised patients.

ETIOLOGY

The infection is caused by *Malassezia* species (*M. globosa, M. restricta, M. sympodialis, M. furfur, M. obtusa,* and *M. slooffiae*). Factors that favor proliferation are pregnancy, malnutrition, immunosuppression, oral contraceptives, and excess heat and humidity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vitiligo
- Pityriasis alba
- Secondary syphilis
- Pityriasis rosea
- Seborrheic dermatitis
- Postinflammatory hyperpigmentation or hypopigmentation
- Pityriasis rubra pilaris
- Syphilis
- Hansen disease

WORKUP

Diagnosis is based on clinical appearance. The *Malassezia* fungus is easily demonstrated in scraping of the profuse scales that cover the lesions. Identification of hyphae and budding spores ("spaghetti and meatballs" appearance) with microscopy confirms diagnosis.

LABORATORY TESTS

Microscopic examination with potassium hydroxide confirms diagnosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

Sunlight accelerates repigmentation of hypopigmented areas.

ACUTE GENERAL Rx

- Topical treatment: Selenium sulfide 2.5% suspension (Selsun or Exsel) applied daily for 30 min for 7 consecutive days results in a cure rate of 80% to 90%. The scalp can be shampooed monthly with selenium sulfide to reduce scalp colonization.
- Antifungal topical agents (e.g., miconazole, ciclopirox, clotrimazole) are also effective.
- Oral treatment can be given along with topical agents but is generally reserved for resistant cases. Effective agents are fluconazole and itraconazole. Table 1 summarizes treatment options for tinea versicolor.

DISPOSITION

The prognosis is good, with eradication of the fungus usually occurring within 3 to 4 wk of treatment; however, recurrence is common. After initial therapy, use of monthly application of selenium sulfide may lower risk of recurrence.

PEARLS & CONSIDERATIONS

COMMENTS

Patients should be informed that the hypopigmented areas will not disappear immediately after treatment and that several mo may be necessary for the hypopigmented areas to regain their pigmentation.

Tinea Versicolor (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

TABLE 1 Treatment of Tinea (Pityriasis) Versicolor

Initial therapy (often combination)	*Topical**
	• Antifungal shampoo applied as a body cleanser for 10-15 minutes before rinsing, twice weekly for 2-4 wk 1. Selenium sulfide shampoo, 1% (OTC) or 2.5% 2. Ketoconazole shampoo, 1% (OTC) or 2% 3. Zinc pyrithione shampoo 4. Ciclopirox olamine shampoo, 1%
	• Antifungal cream applied several hand-widths beyond clinically visible lesions, daily to twice daily for 2 wk 1. Imidazole, e.g., ketoconazole 2% cream 2. Ciclopirox olamine 0.77% cream, gel, or lotion
	Oral†
	• Fluconazole: 200 mg PO daily × 5-7 days‡; 200-300 mg weekly × 2-3 wk; or 400 mg once • Itraconazole: 200 mg PO daily × 5-7 days
Maintenance therapy to prevent recurrence	• Treat previously affected sites with topical imidazole daily for 2 wk prior to anticipated sun exposure • Apply antifungal shampoo (see earlier) 1-2 times weekly

Oral ketoconazole is no longer indicated for treatment of superficial fungal infections due to risks of severe hepatotoxicity, QT prolongation, and serious drug interactions.
*Treatment of all the skin from the neck down to the knees may lead to higher success rates.
†Although there are few comparative studies of oral antifungal medications, cure rates of 98% to 100% have been reported in several randomized controlled trials of itraconazole 200 mg daily × 5 days and an open-label study of fluconazole 300 mg weekly × 2 wk.
‡Based upon authors' personal experience.

FIG. E1 Tinea versicolor. Hypopigmented, minimally scaly macules and patches of seborrheic areas of the trunk. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E2 Tinea versicolor. This immunosuppressed teenager with inflammatory bowel disease had hyperpigmented (rather than hypopigmented) scaly papules and plaques. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

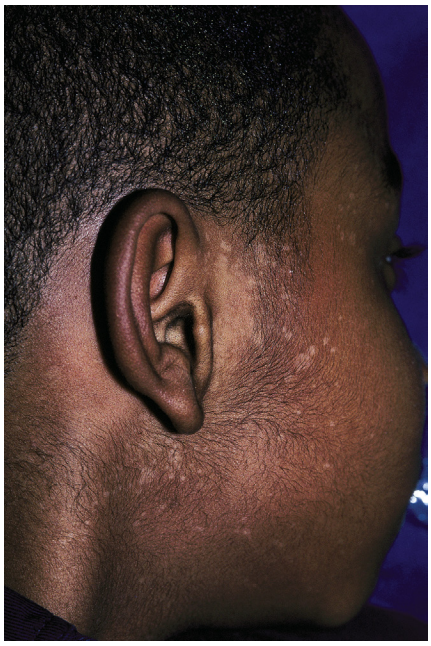

FIG. E3 Tinea versicolor. Occasional involvement of the face and/or neck is noted, especially in darkly pigmented individuals. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

Tinnitus is a perceived sound in the absence of acoustic stimulus external to the head. It may be unilateral, bilateral, or lateral dominant. It is commonly described as a ringing, buzzing, roaring, hissing, whistling, humming, cricket-like, or pulsing sound. It is frequently a symptom associated with hearing loss, Ménière disease, acoustic neuroma, drug toxicity, depression, or an autoimmune inner ear disease. The sound may be internal and perceived only by the patient, called subjective or tonal tinnitus, or it may be heard by both the patient and the examiner, called objective or nontonal tinnitus.

ICD-10CM CODES

H93.1	Tinnitus
H93.2	Other abnormal auditory perceptions
H93.11	Tinnitus, right ear
H93.12	Tinnitus, left ear
H93.13	Tinnitus, bilateral
H93.19	Tinnitus, unspecified ear

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- The American Tinnitus Association reports 50 to 60 million Americans have tinnitus for >6 mo.
- Prevalence increases steadily with age, peaking for persons aged 60 to 69 yr.
- Prevalence in the U.S. based on National Health Interview Survey (NHIS) in 1996:
  1. 2.98% all ages
  2. 0.26% for persons <18 yr old
  3. 1.6% for persons aged 18 to 44 yr
  4. 5.96% for persons aged 45 to 64 yr: 7.7% males, 4.3% females
  5. 9.6% for persons aged 65 to 74 yr: 12% males, 7.7% females
  6. 7.6% for persons >75 yr: 11.4% males, 5.3% females
  7. 2:1 South/Northeast regions
- Up to 18% of people in industrialized societies are mildly affected by chronic tinnitus, and 0.5% report tinnitus having a severe effect on their daily life.
- Only 20% of patients with persistent tinnitus ever seek medical evaluation.

PREDOMINANT SEX AND AGE: Persons most affected are male, Caucasian, elderly, persons with hearing impairment, persons living in southern U.S. For military veterans, tinnitus is the third most common service-related disability.

RISK FACTORS: Any condition causing hearing loss or damage to the auditory system can produce tinnitus. Cochlear damage from exposure to noise is the most common cause. Exposure to ototoxic drugs is also important.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History should focus on exposure to loud noises, evidence of hearing loss, and ototoxic drugs.
- Patient should be screened for depression.
- Patient who complains of sound in ear may also complain of ear pain or fullness.
- Objective tinnitus is pulsatile and coincides with patient's pulse.
- Physical examination should focus on HEENT, neck, and neurologic exam.
- There may be no significant physical findings.

ETIOLOGY

- The mechanism behind tinnitus is poorly understood. It may originate at any point along the auditory pathway. Causes of tinnitus include injured cochlear hair cells, spontaneous activity in auditory nerve fibers, hyperactivity in the auditory nuclei in the brain stem, or a reduction in the suppressive activity of the central auditory cortex.
- Medications implicated in causing tinnitus include salicylates, NSAIDs, aminoglycosides, loop diuretics, valproate, quinine, chemotherapeutic agents, cisplatin, vincristine, and heavy metals such as lead.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Subjective/tonal tinnitus:
  1. Otologic: Tympanic membrane disorder, inner ear disorder (hair cells, organ of Corti), Ménière disease
  2. Ototoxic medications
  3. Neurologic: Multiple sclerosis, head trauma, cochlear nerve lesion, acoustic schwannoma, neurofibroma, meningioma
  4. Metabolic: Thyroid disorder, hyperlipidemia (leading to plaque formation), vitamin B_{12} deficiency
  5. Psychogenic: Depression, anxiety, fibromyalgia
  6. Infectious: Otitis media, Lyme disease, meningitis, syphilis
- Objective/nontonal tinnitus:
  1. Vascular: Arterial bruit, venous hum, arteriovenous malformation, vascular tumors
  2. Neurologic: Contraction of muscles of the eustachian tube, contraction of the stapedius muscle, contraction of the tensor tympani muscles, or a palatal myoclonus, glomus jugulare tumor
  3. Conductive: Patulous (wide-open) eustachian tube

WORKUP

- Audiometry.
- Tympanometry.
- Electronystagmography is used to evaluate for Ménière disease.
- An algorithm for tinnitus evaluation is described in Fig. E1 and Fig. E2.

LABORATORY TESTS

Evaluate for metabolic abnormalities: TSH, CBC, B_{12}, and lipid panel.

IMAGING STUDIES

- CT/MRI: To evaluate for subjective tinnitus
- MRI/MRA: To evaluate objective tinnitus
- Imaging should not be part of routine management. Clinicians must distinguish patients with bothersome tinnitus from patients with nonbothersome tinnitus. For patients without persistent and bothersome tinnitus, audiometric testing is optional.

TREATMENT

NONPHARMACOLOGIC THERAPY

- It is best to avoid exposure to excessive noise, ototoxic agents, and to wear protective equipment in noisy environments, or mask the tinnitus through amplification of normal sounds with a hearing aid. Habituation techniques such as tinnitus retraining therapy may help. Cognitive-behavioral therapy helps patients cope with tinnitus distress through biofeedback.
- Recent trials involving brain stimulation in the form of repetitive transcranial magnetic stimulation (rTMS have shown reduction in the perception or severity of tinnitus).[1]

ACUTE GENERAL Rx

- If the tinnitus is severe enough to cause suicidal symptoms, immediate referral to a psychiatrist and an otolaryngologist is recommended to minimize the time to diagnosis and optimize treatment.
- Patients with persistent symptoms or tinnitus accompanied by visual changes or headache should be evaluated for tumors such as acoustic neuroma.
- Clinicians should not routinely recommend anxiolytics, anticonvulsants, or intratympanic medications.

CHRONIC Rx

There is insufficient evidence to support the use of any medication, vitamin, or nutritional supplement to treat tinnitus. Empirical use of over-the-counter supplements or prescription medications should be discouraged.

DISPOSITION

Clinical course is variable. About 20% to 25% of patients with chronic tinnitus consider it a significant problem. Individualized tinnitus management programs can be beneficial in most patients.

PEARLS & CONSIDERATIONS

PREVENTION

- Avoid loud, chronic noise and ototoxic drugs.
- Higher caffeine intake is associated with a lower risk of incidence of tinnitus in women.

BASIC INFORMATION

DEFINITION

The term *Torsade de Pointes* (TdP) refers to a polymorphic ventricular tachycardia (VT) associated with a prolonged QT interval and electrocardiographically characterized by QRS complexes of changing amplitude that appear to twist around the isoelectric line, hence the name *Torsade de Pointes*, or "twisting of the points" (Fig. 1).

Torsade is typically initiated by a short-long-short sequence of ventricular beats but can also be initiated by a short-coupled variant. Typically, TdP occurs in the setting of a markedly prolonged QT interval (>500 msec); the QTc prolongs even further during the long diastolic interval of a compensatory pause after an early beat, leading to a polymorphic VT with a ventricular rate of 160 to 250 beats per minute, irregular RR intervals, and a cycling of the QRS axis through 180 degrees every 5 to 20 beats. It may be repetitive, nonsustained, or sustained and may degenerate into ventricular fibrillation. In some cases, the result is sudden cardiac death.

SYNONYMS

Torsades
TdP

ICD-10CM CODE
I47.2 Ventricular tachycardia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The precise incidence of TdP is unclear but accounts for fewer than 5% of all sudden cardiac arrests. In congenital long QT syndromes (LQTS), TdP may occur in up to 6% of cases at rest and 9% of cases during an exercise test. Among drug-induced causes of TdP, the incidence may vary between <1% in cases of antibiotics and antipsychotics to 2% to 4% when caused by class III anti-arrhythmics such as sotalol, ibutilide, and dofetilide.

PREDOMINANT SEX AND AGE: Because testosterone shortens the QT interval, women have a longer baseline QT interval, which is believed to be the reason for a two- to threefold increased incidence of TdP in women.

GENETICS: Of the congenital LQTS channelopathies, long QT syndromes 1, 2, and 3 account for >70% of all cases. In general, the risk of TdP increases as the QT lengthens; however, there are also genotype-phenotype relationships that help define risk; for example, LQTS3 carries a higher risk of TdP than LQTS1. Similarly, the Jervell and Lange-Nielsen syndrome and Romano-Ward syndrome may lead to TdP.

It is also likely that genetic factors are at play in acquired LQT and in the development of TdP. For example, in large populations, the QT interval prolongs very little with the administration of QT-prolonging drugs such as fluoroquinolones; however, certain individuals will have markedly exaggerated QT prolongation that leads to TdP; this is likely due to some underlying genetic factor.

RISK FACTORS: TdP in patients with congenital LQTS is often initiated by an external trigger (Table 1). Triggers can include exercise, noise, emotion, sudden waking from sleep by an alarm clock, telephone ringing, thunder, swimming, or diving. TdP in LQT1 patients is classically triggered by vigorous exercise or swimming; in LQT2 by emotion, pregnancy, or noise; and in LQT3 when at rest or asleep. Risk factors for drug-induced TdP are outlined in Table 2.

The risk factors for developing TdP in patients with acquired long QT are extensive and are outlined in Table 3.

PATHOPHYSIOLOGY:

- Changes in the balance of transmembrane ionic currents lead to lengthening of the QT interval and to abnormal action potentials called early afterdepolarizations (EADs). An EAD, in the setting of electrical instability induced by the prolonged QT, initiates the torsades. Perpetuation may be caused by transmural entry, triggered activity, or abnormal automaticity. A distinct group of cells called the M cells, located in the mid-myocardium, has a less rapid delayed rectifier potassium current (IKr), and these cells are central to the genesis of TdP.
- Drugs with the potential to cause TdP most frequently inhibit the rapid potassium channels and result in prolongation of the action potential duration, producing a prolonged QT on ECG.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical features depend on whether the TdP is caused by acquired or congenital long QT syndrome. Congenital LQTS patients may have certain specific triggers, such as noise, exercise, and emotions (see "Risk Factors").
- Symptoms of the tachycardia itself include palpitations, pre-syncope, syncope (sometimes with jerking movements from myoclonus, often misinterpreted as seizures), and sudden cardiac death (SCD).
- Patients resuscitated from SCD have an especially ominous prognosis, with a relative risk of 12.9% of experiencing another cardiac arrest.

ETIOLOGY

The etiology or triggers of TdP may be congenital or acquired causes of QT prolongation (see Table 1). For a comprehensive list of drugs that can cause or have the potential to cause TdP, see "Patient/Family Education."

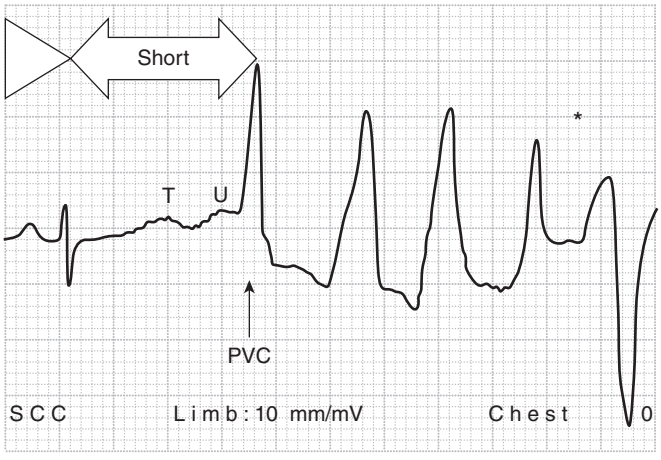

FIG. 1 Onset of Torsade de Pointes during the recording of a standard 12-lead electrocardiogram (ECG) in a young male with a history of drug addiction treated with chronic methadone therapy who presented to a hospital emergency department after ingesting an overdose of prescription and over-the-counter drugs from his parent's drug cabinet. Classic ECG features evident in this rhythm strip include a prolonged QT interval with distorted T-U complex, initiation of the arrhythmia after a short-long-short cycle sequence by a PVC that falls near the peak of the distorted T-U complex, "warm-up" phenomenon with initial R-R cycles longer than subsequent cycles, and abrupt switching of QRS morphology from predominantly positive to predominantly negative complexes (asterisk). (From Drew BJ et al: Prevention of Torsade de Pointes in hospital settings: a scientific statement from the American Heart Association and the American College of Cardiology Foundation, *J Am Coll Cardiol* 55:934-947, 2010.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of syncope:

- Other causes of broad complex tachycardia such as:
  1. Polymorphic VT
  2. Wolff-Parkinson-White (WPW) syndrome with rapid atrial fibrillation
  3. ECG artifact

WORKUP

- ECG (Fig. 2) and telemetry are the mainstays of diagnosing TdP as they detect the arrhythmia, the preceding prolonged QT interval, and the long-short cycles that trigger it.
- Determination and treatment of the etiology of TdP (see Table 1) is key.

TABLE 1 Causes and Triggers of Torsade de Pointes

Congenital	
	• Romano-Ward syndrome (autosomal dominant)
	• Jervell and Lange-Nielsen syndrome (autosomal recessive)
	• LQTS channelopathies
Acquired	
Metabolic syndromes	• Hypokalemia
	• Hypocalcemia
	• Hypomagnesemia
	• Starvation
	• Anorexia nervosa
	• Liquid protein diets
	• Hypothyroidism
Bradyarrhythmias	• Sinus node dysfunction
	• Second- or third-degree AV block
Antiarrhythmic drugs	• Quinidine
	• Procainamide
	• Disopyramide
	• Amiodarone and dronedarone
	• Sotalol
	• Dofetilide, ibutilide, azimilide
Antimicrobial drugs	• Erythromycin, clarithromycin, azithromycin
	• Pentamidine
	• Azole antifungals like voriconazole
	• Fluoroquinolones such as levofloxacin and moxifloxacin
	• Chloroquine
Antihistaminics	• Terfenadine
	• Astemizole
Psychiatric drugs	• Phenothiazines
	• Thioridazine
	• Tricyclic antidepressants
	• Haloperidol
	• Risperidone
	• Selective serotonin reuptake inhibitors
Antineoplastic agents	• Tyrosine kinase inhibitors such as sunitinib, dasatinib
	• Vorinostat
	• Arsenic
Gastric motility agents	• Cisapride, domperidone
Opioid dependence drugs	• Methadone
Other factors	• Myocardial ischemia
	• Hypothermia
	• Intracranial disease
	• HIV infection
	• Connective tissue disease with anti-Ro/SSA antibodies
	• Periodic paralysis (Andersen syndrome)
	• Cocaine

LABORATORY TESTS

- Electrolytes: Assess for hypokalemia, hypocalcemia, and hypomagnesemia
- Thyroid function tests
- Genetic studies if suspicion of congenital LQT syndrome

IMAGING STUDIES

- Echocardiography to rule out structural heart disease as a cause of VT
- Stress test to rule out myocardial ischemia. Stress ECG with dynamic assessment of the QT interval during varying heart rates may be diagnostic of long QT syndromes and related TdP
- CT scan of the head if intracranial disease is suspected

Rx TREATMENT

The cornerstone of treatment comprises intravenous magnesium and acceleration of the heart rate, either by mechanical overdrive pacing or by infusion of isoproterenol. Withdrawal of causative drugs and correction of underlying causes such as electrolyte imbalances, hypothermia, and ischemia are also important.

NONPHARMACOLOGIC THERAPY

- Withdrawal of any offending drugs and correction of electrolyte abnormalities are recommended in patients presenting with TdP (Class I recommendation).
- Temporary atrial or ventricular overdrive pacing is a Class I recommendation for all causes of TdP if intravenous magnesium fails.
- Acute and long-term pacing is recommended for patients presenting with TdP due to heart block and symptomatic bradycardia (Class 1) or those with recurrent pause-dependent torsades (Class IIa).
- Active internal and external rewarming if hypothermia is the etiology.

TABLE 2 Risk Factors for Drug-induced Torsade de Pointes

- Congenital long QT
- Female gender
- Electrolyte abnormalities (hypokalemia, hypomagnesemia, hypocalcemia)
- Diuretic use
- Bradycardia
- Cardiac hypertrophy
- Myocardial fibrosis
- Congestive heart failure
- Renal and liver insufficiency
- Coadministration of drugs blocking P450 isoenzyme CYP3A4
- High doses or rapid intravenous infusion of the drug
- Baseline electrocardiographic abnormalities (prolonged QT, T-wave lability)

From Gowda RM et al: Torsades de Pointes: the clinical considerations, *Int J Cardiol* 96(1):1-6, 2004.

TABLE 3 Risk Factors for Torsade de Pointes in Hospitalized Patients

- Clinically recognizable risk factors
- QTc >500 msec
- LQT2-type repolarization: Notched or "bifid" T-wave
- Use of QT-prolonging drugs
- Concurrent use of more than one QT-prolonging drug
- Rapid infusion by intravenous route
- Structural heart disease
- Congestive heart failure
- Myocardial infarction
- Advanced age
- Female sex
- Hypokalemia
- Hypomagnesemia
- Hypocalcemia
- Treatment with diuretics
- Impaired hepatic drug metabolism
- Bradycardia
- Sinus bradycardia, heart block, incomplete heart block with pauses
- Premature QRS complexes leading to short-long-short cycles
- Multiple clinically recognizable risk factors
- Occult (latent) congenital LQTS
- Genetic polymorphisms

From Drew BJ et al: Prevention of Torsade de Pointes in hospital settings: a scientific statement from the American Heart Association and the American College of Cardiology Foundation, *Circulation* 121(8):1047, 2010.

- If TdP degenerates into ventricular fibrillation, defibrillation and advanced cardiac life support protocol should be followed.

ACUTE GENERAL Rx

- Intravenous magnesium sulfate 1 to 2 g given over 1 to 2 min is first-line therapy for patients who present with LQTS and few episodes of TdP (Class IIa). Magnesium is not likely to be effective in patients with a normal QT interval.
- Isoproterenol is reasonable as temporary treatment in patients with acute disease who present with recurrent pause-dependent TdP

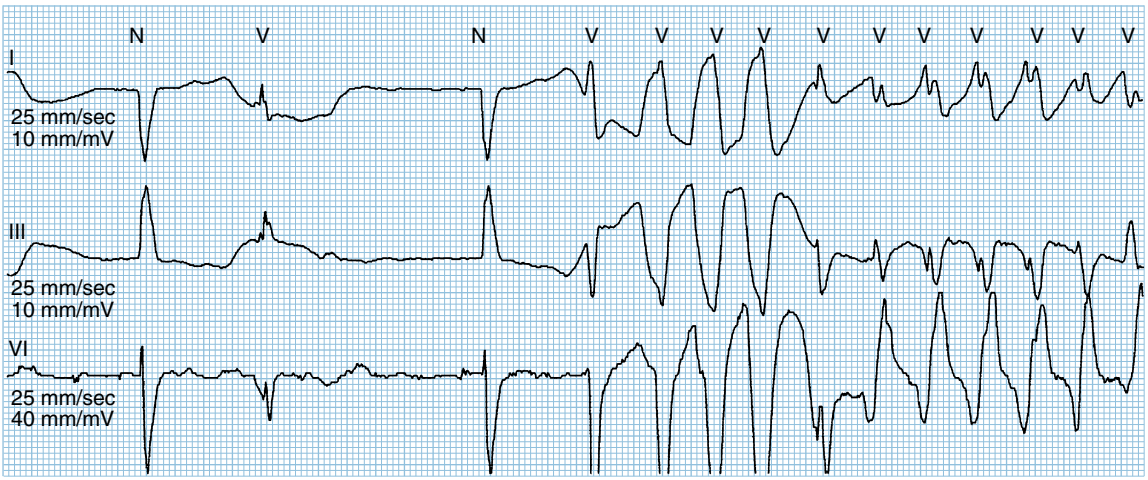

FIG. 2 Torsade de Pointes. This lead I, III, and V_1 rhythm strip shows sinus bradycardia with left bundle branch block and marked QT prolongation with premature ventricular contractions (R-on-T) that initiates a very rapid polymorphic ventricular tachycardia with the characteristic twisting of the QRS complex around the isoelectric baseline. Torsade de Pointes literally means "twisting of the points." (From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

and who do not have congenital LQTS (Class IIa).
- Beta-blockade combined with pacing is reasonable acute therapy for patients who present with TdP and sinus bradycardia (Class IIa).
- Potassium repletion to 4.5 to 5 mmol/L may be considered for patients who present with TdP and hypokalemia (Class IIb).
- Intravenous lidocaine, oral mexiletine, or phenytoin may be considered in patients who present with LQT3 and TdP (Class IIb).
- TdP is usually self-limited, and cardioversion should be performed only as a last resort in the setting of pulseless VF because of the high likelihood of immediate recurrence of the TdP after cardioversion.

CHRONIC Rx

- TdP resulting from congenital LQTS is treated with beta-blockade (propranolol or nadolol are preferred), pacing, and implantable cardioverter-defibrillator (ICD) in high-risk cases. For patients who continue to have syncope despite maximal drug therapy, cervical-thoracic sympathectomy may be considered.
- Long-term pacing is recommended for patients presenting with TdP due to heart block and symptomatic bradycardia.
- Avoid use of QT-prolonging drugs.
- Lifestyle modification in case of congenital LQTS.
- In patients with eating disorders, nutritional rehabilitation will correct the QT prolongation over the long term (3-18 mo).
- Psychiatric evaluation of patients with drug overdose and eating disorders.

DISPOSITION

Patients with TdP should be monitored in an intensive care setting.

REFERRAL

Patients should have an urgent cardiology consultation.

PEARLS & CONSIDERATIONS

COMMENTS

- Identification of the etiology for TdP is key in diagnosis, management, and prognosis of this condition.
- Drugs associated with TdP vary greatly in their risk for arrhythmia; an updated list can be found at https://crediblemeds.org. The risk-benefit ratio should be assessed for each individual to determine whether the potential therapeutic benefit of a drug outweighs the risk for TdP.
- Risk factors for drug-induced TdP include older age, female sex, heart disease, electrolyte disorders (especially hypokalemia and hypomagnesemia), renal or hepatic dysfunction, bradycardia or rhythms with long pauses, treatment with more than one QT-prolonging drug, and genetic predisposition.
- After initiation of a drug associated with TdP, ECG signs indicative of risk for arrhythmia include an increase in QTc from predrug baseline of >60 msec, marked QTc interval prolongation >500 msec, T-U wave distortion that becomes more exaggerated in the beat after a pause, visible T-wave alternans, new-onset ventricular ectopy, and couplets and nonsustained polymorphic ventricular tachycardia initiated in the beat after a pause.

PREVENTION

The 2011 AHA/ACC scientific statement on prevention of TdP suggests a strategy of documenting the QTc interval before and at least every 8 to 12 hr after the initiation, increased dose, or overdose of QT-prolonging drugs. If QTc prolongation is observed, documentation of more frequent measurements is recommended. The duration of QTc monitoring depends upon the duration of treatment with the QT-prolonging drug and the drug half-life.

PATIENT & FAMILY EDUCATION

- Patients should be educated about avoiding use of QT-prolonging drugs. A complete list of these drugs can be found at https://crediblemeds.org.
- First-degree relatives of all patients with congenital LQTS should undergo genetic testing.
- Congenital LQTS patients should avoid certain specific triggers (e.g., swimming and exercise in LQTS 1 and LQTS 2 and acoustic stimuli in LQTS 2).
- It is recommended that all patients affected by LQTS avoid competitive sports activity.

Long QT Syndrome (Related Key Topic)

AUTHOR: **Christopher Pickett, MD**

BASIC INFORMATION

DEFINITION

The most common definition of torticollis is the contraction or contracture of the muscles of the neck that causes the head to be tilted to one side (Fig. E1). It is often accompanied by rotation of the chin to the opposite side with flexion. Usually torticollis is a symptom of some underlying disorder. Torticollis can also be defined as posttraumatic or inflammatory in cases of fixed positional disorders of the head and neck.

SYNONYMS

Twisted neck
"Wry neck"
Spasmodic torticollis
Grisel syndrome
Posttraumatic painful torticollis (posttraumatic cervical dystonia)
Cervical dystonia

ICD-10CM CODES

G24.3	Spasmodic torticollis
M43.6	Torticollis
Q68.0	Congenital deformity of sternocleidomastoid muscle

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Congenital muscular torticollis:
  1. Palpable soft tissue "mass" in the sternocleidomastoid shortly after birth
  2. Mass gradually subsides, leaving a shortened, contracted sternocleidomastoid muscle
  3. Head characteristically tilted toward the side of the mass and rotated in the opposite direction
  4. Facial asymmetry and other secondary changes persisting into adulthood
- Spasmodic torticollis:
  1. "Spasms" in the cervical musculature; may be bilateral and uncontrollable
  2. Head often tilted toward the affected side
- Grisel syndrome:
  1. Painful nontraumatic subluxation of the atlanto-axial joint from inflammatory ligamentous laxity from an infectious process in the head or neck
  2. Often presents associated with recent upper respiratory tract infection or retropharyngeal abscess
  3. Rare postoperative complication after head and neck surgery (e.g., adenotonsillectomy)
- Posttraumatic painful torticollis:
  1. Abnormal posturing of the head after local injury to the neck or cervical spine; also known as posttraumatic cervical dystonia (PTCD)
  2. Severe pain with abnormal fixed posture of the head
  3. Presents after trauma, commonly motor vehicle crashes and falls from height
  4. May have an associated psychological component
- Findings in other cases depend on etiology. In *cervical dystonia*, the most frequent focal dystonia, one or more neck muscles involuntarily contract to rotate or tilt the head and neck (Fig. E2). The resultant posture may consist of turning of the head to one side (torticollis), tilting to one side (laterocollis), flexion (anterocollis), or extension (retrocollis); most often these occur in complex combinations. The movements initially occur intermittently, but as the condition progresses, the abnormal postures become sustained and a superimposed "dystonic tremor" often complicates the picture. Unlike other forms of dystonia, cervical dystonia causes pain because the muscle contractions forcefully compress and rotate the cervical vertebra on each other and irritate the cervical nerve roots that emerge between them.

ETIOLOGY

Torticollis has been found to have more than 50 different causes:

- Localized fibrous shortening of unknown cause involving the sternocleidomastoid, leading to the condition termed *congenital muscular torticollis*
- Spasmodic torticollis: Of uncertain etiology, possibly a variant of dystonia musculorum deformans
- Infection, specifically pharyngitis, tonsillitis, retropharyngeal abscess
- Miscellaneous rare causes: Congenital musculoskeletal deformities, trauma, inflammation from rheumatoid arthritis, vestibular disturbances, posterior fossa tumor, syringomyelia, neuritis of spinal accessory nerve, and drug reactions

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Table E1 summarizes the differential diagnosis of torticollis.

WORKUP

- Workup depends on the clinical situation.
- Laboratory studies are usually not helpful unless infection or rheumatoid disease is suspected.
- Any child with a gradually increasing torticollis should have a complete eye examination.

IMAGING STUDIES

- Plain radiographs in cases of trauma or to rule out congenital abnormalities
- MRI in appropriate cases
- Electrodiagnostic studies: Only rarely indicated to rule out neurologic causes
- US can be used to define neck masses in suspected congenital muscular torticollis

FIG. E1 Cervical dystonia consists of neck muscle contraction that causes rotation (torticollis), tilting (laterocollis), flexion (anterocollis), or extension (retrocollis)—usually in combination—of the head and neck. Shoulder elevation often accompanies the other movements. Continuous contractions result in muscle hypertrophy and pain. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

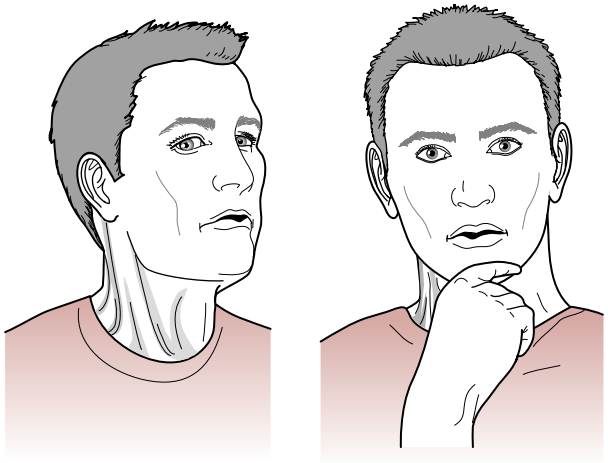

FIG. E2 As with blepharospasm and other focal dystonias, patients with cervical dystonia instinctively learn sensory tricks such as lightly touching the chin, which is a classic *geste antagoniste.* (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

TABLE E1 Differential Diagnosis of Torticollis

Congenital
- Muscular torticollis
- Positional deformation
- Hemivertebra (cervical spine)
- Unilateral atlanto-occipital fusion
- Klippel-Feil syndrome
- Unilateral absence of sternocleidomastoid
- Pterygium colli

Trauma
- Muscular injury (cervical muscles)
- Atlanto-occipital subluxation
- Atlantoaxial subluxation
- C2-3 subluxation
- Rotary subluxation
- Fractures

Inflammation
- Cervical lymphadenitis
- Retropharyngeal abscess
- Cervical vertebral osteomyelitis
- Rheumatoid arthritis
- Grisel syndrome (nontraumatic subluxation of the atlantoaxial joint due to local inflammation)
- Upper lobe pneumonia

Neurologic
- Visual disturbances (nystagmus, superior oblique or lateral rectus paresis)
- Dystonic drug reactions (phenothiazines, haloperidol, metoclopramide)
- Cervical cord tumor
- Posterior fossa brain tumor
- Syringomyelia
- Wilson disease
- Dystonia musculorum deformans

Other
- Acute cervical disk calcification
- Sandifer syndrome (gastroesophageal reflux, hiatal hernia)
- Benign paroxysmal torticollis
- Bone tumors (eosinophilic granuloma)
- Soft tissue tumor
- Psychogenic

From Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

Rx TREATMENT

- Congenital muscular torticollis: Gentle stretching exercises carried out by the parent; surgical release can benefit fixed deformities or those associated with secondary cervicothoracic scoliosis
- Spasmodic torticollis: Physical therapy, psychotherapy, cervical braces, biofeedback, and pain control
- Focal dystonia responds well to injections of botulinum toxin type A or B
- Grisel syndrome: Treatment of the underlying inflammatory process
- Posttraumatic painful torticollis: Treatment of psychological component, physical therapy, treatment of any initially unrecognized injury
- Other forms: Treated according to etiology

DISPOSITION

- Most patients with congenital muscular torticollis respond well to conservative treatment.
- Spasmodic torticollis is often resistant to normal conservative treatment.
- Prognosis of other forms of torticollis depends on etiology.

REFERRAL

- Torticollis often requires a multidisciplinary approach unless the etiology is obvious.
- Children usually do not require any specific studies; however, an orthopedic consultation is recommended.
- Fixed deformity in the child; may need orthopedic referral for surgical release.

BASIC INFORMATION

DEFINITION

Tourette syndrome (TS) is an inherited neuropsychiatric disorder characterized by motor, vocal, and phonic tics that change during the course of illness. Onset of symptoms is typically before the age of 18.

Tics are sudden, brief, intermittent, involuntary or semi-voluntary movements (motor tics), or sounds (phonic or vocal tics) that mimic fragments of normal behavior.

SYNONYMS

Gilles de la Tourette syndrome
TS
Tourette disorder

ICD-10CM CODE

F95.2 Combined vocal and multiple motor tic disorder [de la Tourette]

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE (IN U.S.): Unknown; estimates range from 0.3% to 0.9% in children
PREDOMINANT SEX: Approximate male:female ratio of 4:1
PREDOMINANT AGE: Typical age of onset is between 2 and 15 yr (mean 5 to 7 yr).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Neurologic examination is normal.
- Vocal and phonic tics are characterized as simple (e.g., clearing of throat, sniffing, grunting, sucking) or complex (e.g., repetition of short phrases, swearing [coprolalia]).
- Motor tics can be simple (e.g., blinking, grimacing, head jerking [Fig. 1]) or complex (e.g., gesturing [Fig. 2]). Tics wax, wane, change over time, and are often suppressed for short periods. Commonly, they are preceded by an urge to perform the tic.
- TS is often associated with a variety of behavioral symptoms, most commonly attention deficit hyperactivity disorder (ADHD) and obsessive-compulsive disorder (OCD).

TS can be diagnosed using the DSM-5 criteria as follows:

- Both multiple motor and one or more vocal tics must be present at some time during the illness, although not necessarily concurrently.
- The tics may wax and wane in frequency but have persisted for more than 1 yr since first tic onset.
- Age at onset is less than 18 yr.
- Disturbance is not attributable to the direct physiologic effects of a substance (e.g., stimulants) or another medical condition (e.g., Huntington disease or postviral encephalitis).

ETIOLOGY

The exact pathogenesis is unknown. Genetic predisposition is likely as there is a strong family history of OCD or TS in patients with tics, and twin studies provide evidence for the importance of genetic factors. Recent analysis of linkage in a two-generation pedigree has led to the identification of a mutation in the HDC gene encoding l-histidine decarboxylase, the rate-limiting enzyme in histamine biosynthesis, pointing to a role for histaminergic neurotransmission in the mechanism and modulation of TS and tics. Immunologic dysfunction is also being explored in the pathogenesis of this complex disorder.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Sydenham chorea: Occurs after infection with group A *Streptococcus.*
- Pediatric autoimmune neuropsychiatric disorder associated with group A streptococci (PANDAS).
- Sporadic tic disorders: Tics tend to be motor or vocal but not both.
- Head trauma.
- Drug intoxication: Many drugs are known to induce or exacerbate tic disorders, including methylphenidate, amphetamines, anticholinergics, and antihistamines.
- Postinfectious encephalitis.
- Inherited disorders: Huntington disease, neurodegeneration with brain iron accumulation, and neuroacanthocytosis. These conditions should have other observed abnormalities on neurologic examination.

WORKUP

Clinical observation and history to confirm diagnosis

LABORATORY TESTS

No definitive laboratory tests

IMAGING STUDIES

CT scan and MRI of brain are unremarkable in TS and unnecessary if the neurologic examination is within normal limits.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Multidisciplinary: Education of parents, teachers, psychologists, and school nurses is essential.
- Watchful waiting without intervention is an appropriate treatment if tics are not bothersome, since the natural history of tics is to improve with time. 60% of patients have minimal or no tics 6 yr after initial diagnosis.
- Cognitive behavioral therapy, termed habit-reversal treatment or Comprehensive Behavioral Intervention for Tics (CBIT), is efficacious in suppressing tics and is the first-line treatment.
- Screening for ADHD, OCD, and depression on a regular basis is important.

ACUTE GENERAL Rx

Dopamine-blocking agents may be used to acutely reduce the severity of tics. However, these agents carry a risk of side effects, such as acute dystonic reactions.

CHRONIC Rx

Tics only require long-term treatment when they interfere with an individual's psychosocial, educational, and occupational function.

TICS:

- Alpha-2 agonists, such as clonidine and guanfacine, are used for treatment of motor tics and are considered by some experts

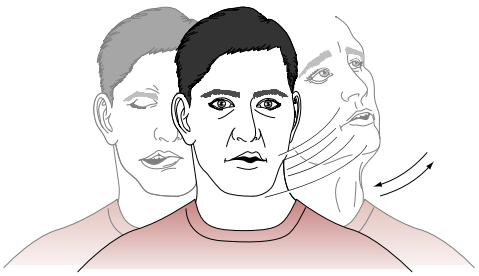

FIG. 1 This young man with Tourette disorder has multiple motor tics, including head jerking (head toss), grimacing of the right side of his mouth (half-smile), and depression of his forehead (frowning). Vocal tics of throat clearing and a short blowing sound accompany his motor tics. All of his tics continue throughout the day and briefly during sleep. Conversation, eating, and social situations have little influence, but with effort he can suppress his tics for several minutes. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

FIG. 2 This woman has compulsive obscene gestures—copropraxia. Similar to coprolalia, they have no affective or sexual content. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

as first-line medications after behavioral therapy because of their favorable adverse effect profile. However, they are more beneficial for treatment of behavioral symptoms and are preferred for patients with predominant psychiatric disorders.

- Haloperidol and pimozide are the only U.S. Food and Drug Administration-approved neuroleptics for the treatment of tics in TS. Pimozide is started at a dose of 0.5 to 1.0 mg at night and increased every 5 to 7 days to a therapeutic dose of 2 to 8 mg. Haloperidol is started at a dose of 0.25 to 0.5 mg and can be increased to 1 to 4 mg depending on response and side effects. Use of neuroleptics carries a small but significant risk of tardive dyskinesia.
- Tetrabenazine is a dopamine-depleting agent that can be used effectively in TS patients to control tics. Tetrabenazine does not cause many of the typical side effects of neuroleptic medication. However, severe depression may occur with use of tetrabenazine. Newer deutetrabenazine and valbenazine (VMAT2 inhibitors) also can be considered and have randomized placebo-controlled trials in progress.
- Topiramate is an antiepileptic used off-label to treat tics.
- Botulinum toxin (local injection) is effective for focal tics like eye blinking and neck and shoulder tics. The benefits are temporary, lasting 3 to 6 mo.
- Surgical treatment with deep brain stimulation is effective in some patients with disabling tics that are refractory to medications.

ADHD: Stimulants are useful for symptoms of ADHD but may exacerbate tics in 25% of patients. These medications should be used if troublesome behavioral symptoms persist.

OCD: Selective serotonin reuptake inhibitors, such as fluoxetine, are the most effective treatment for OCD.

DISPOSITION

- The intensity and frequency of tics typically diminishes during the later teenage years.
- One third of patients will achieve significant remission, although complete, lifelong remission is rare.
- One third will have mild, persistent, but "non-impairing" tics.

REFERRAL

Neurologist to confirm the initial diagnosis and for treatment in difficult cases

PEARLS & CONSIDERATIONS

- Tics do not need treatment unless they interfere with an individual's ability to function.
- Greater improvement in symptom severity among children with TS and chronic tic disorder has been reported with a comprehensive behavioral intervention compared with supportive therapy and education.
- An important part of treatment is appropriate evaluation and therapy of coexisting conditions (e.g., ADHD, OCD), as these conditions often cause more disability than the tics themselves.
- Deep brain stimulation has shown promising results as an alternative therapy in patients with medically refractory disease.

COMMENTS

Patient education may be obtained from the Tourette Syndrome Association, 4240 Bell Blvd., Bayside, NY 11361-2864; 800-237-0717 or 718-224-2999; http://www.tsa-usa.org.

Toxic Epidermal Necrolysis

BASIC INFORMATION

DEFINITION

Toxic epidermal necrolysis (TEN) is a rare, acute, life-threatening mucocutaneous disease that is characterized by whole epidermal keratinocyte death resulting in dermal-epidermal separation of more than 30% body surface area (BSA). TEN and Steven-Johnson Syndrome (SJS) were initially described as separate entities, but are now considered to be variants of the same spectrum of disease, with similar clinical, histopathologic, and pathogenic features. SJS involves less than 10% BSA, SJS-TEN overlap involves 10% to 30% BSA, and TEN involves more than 30% BSA. TEN and SJS are caused by a hypersensitivity reaction to medications.

SYNONYM

Lyell syndrome

ICD-10CM CODE
L51.2 Toxic epidermal necrolysis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Annual incidence is two to seven cases per million per year
PREDOMINANT SEX AND AGE: Women:men ratio 1.5:1
GENETICS: Some ethnic groups are more susceptible to developing TEN to certain medications when having specific human leukocyte antigen (HLA) alleles: e.g., to carbamazepine in Asians and East Indians with HLA-B*1502 and Europeans with HLA-A*3101, or to allopurinol in Han Chinese with HLA-B*5801.
RISK FACTORS: Slow acetylator genotypes, immunosuppression, and concomitant administrations of radiotherapy and anticonvulsants increase the risk for TEN.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The lesions in TEN are dynamic and follow a sequence of changes characterized below.

- *Early*: Fever, stinging eyes, pain upon swallowing may precede cutaneous manifestations by 2 to 7 days.
- *Later*: Generalized, dusky red, purpuric macules of irregular size and shape, with tendency to coalesce (Fig. E1). Nikolsky sign positive (top layers of the skin slip away from the lower layers when slightly rubbed), detachment of large sheets of necrotic epidermis, extreme skin pain, mucosal involvement, anxiety, and asthenia. As the necrotic epidermis detaches from the underlying dermis, flaccid blisters form. The blisters can be extended sideways by slight pressure with a finger as more necrotic epidermis is displaced laterally (Asboe–Hansen sign). TEN patients resemble burn victims clinically, as well as in morbidity and mortality.
- *Resolution:* Scarring may develop when healing (joint contractures, eye complications, strictures of esophagus, anus, vagina, urethra).

ETIOLOGY

Exfoliation of the epidermis is due to extensive keratinocyte apoptosis. Several mechanisms have been postulated to explain the keratinocyte apoptosis. These include drug- or cytotoxic T-cell–mediated expression of FasL, perforin, granulysin, and granzyme B by keratinocytes via a molecular bridge involving tumor necrosis factor alpha (TNF-α), interferon gamma (IFN-γ), and inducible nitric oxide synthase (iNOS).

Medications most commonly associated with the development of TEN are shown in Table E1. Medications other than those listed in Table E1 have been classified to carry a lower risk, a doubtful risk, or being without evidence for a risk to induce TEN (see "Suggested Readings").

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Steven-Johnson syndrome +SJS/TEN overlap
- Erythema multiforme-major (mostly postinfectious)
- Staphylococcal scalded skin syndrome
- Generalized fixed drug eruptions
- Paraneoplastic pemphigus
- Drug-induced linear IgA bullous dermatosis

WORKUP

Identification of TEN is based on the clinical findings of epidermal detachment of more than 30% BSA, mucous membrane involvement, and full-thickness epidermal necrolysis, as described by pathology. A complete medication history should be taken including a time line outlining when new medications were started before the onset of the clinical symptoms. TEN most commonly occurs between 1 and 4 wk after starting a new drug, but can occur at any time. Risk assessment should be done by using the SCORTEN mortality prognostic indicator (see Table E2). Workup for the patient is similar to burn patients.

FIG. E1 Toxic epidermal necrolysis. (Courtesy David Effron, MD. From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, WB Saunders.)

TABLE E1 Medications Most Commonly Causing Toxic Epidermal Necrolysis

Allopurinol	Cotrimoxazole
Sulfa drugs	Aminopenicillins
Carbamazepine	Cephalosporins
Phenobarbital	Quinolones
Phenytoin	Minocycline
Phenylbutazone	Trimethoprim-sulfamethoxazole
Lamotrigine	
Nevirapine	Amithiozone (thioacetazone)
Oxicam NSAIDs	Antiretroviral drugs, especially NNRTIs
Thioacetazone	

NNRTIs, Non-nucleoside reverse transcriptase inhibitors; *NSAIDs,* nonsteroidal antiinflammatory drugs.

TABLE E2 SCORTEN Mortality Prognostic Indicator

Prognostic Factor	Points	SCORTEN	Mortality (%)
Age >40 yr	1	0-1	3.2
Heart rate >120 bpm	1	2	12.1
Cancer/hematologic malignancy	1	3	35.8
BSA involved more than 10% on day 1	1	4	58.3
Serum urea level >28 mg/dl	1	>5	90
Serum bicarbonate level <20 mEq/L	1		
Serum glucose level >252 mg/dl	1		

BSA, Body surface area; *SCORTEN,* SCORe of Toxic Epidermal Necrosis.

LABORATORY TESTS

In addition to the skin biopsy, no specific laboratory test is available to diagnose TEN. Standard chemistry to monitor electrolyte and fluid balance and organ function (e.g., serum urea, bicarbonate, glucose; see Table E2) should be monitored as in burn patients.

IMAGING STUDIES

N/A

TREATMENT

Withdrawing the offending drug reduces the risk of death by 30% per day and is the single most important measure in the management of TEN.

NONPHARMACOLOGIC THERAPY

- *Symptomatic treatment:*
  1. SCORTEN >1: Transfer to intensive care unit/burn unit
  2. Fluid replacement
  3. Peripheral venous access (preferably in non-involved areas)
  4. Increased environmental temperature (30°C; 86° F)
  5. Air-fluidized bed
  6. Early nutritional support through nasogastric tube
  7. Aseptic procedures, frequent culturing of skin, blood, urine specimens
  8. No prophylactic antibiotics
  9. Prophylactic anticoagulation
  10. Nonadhesive wound dressings, porcine xenografts, human allografts, autologous skin grafts, skin substitutes
  11. Daily ophthalmologic exam/consultation; artificial tears, antibiotic eyedrops every 2 hours; early mechanical disruption of synechia
  12. Regular mouth washes with antiseptic/antifungal solutions

ACUTE GENERAL Rx

There is no consensus for the optimal pharmacologic treatment of TEN.

- High-dose steroids may be effective in the initial course of the disease, but probably increase mortality later on due to infectious complications (sepsis).
- Administration of high-dose IVIG over 3 to 4 days may reduce TEN-associated mortality (e.g., by blocking Fas-FasL interaction).
- Newer studies have found that cyclosporine offers a greater mortality benefit and decreases morbidity because the mean duration of re-epithelialization and duration of hospital stay was significantly lower (e.g., by targeting granulysin).
- Several reports in the literature suggest efficacy of TNF-α inhibitors, notably infliximab and etanercept.
- Other agents that may also be effective in the treatment of TEN include cyclophosphamide, plasmapheresis, and N-acetylcysteine.

DISPOSITION

Late withdrawal of the causative drug is associated with a less favorable outcome/increased mortality. If he/she survives, the patient may suffer debilitating and disfiguring scars and contractures, requiring extensive physical therapy and/or surgical interventions.

PEARLS & CONSIDERATIONS

COMMENTS

Early recognition and prompt discontinuation of the culprit drug saves lives.

PREVENTION

In order to prevent recurrences, it is of pivotal importance that patients are never again exposed to the drug that caused TEN. This also includes chemically related medications. Avoiding any drugs that have caused less severe drug reactions in the past is important for primary prevention of TEN.

BASIC INFORMATION

DEFINITION

Toxic megacolon is a rare but severe complication of colonic inflammation, usually inflammatory bowel disease (IBD). It is characterized by total or segmental nonobstructive colonic distention (>6 cm) associated with systemic toxicity of inflammatory or infectious etiology.

SYNONYM

Toxic dilation of the colon

ICD-10CM CODES

A04.7 Megacolon due to *Clostridium difficile*
K59.3 Megacolon, not elsewhere classified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Varies depending on etiology. Incidence in patients with ulcerative colitis (UC) is approximately 10% and nearly 5% in patients with Crohn disease. *Clostridium difficile* infections may be complicated by toxic megacolon in up to 3% of cases.
PEAK INCIDENCE: N/A
PREVALENCE: N/A
PREDOMINANT SEX AND AGE: With increasing rates of *Clostridium difficile (C. diff)* infections, patients ages 65 and older are at higher risk for developing toxic megacolon as a result of *C. diff* infection.
GENETICS: There are no known genetic factors that predispose patients to developing toxic megacolon associated with an inflammatory or infectious etiology.
RISK FACTORS: Major risk factors include inflammatory, infectious, and ischemic conditions of the colon, especially in individuals who are immunocompromised. Other risk factors include hypokalemia, use of narcotics or antidiarrheal agents, pregnancy, and recent instrumentation (such as colonoscopy).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with toxic megacolon usually appear severely ill. Clinical symptoms are similar to those of IBD and acute colitis and may include abdominal pain, diarrhea (usually bloody) and vomiting.
- Physical exam findings may include a distended, tender, and tympanic abdomen with reduced or absent bowel sounds. The patient may also present with signs of shock such as fever, tachycardia, mental status changes, and hypovolemia. Older patients are less likely to demonstrate a peritoneal abdominal examination.
- Laboratory findings may include leukocytosis, lactic acidosis, anemia, and electrolyte abnormalities such as hypokalemia and hypoalbuminemia.

ETIOLOGY

- Most common etiologies are inflammatory conditions such as UC, Crohn disease, and Behçet disease.
- Infections such as *C. diff, Salmonella, Shigella, E. coli,* cytomegalovirus, and *Entamoeba* can also be complicated by toxic megacolon.
- Other less common etiologies include ischemic colitis, malignancy such as lymphoma, and Kaposi sarcoma. In general, toxic megacolon is more likely to be associated with pancolitis than segmental colitis (Box 1).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Ischemic colitis, Crohn disease, ulcerative colitis

WORKUP

- General principles of workup include physical examination to evaluate for an acute abdomen, laboratory testing and radiography to evaluate for colonic dilation.
- Clinical criteria for toxic megacolon, proposed by Jalan et al in 1969, are still used. A diagnosis can be made if radiographic evidence of colonic distention >6 cm is present with at least three of the following: Fever >38° C (100.4° F), heart rate >120, leukocytosis >10.5, or anemia. In addition, at least one of the following must also be present: Dehydration, altered level of consciousness, electrolyte abnormalities, or hypotension.
- Patients with suspected toxic megacolon should be triaged emergently to an emergent care setting to facilitate rapid diagnosis and treatment.

LABORATORY TESTS

Initial testing should include a CBC, full chemistry panel, lactic acid, coagulation panel, liver function panel, and a type and screen.

IMAGING STUDIES

- All patients should initially receive a plain abdominal radiograph (Fig. 1) to assess for colonic dilation. Common findings include mucosal irregularity, loss of haustrations, "thumb printing" due to bowel wall edema, and thickening of the colonic wall with a continuous segment of air-filled colon >6 cm in diameter. The transverse or right colon is usually the most dilated segment seen.
- Computed tomography (CT) has been increasingly used to assess disease extent and for surgical planning (Fig. 2). It can also be helpful when differentiating between the various etiologies of toxic megacolon and to assess for complications such as intraabdominal hemorrhage or abscess.

BOX 1 Disorders Associated with Toxic Megacolon

- Inflammatory bowel disease
  1. Ulcerative colitis
  2. Crohn disease
- Infectious colitis
  1. *Salmonella, Shigella*, amoebic colitis
  2. *Clostridium difficile*
  3. Cytomegalovirus colitis
  4. HIV infection
- Cancer chemotherapy
- Ischemia

HIV, Human immunodeficiency virus.
From Vincent JL et al: *Textbook of critical care*, ed 6, Philadelphia, 2011, WB Saunders.

TREATMENT

Treatment includes both medical and surgical options. Principles of initial management include treating the underlying cause, managing shock, analgesia, and early surgical and gastroenterology consultation.

NONPHARMACOLOGIC THERAPY

- Surgery may be required in up to 50% of patients with toxic megacolon who do not show clinical improvement within 24 to 48 hr. The preferred first-line surgical treatment is subtotal colectomy with an end ileostomy. Other options include total proctocolectomy or colon decompression via the Turnbull method.
- Timing of surgical treatment is still controversial, with many advocating for aggressive medical treatment and observation before surgical intervention. Definitive indications for early surgical treatment include perforation, persistent colonic hemorrhage, or rapid clinical deterioration.

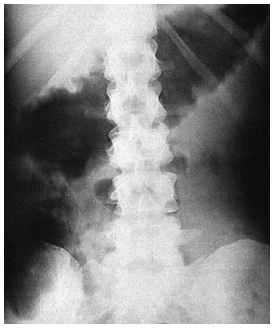

FIG. 1 Toxic megacolon secondary to ulcerative colitis. The smooth indentations seen along the margin of the colon represent pseudopolyps. (From Marx JA et al [eds]: *Rosen's emergency medicine: concepts and clinical practice,* ed 7, Philadelphia, 2010, Elsevier.)

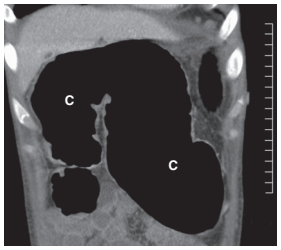

FIG. 2 Toxic megacolon. In a young patient with severe ulcerative colitis, coronal computed tomography demonstrates marked dilation of the colon *(c)* with thinning of its walls. The diameter of the lumen of the colon exceeds 7 cm. This finding places the patient at high risk of colon perforation. (From Webb WR et al: *Fundamentals of body CT,* ed 4, Philadelphia, 2015, WB Saunders.)

ACUTE GENERAL Rx

- Medications that impact colonic motility such as anticholinergics, opioids, and antidiarrheal agents should be discontinued and avoided.
- Electrolyte abnormalities, dehydration, and anemia are common clinical findings and should be addressed early. Fluid resuscitation with an isotonic solution and correction of electrolyte disturbances (especially hypokalemia) can help prevent worsening atony of the colonic wall. Patients with anemia from colonic hemorrhage should receive blood transfusion(s).
- Patients with toxic megacolon should receive broad-spectrum antibiotics as soon as possible. Infections due to *C. diff* should be treated with vancomycin (oral or rectal) or metronidazole (oral or IV). Toxic megacolon due to cytomegalovirus should be treated with ganciclovir IV.
- Patients with inflammatory etiologies such as UC or Crohn should receive high-dose IV steroids, either hydrocortisone 100 mg IV or methylprednisolone 60 mg IV. Steroids should not be used in patients with a confirmed infectious etiology.
- There are currently no data to support empiric treatment of toxic megacolon due to IBD with cyclosporine or infliximab. These treatment options should be reserved for patients who are not steroid responsive and should be limited to one attempt at clinical improvement so as not to delay surgical intervention.
- A management algorithm for toxic megacolon is outlined in Fig. 3.

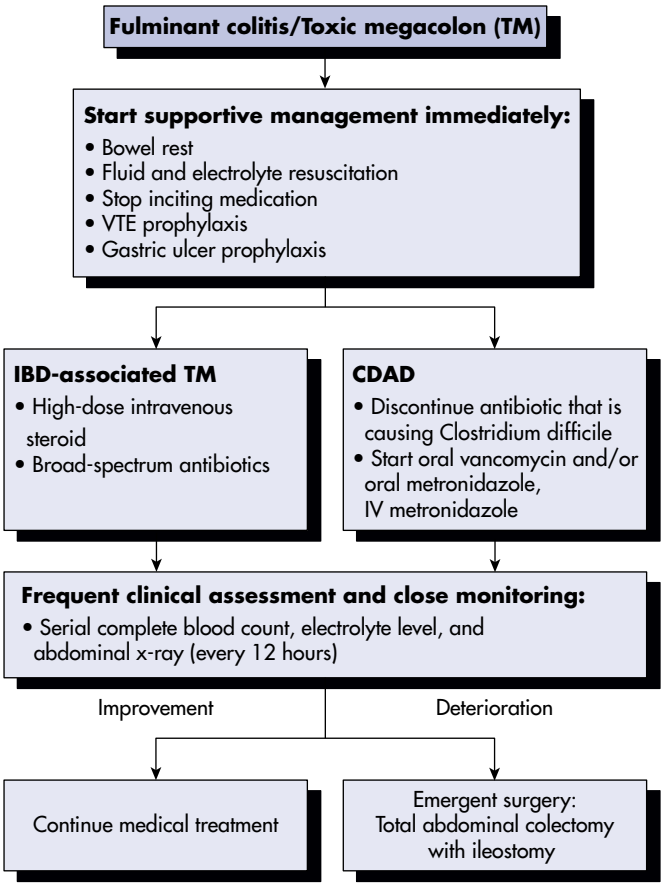

FIG. 3 Management algorithm for toxic megacolon. *CDAD, C. difficile*-associated disease; *IBD,* inflammatory bowel disease; *VTE,* venous thromboembolism. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

CHRONIC Rx

Patients with IBD will need continued treatment for the underlying disease process once the acute processes associated with toxic megacolon have resolved.

COMPLEMENTARY & ALTERNATIVE MEDICINE

N/A

DISPOSITION

All patients with toxic megacolon will require admission, possibly to the intensive care unit, depending on their clinical presentation.

REFERRAL

- Patients with suspected toxic megacolon presenting outside an emergency department should be referred there immediately.
- Surgical consultation in all cases.
- All patients with toxic megacolon due to newly diagnosed IBD who are discharged from the hospital should be referred to a gastroenterologist for continued treatment.

PEARLS & CONSIDERATIONS

COMMENTS

- Early recognition and treatment of toxic megacolon is critical given the associated high morbidity and mortality.
- Anticholinergic medications, antidiarrheal agents, and opioids can precipitate or worsen toxic megacolon.
- Management includes medical and surgical treatment with inpatient hospitalization and treatment of the underlying cause.

PREVENTION

Prevention focuses on treatment of underlying causes of colitis to prevent complications such as toxic megacolon.

BASIC INFORMATION

DEFINITION

Toxic shock syndrome (TSS) is an acute febrile illness resulting in multiple organ system dysfunction caused most commonly by a bacterial exotoxin. Disease characteristics also include hypotension, vomiting, myalgia, watery diarrhea, vascular collapse, and an erythematous sunburn-like cutaneous rash that desquamates during recovery. Box 1 summarizes the clinical case definition of toxic shock syndrome.

SYNONYM

TSS

ICD-10CM CODE
A48.3 Toxic shock syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- Case reported incidence peak: 14 cases per 100,000 menstruating women annually in 1980; has since fallen to 1 case per 100,000 persons
- Occurs most commonly between ages 10 and 30 yr in healthy, young, menstruating white females
- Case fatality ratio of 3%

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fever (>38.0° C; 100.4° F)
- Diffuse macular erythrodermatous rash that involves both skin and mucous membranes, resembles sunburn, and also involves the palms and soles. The rash then desquamates 1 to 2 wk after disease onset in survivors
- Orthostatic hypotension
- Gastrointestinal symptoms: Vomiting, diarrhea, abdominal tenderness
- Constitutional symptoms: Myalgia, headache, photophobia, rigors, altered sensorium, conjunctivitis, arthralgia
- Respiratory symptoms: Dysphagia, pharyngeal hyperemia, strawberry tongue
- Genitourinary symptoms: Vaginal discharge, vaginal hyperemia, adnexal tenderness
- End-organ failure
- Severe hypotension and acute renal failure
- Hepatic failure
- Cardiovascular symptoms: Disseminated intravascular coagulation, pulmonary edema, acute respiratory distress syndrome (ARDS), endomyocarditis, heart block

ETIOLOGY

- Menstruation-associated TSS: 45% of cases associated with tampons, diaphragm, or vaginal sponge use. There has been a decline in these cases and in the case-fatality ratio.
- Non–menstruation-associated TSS: 55% of cases associated with puerperal sepsis, post-cesarean section endometritis, mastitis, sinusitis, wound or skin infection, septorhinoplasty (nasal packings), pelvic inflammatory disease, respiratory infections following influenza, enterocolitis, and burns. The number of cases is increasing and the case-fatality ratio has not declined.
- Causative agent: *Staphylococcus aureus* infection of a susceptible individual (10% of population lacking sufficient levels of antitoxin antibodies), which liberates the disease mediator TSST-1 (exotoxin). While most cases are caused by methicillin-susceptible *S. aureus* (MSSA), cases of TSS from methicillin-resistant *S. aureus* (MRSA) have occurred, particularly those due to the more virulent, community-associated MRSA strains.
- *S. aureus* exotoxins are superantigens that can activate large numbers of T cells (up to 20% at one time), resulting in a massive cytokine production: Interleukin (Il-1), Il-2, TNF, and interferon gamma that then mediate the signs and symptoms of the disease.
- Other causative agents: Coagulase-negative staphylococci producing enterotoxins B or C, and exotoxin A–producing group A beta-hemolytic streptococci.
- Risk factors for staphylococcal toxic shock syndrome are summarized in Box 2.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Staphylococcal food poisoning
- Septic shock
- Mucocutaneous lymph node syndrome
- Scarlet fever
- Rocky Mountain spotted fever
- Meningococcemia
- Toxic epidermal necrolysis
- Kawasaki syndrome
- Leptospirosis
- Legionnaires' disease
- Hemolytic-uremic syndrome
- Stevens-Johnson syndrome
- Scalded skin syndrome
- Erythema multiforme
- Acute rheumatic fever

WORKUP

Broad-spectrum syndrome with multiorgan system involvement and variable but acute clinical presentation, including the following diagnostic criteria for staphylococcal toxic shock syndrome:

- Fever (>38° C; 100.4° F)
- Classic desquamating rash (1 to 2 wk)
- Hypotension/orthostatic systolic blood pressure ≤90 mm Hg
- Syncope
- Negative throat and cerebrospinal fluid cultures
- Negative serologic test for Rocky Mountain spotted fever, rubeola, and leptospirosis
- Clinical involvement of three or more of the following:
  1. Cardiopulmonary: ARDS, pulmonary edema, endomyocarditis, second- or third-degree atrioventricular block
  2. Central nervous system: Altered sensorium without focal neurologic findings
  3. Hematologic: Thrombocytopenia (platelets <100,000)
  4. Liver: Elevated liver function test results

BOX 1 Clinical Case Definition of Toxic Shock Syndrome

Clinical Findings

- Fever: Temperature of ≥38.9° C (102° F)
- Rash: Diffuse macular erythroderma
- Desquamation: 1 to 2 weeks after onset of illness, particularly on palms, soles, fingers, and toes
- Hypotension: Systolic blood pressure ≤90 mm Hg for adults; <5th percentile by age for children <16 years; orthostatic drop in diastolic blood pressure of ≥15 mm Hg from lying to sitting; orthostatic syncope or orthostatic dizziness
- Involvement of three or more of the following organ systems:
  - Gastrointestinal: Vomiting or diarrhea at onset of illness
  - Muscular: Severe myalgia or creatinine phosphokinase level greater than twice the upper limit of normal for the laboratory
  - Mucous membrane: Vaginal, oropharyngeal, or conjunctival hyperemia
  - Renal: Blood urea nitrogen or serum creatinine greater than twice the upper limit of normal, or 5 or more white blood cells per high-power field in the absence of a urinary tract infection
  - Hepatic: Total bilirubin, aspartate transaminase, or alanine transaminase greater than twice the upper limit of normal for the laboratory
  - Hematologic: Platelets <100,000/mm^2
  - Central nervous system: Disorientation or alterations in consciousness without focal neurologic signs when fever and hypotension are absent
- Negative results on the following tests, if obtained:
  - Blood, throat, or cerebrospinal fluid cultures; blood culture may be positive for *Staphylococcus aureus*
  - Serologic tests for Rocky Mountain spotted fever, leptospirosis, or measles

Case Classification

- *Probable:* A case with 5 of the 6 clinical findings above
- *Confirmed:* A case with all 6 of the clinical findings above, including desquamation, unless the patient dies before desquamation can occur

From Wharton M et al: Case definitions for public health surveillance, *MMWR Recomm Rep* 39[RR-13]:1-43, 1990. In Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.

BOX 2 Risk Factors for Staphylococcal Toxic Shock Syndrome

I. Colonization of infection with toxin-producing *Staphylococcus aureus*
II. Absence of protective antitoxin antibody
III. Infected site
  A. Primary *S. aureus* infection:
    - Carbuncle
    - Cellulitis
    - Dental abscess
    - Empyema
    - Endocarditis
    - Folliculitis
    - Mastitis
    - Osteomyelitis
    - Peritonitis
    - Peritonsillar abscess
    - Pneumonia
    - Pyarthrosis
    - Pyomyositis
    - Sinusitis
    - Tracheitis
  B. Postsurgical wound infection:
    - Abdominal
    - Breast
    - Cesarean section
    - Dermatologic
    - Ear, nose, and throat
    - Genitourinary
    - Neurosurgery
    - Orthopedic
  C. Skin or mucous membrane disruption:
    - Burns (chemical, scald, etc.)
    - Dermatitis
    - Influenza
    - Pharyngitis
    - Postpartum (vaginal delivery)
    - Superficial/penetrating trauma (insect bite, needle stick)
    - Viral infection
    - Varicella
  D. Foreign body placement:
    - Augmentation mammoplasty
    - Catheters
    - Contraceptive sponge
    - Diaphragm
    - Surgical prostheses, stents, packing material, sutures
    - Tampons
  E. No obvious focus of infection (vaginal or pharyngeal colonization)

Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

5. Renal: >5 cells/high-power field, negative urine cultures, azotemia, and increased creatinine (double normal)
6. Mucous membrane involvement: Vagina, oropharynx, conjunctiva
7. Musculoskeletal: Myalgia, creatine phosphokinase twice normal
8. Gastrointestinal: Vomiting, diarrhea

For streptococcal toxic shock syndrome the diagnostic criteria is as follows:

- Definite case: Isolation of group A β-hemolytic streptococci (GABHS) from a sterile site
- Probable case: Isolation of GABHS from a nonsterile site
- Hypotension: Presence of two of the following findings:
  1. Acute kidney injury or failure
  2. Elevated aminotransferase
  3. Erythematous macular rash, soft tissue necrosis
  4. Coagulopathy, including thrombocytopenia and disseminated intravascular coagulation
  5. Acute respiratory distress syndrome

TABLE 1 Staphylococcal Versus Streptococcal Toxic Shock Syndrome

Feature	Staphylococcal	Streptococcal
Age	Primarily 15-35 yr	Primarily 20-50 yr
Gender	Higher frequency in women	Men and women equally affected
Severe pain	Rare	Common
Hypotension	100%	100%
Erythroderma rash	Very common	Less common
Renal failure	Common	Common
Bacteremia	Low frequency	60%
Tissue necrosis	Rare	Common
Predisposing factors	Tampons, surgery	Cuts, burns, varicella
Thrombocytopenia	Common	Common
Mortality rate	<3%	30%-70%

From Mandell GL et al: *Principles and practice in infectious diseases,* ed 7, Philadelphia, 2008, Churchill Livingstone.

BOX 3 Therapeutic Principles for Management of Toxic Shock Syndrome

1. Identify the focus of infection; debride and irrigate extensively and remove any foreign material
2. Isolate the organism for antimicrobial susceptibility studies
3. Administer parenteral antimicrobial therapy to stop toxin production and eradicate the organism
4. Manage systemic multiorgan actions of toxins or mediators
5. Administer fluid therapy to maintain adequate venous return and cardiac filling pressure and prevent end-organ damage
6. Consider intravenous immunoglobulin for the following:
   - Disease refractory to initial fluid replacement and vasopressor support
   - A focus of infection that cannot be drained

Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

LABORATORY TESTS

- Pan culture (cervix and vagina, throat, nasal passages, urine, blood, cerebrospinal fluid, wound) for *Staphylococcus, Streptococcus* (Table 1), and other pathogenic organisms
- Electrolytes to detect hypokalemia, hyponatremia
- Complete blood count with differential and clotting profile for anemia (normocytic or normochromic), thrombocytopenia, leukocytosis, coagulopathy, and bacteremia
- Chemistry profile to detect decreased protein, increased aspartate aminotransferase, increased alanine aminotransferase, hypocalcemia, elevated blood urea nitrogen and creatinine, hypophosphatemia, increased lactate dehydrogenase, increased creatine phosphokinase
- Urinalysis to detect white blood cells (>5 cells/high-power field), proteinemia, microhematuria
- Arterial blood gases to assess respiratory function and acid-base status
- Serologic tests considered for Rocky Mountain spotted fever, rubeola, and leptospirosis

IMAGING STUDIES

- Chest x-ray to evaluate pulmonary edema
- ECG to evaluate arrhythmia
- Sonography, CT scan, or MRI considered if pelvic abscess or tuboovarian abscess suspected

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Therapeutic principles for management of toxic shock syndrome are outlined in Box 3.
- For optimal outcome: High index of suspicion and early and aggressive supportive management in an ICU setting
- Aggressive fluid resuscitation (maintenance of circulating volume, cardiac output, systolic blood pressure)
- Thorough search for a localized infection or nidus: Incision and drainage, debridement, removal of tampon or vaginal sponge
- Central hemodynamic monitoring, Swan-Ganz catheter, and arterial line for surveillance of hemodynamic status and response to therapy
- Foley catheter to monitor hourly urine output
- Possible military anti-shock trousers as temporary measure
- Acute ventilator management if severe respiratory compromise

- Renal dialysis for severe renal impairment
- Surgical intervention for indicated conditions (i.e., ruptured tubo-ovarian abscess, wound abscess, mastitis)
- Hyperbaric oxygen treatment can be used adjunctively

ACUTE GENERAL Rx

- Isotonic crystalloid (normal saline solution) for volume replacement following "7-3" rule (refers to the response in millimeters of mercury [mm Hg] of the pulmonary artery wedge pressure to volume replacement).
- Electrolyte replacement (K^+, C^+).
- Packed red blood cells, coagulation factor replacement, fresh frozen plasma to treat anemia or dilation and curettage.
- Vasopressor therapy for hypotension refractory to fluid volume replacement (e.g., dopamine beginning at 2 to 5 μg/kg/min).
- Steroids have been used but are not generally recommended due to lack of evidence of benefit.
- It is not clear whether antibiotics alter the course of acute TSS. Most authors recommend that patients receive 10 to 14 days of combination antibiotic therapy. In staphylococcal TSS, effective agents are clindamycin (900 mg IV every 8 hr in adults or 25 to 40 mg/kg per day in children) plus vancomycin (adults: 30 mg/kg per day IV in two divided doses; children: 40 mg/kg per day IV in four divided doses). Oxacillin or nafcillin sodium (2 g IV every 4 hr in adults; children: 100 to 150 mg/kg per 24 hr divided in four doses) can be used instead of vancomycin if TSS is due to MSSA. An alternative to vancomycin is linezolid.
- In streptococcal TSS, effective agents are penicillin G 24 million units/day in divided doses *plus* clindamycin 900 mg IV q8h. Alternative agents are ceftriaxone 2 g IV q24h *plus* clindamycin 900 mg IV q8h.
- Broad-spectrum antibiotic including gram-negative coverage added if concurrent sepsis suspected with TSS.
- Intravenous immune globulin (IVIG): While no controlled trials exist, most authors recommend IVIG (400 mg/kg in a single dose administered over several hours) in severe cases of TSS that are not responding to fluids or vasopressors. It may neutralize superantigen and decrease tissue damage.
- Tetracycline added if considering Rocky Mountain spotted fever.

CHRONIC Rx

- Severely ill patient: May require prolonged hospitalization and supportive management with gradual recovery and/or sequelae from severe end-organ involvement (ARDS or renal failure requiring dialysis)
- Majority of patients: Complete recovery
- Early-onset complications (within 2 wk):
  1. Skin desquamation
  2. Impaired digit sensation
  3. Denuded tongue
  4. Vocal cord paralysis
  5. Acute tubular necrosis
  6. ARDS
- Late-onset complications (after 8 wk):
  1. Nail splitting and loss
  2. Alopecia
  3. Central nervous system sequelae
  4. Renal impairment
  5. Cardiac dysfunction
- Recurrent TSS:
  1. More common in menstruation-related cases.
  2. Less common in patients treated with beta-lactamase–resistant antistaphylococcal antibiotics.
  3. Patients with history of TSS: If suspect signs and symptoms occur, have high index of suspicion and low threshold for evaluation and treatment.
  4. Screen for nasal carriage of *S. aureus* in patients with *S. aureus* TSS and treat with mupirocin in those with positive cultures.

PREVENTION

- Avoidance of tampons or use of low-absorbency tampons only (<4 hr in situ) and alternate with napkins
- Education for patients concerning signs and symptoms of TSS
- Avoidance of tampons for patients with history of TSS

DISPOSITION

- Complete recovery for most patients
- Long-term management of early- and late-onset complications for minority of patients

REFERRAL

- For multidisciplinary management, involving primary physician, gynecologist, internist, infectious disease specialist, and other supportive care specialists
- To tertiary-level hospital

PEARLS & CONSIDERATIONS

COMMENTS

Antibiotic prophylaxis against invasive group A streptococcal infection with benzathine penicillin G plus rifampin, clindamycin, or azithromycin is recommended for immunocompromised household contacts of patients with streptococcal TSS-like syndrome.

BASIC INFORMATION

DEFINITION

Toxoplasmosis is an infection caused by the protozoal parasite *Toxoplasma gondii* transmitted through ingestion of undercooked meat, undercooked shellfish, or cat feces.

ICD-10CM CODES

B58.9	Toxoplasmosis, unspecified
B58.3	Pulmonary toxoplasmosis
B58.89	Toxoplasmosis with other organ involvement
P37.1	Congenital toxoplasmosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Seroprevalence varies widely between different geographic locations, increasing with age, prevalence of cats in the area, and certain activities such as working in slaughterhouses or owning cats.
- Seroprevalence among women of childbearing age was 9.1% between 2009 and 2010.
- 0.23 cases of congenital toxoplasmosis per 10,000 live births between 2006 and 2014.
- Among patients with HIV, seroprevalence is approximately 11% in the U.S.

PREDOMINANT SEX: Equal gender distribution

PREDOMINANT AGE:

- Infancy (congenital infection)
- Prevalence increases with age

PEAK INCIDENCE: Seroprevalence is much higher in Latin America, Africa, and other temperate climates than in the U.S.

GENETICS: Congenital infection:

- Incidence and severity vary with the trimester of gestation during which the mother acquired infection.
  1. 10% to 25% (first trimester)
  2. 30% to 54% (second trimester)
  3. 60% to 65% (third trimester)
- Congenital infection occurring in the first trimester is the most severe.
- 89% to 100% of infections in the third trimester are asymptomatic.
- Risk to the fetus is not correlated with symptoms in the mother.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acquired (immunocompetent host): Usually subclinical, though may develop adenopathy, fatigue, and other constitutional symptoms that, while generally mild, can take weeks to resolve.
- Acquired (in patients with AIDS especially with CD4 count <100, hematopoietic stem cell transplant recipients): Most common presentation is encephalitis with headache, confusion, and fever. May have motor weakness or other focal neurologic abnormalities and seizures. Can also present as pneumonitis, chorioretinitis, or other end-organ involvement.
- Acquired (immunocompromised patients):
  1. Encephalitis
  2. Myocarditis (especially in heart transplant patients)
  3. Pneumonitis
- Ocular infection in the immunocompetent host: If not congenital, then presents in second or third decade of life as a focal necrotizing retinitis with photophobia, blurred vision, pain, and potentially loss of central vision if the macula is involved.
- Congenital: Results from acute infection acquired by the mother within 6 to 8 weeks before conception or during gestation and is usually asymptomatic in the mother. In the infant, symptomatic disease is estimated at 40%. Ocular disease can include chorioretinitis and blindness, while CNS manifestations can include intracranial calcifications resulting in epilepsy, hydrocephalus, microcephaly, psychomotor or mental retardation, and encephalitis.

ETIOLOGY

- *Toxoplasma gondii:*
  1. Ubiquitous intracellular protozoan
  2. Present worldwide
  3. Cat is the definitive host (Fig. E1)
  4. Oocysts can remain viable up to a year in moist soil, despite freezing temperatures.
- Human infection:
  1. Ingestion of oocysts shed by cats in soil, litter boxes, vegetables
  2. Ingestion of inadequately cooked meat or shellfish containing tissue cysts
  3. Vertical transmission

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphadenopathy:
  1. Infectious mononucleosis
  2. Cytomegalovirus (CMV) mononucleosis
  3. Cat-scratch disease
  4. Sarcoidosis
  5. Tuberculosis
  6. Lymphoma
  7. Metastatic cancer
- Cerebral mass lesions in immunocompromised host:
  1. Lymphoma
  2. Tuberculosis
  3. Bacterial abscess
- Pneumonitis in immunocompromised host:
  1. *Pneumocystis jiroveci (carinii)* pneumonia
  2. Tuberculosis
  3. Fungal infection
- Chorioretinitis:
  1. Syphilis
  2. Tuberculosis
  3. Histoplasmosis (competent host)
  4. CMV
  5. Herpes simplex
  6. Fungal infection
  7. Tuberculosis
- Myocarditis:
  1. Organ rejection in heart transplant recipients
- Congenital infection:
  1. Rubella
  2. CMV
  3. Herpes simplex
  4. Syphilis
  5. Listeriosis
  6. Erythroblastosis fetalis
  7. Sepsis

WORKUP

- Acute infection, immunocompetent host:
  1. Complete blood count
  2. *Toxoplasma* serology (IgG, IgM) in serial blood specimens 3 weeks apart
  3. Lymph node biopsy if diagnosis uncertain
- Immunocompromised host:
  1. Central nervous system (CNS) symptoms:
     a. Cerebral CT scan or MRI if CNS symptoms present
     b. Spinal tap, if safe
     c. Brain biopsy if no response to empiric therapy
  2. Ocular symptoms:
     a. Funduscopic examination
     b. Serologic studies
     c. Rarely, vitreous tap
  3. Pulmonary symptoms:
     a. Chest x-ray examination
     b. Bronchoalveolar lavage
     c. Transbronchial or open-lung biopsy
  4. Myocarditis:
     a. Cardiac enzymes
     b. Electrocardiogram
     c. Endomyocardial biopsy for definitive diagnosis
- Toxoplasmosis in pregnancy (Fig. 2):
  1. Initial maternal screening with IgM and IgG
     a. If negative, mother at risk of acute infection and should be retested monthly
     b. If both IgG and IgM positive, obtain IgA and IgE ELISA, AC/HS test
     c. IgA and IgE ELISA, AC/HS test elevated in acute infection
     d. Ig high for 1 yr or more
     e. IgG repeated 3 to 4 weeks later to determine if titer is stable
  2. Acute maternal infection not excluded or documented:
     a. Fetal blood sampling (for culture, Ig, IgA, IgE)
     b. Amniotic fluid polymerase chain reaction (PCR)
  3. Fetal ultrasound every other week if maternal infection documented to look for ventriculomegaly, calcifications in the brain, and enlarged liver and spleen
- Congenital toxoplasmosis (Fig. 3):
  1. Placental histology
  2. Specific IgM or IgA in infant's blood

LABORATORY TESTS

- Antibody studies:
  1. More than one test necessary to establish diagnosis of acute toxoplasmosis (look for seroconversion or 4x increase)
  2. IgM antibody:
     a. Appears 5 days into infection
     b. Peaks at 2 weeks

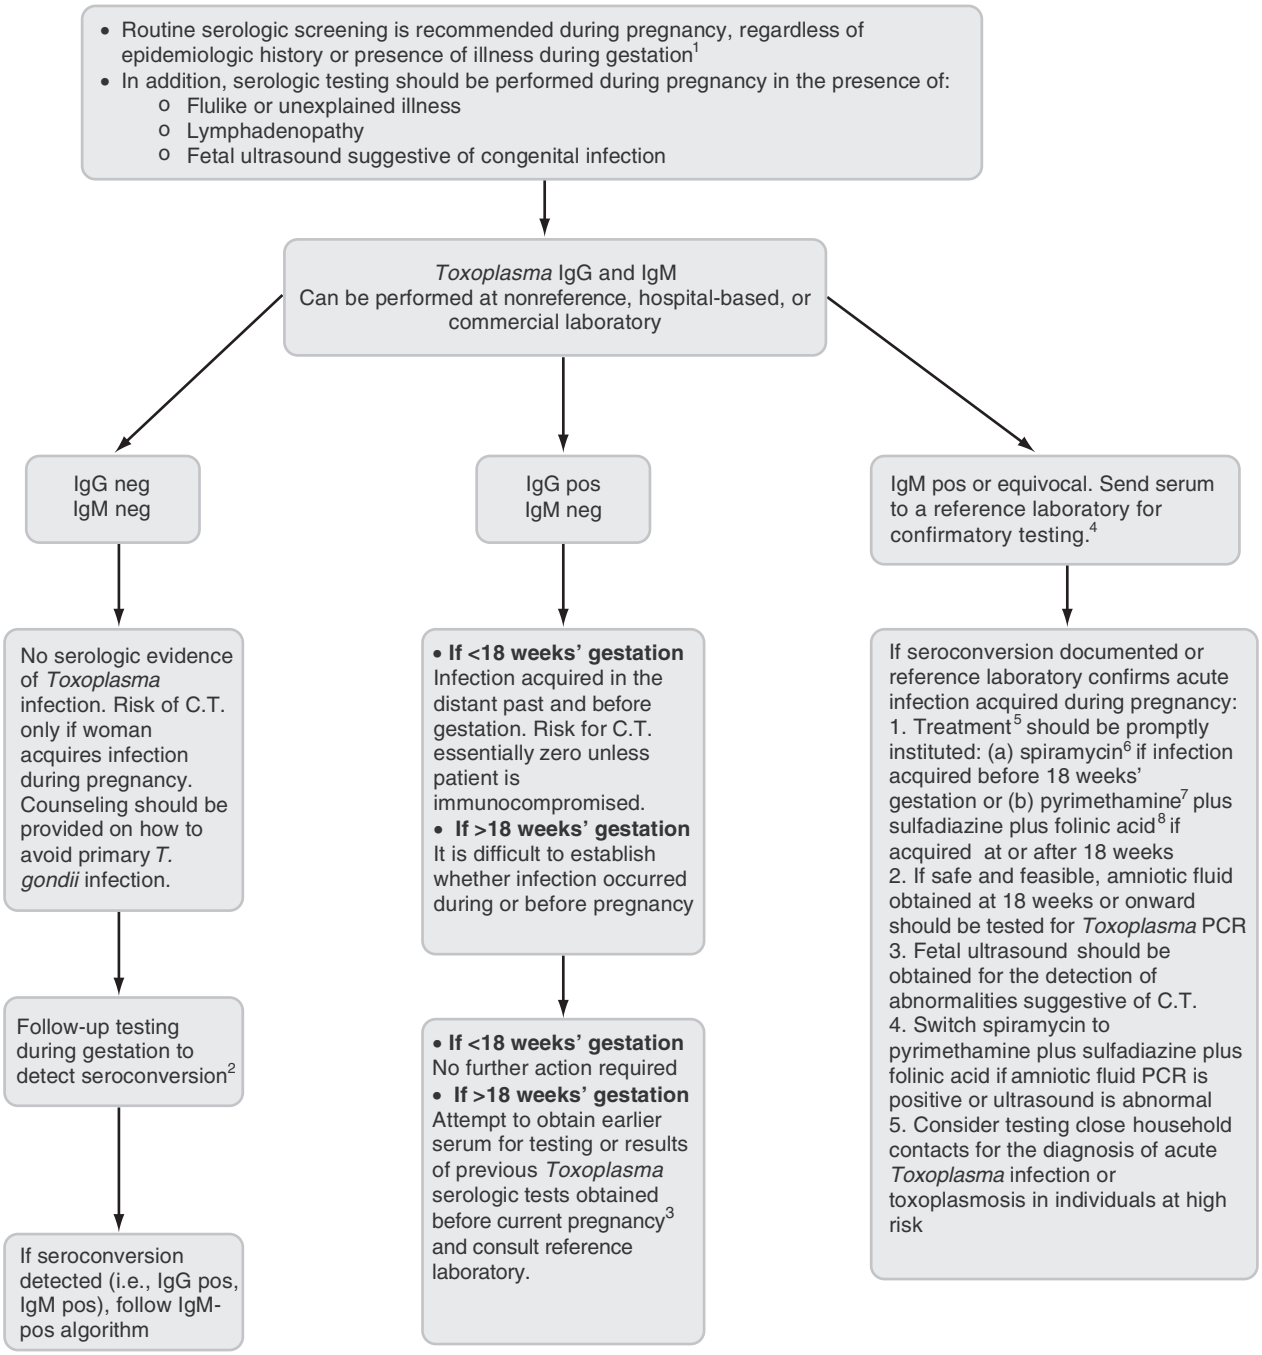

FIG. 2 Diagnostic approach and management algorithm of toxoplasmosis during pregnancy. Most of the initial serologic screening can be accomplished by nonreference or commercial laboratories. Only positive immunoglobulin M results should be considered for additional testing and consultation with medical experts at a reference laboratory. *CT,* Congenital toxoplasmosis; *IgG,* immunoglobulin G; *IgM,* immunoglobulin M; *neg,* negative test result; *pos,* positive test result. [1]Up to 50% of women who acquire *Toxoplasma* infection during gestation do not have a known risk factor for acute infection or an illness suggestive of toxoplasmosis. Thus to identify all women at risk, serologic screening should be performed in all pregnant women, along with other routine screening tests. [2]In a recent study from Lyon, France, monthly screening of seronegative pregnant women was reported to significantly decrease the risk of vertical transmission and of clinical signs at 3 years of age. Consider consultation with a physician expert in management of toxoplasmosis during pregnancy (e.g., in the U.S., Palo Alto Medical Foundation–*Toxoplasma* Serology Laboratory [PAMF-TSL], www.pamf.org/serology/; 650-853-4828; e-mail, toxolab@pamf.org; or U.S. [Chicago] National Collaborative Treatment Trial Study [NCCTS]; 773-834-4152). [4]Consider sending serum sample to a reference laboratory (e.g., PAMF-TSL). [5]Treatment regimens vary by country. The pyrimethamine-sulfadiazine-folinic acid regimen should not be offered to any pregnant woman before 12 weeks of gestation because of potential teratogenicity. In some centers in Europe, this regimen is offered at 14 weeks of gestation or later; in the U.S., it is recommended at 18 weeks or later. [6]Spiramycin is not commercially available in the U.S. It can be obtained at no cost and after consultation (with PAMF-TSL or the NCCTS through the U.S. Food and Drug Administration). [7]When using pyrimethamine, folic acid should be discontinued from the prenatal multivitamins. Folic acid can potentially counteract the antiparasitic effect of the drug. [8]Folic acid should not be erroneously used instead of folinic acid. (From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.)

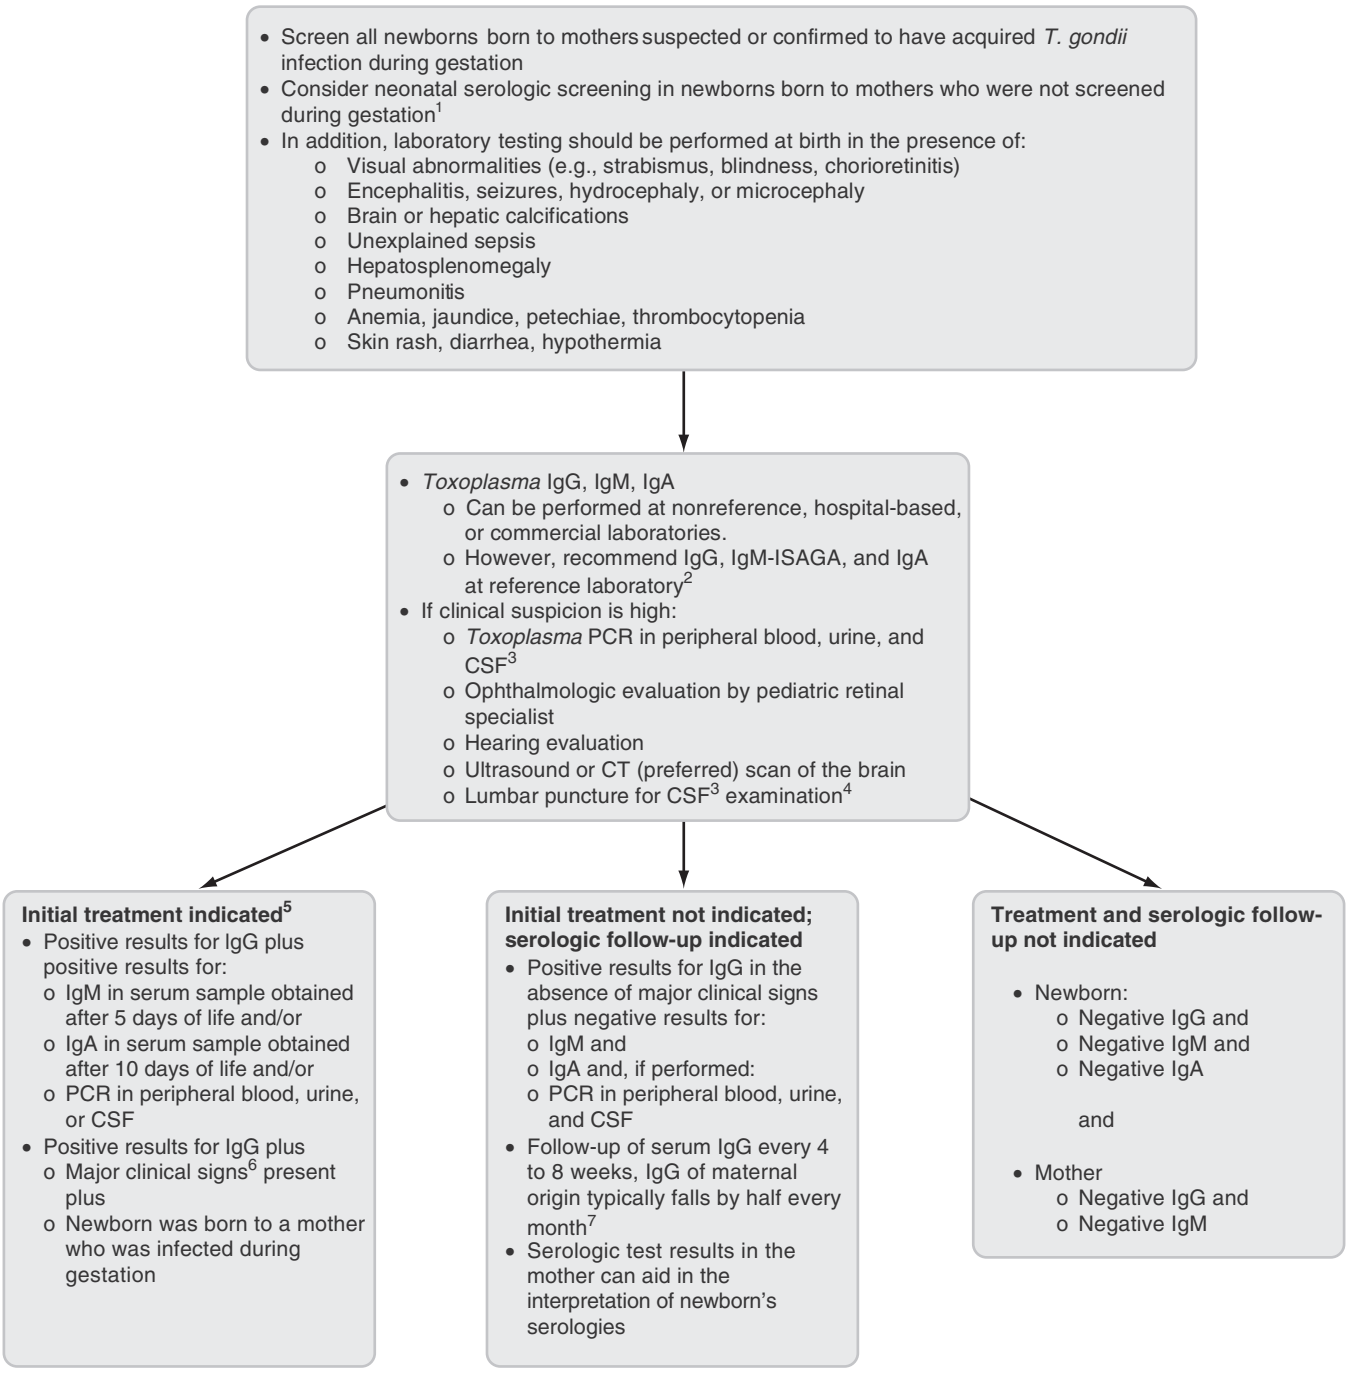

FIG. 3 Diagnostic approach and management algorithm of the newborn whose mother has been suspected or confirmed to have acquired toxoplasmosis during gestation. *CSF,* Cerebrospinal fluid; *CT,* computed tomography; *IgG, IgM,* and *IgA,* immunoglobulins G, M, and A, respectively; *ISAGA,* immunosorbent agglutination assay; *PCR,* polymerase chain reaction. [1]Consider consultation with a physician expert in management of toxoplasmosis during pregnancy (e.g., in the U.S., Palo Alto Medical Foundation–*Toxoplasma* Serology Laboratory [PAMF-TSL], www.pamf.org/serology/; 650-853-4828; e-mail, toxolab@pamf.org; or U.S. [Chicago] National Collaborative Treatment Trial Study, 773-834-4152). [2]Consider sending serum sample to a reference laboratory (e.g., PAMF-TSL). [3]If lumbar puncture is clinically indicated, deemed safe, and feasible. [4]In an attempt to confirm the diagnosis of congenital toxoplasmosis, CSF should be sent for cell count and differential (congenital toxoplasmosis is one of the few causes of eosinophilic meningitis), protein (congenital toxoplasmosis is one of the few causes of extreme elevation of CSF protein), glucose, and *T. gondii* PCR. [5]The recommended regimen is pyrimethamine plus sulfadiazine plus folinic acid (see text). [6]Major clinical signs are referred here: chorioretinitis, brain calcifications, and hydrocephalus. [7]Maternally transferred IgG antibodies usually decline and disappear within 6 to 12 months of life. (From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.)

TABLE 1 Guidelines for Interpretation of Serologic Tests for Toxoplasmosis

IgG	IgM	IgG Avidity	Interpretation
Positive	Negative	—	Remote infection, immune. IgG avidity testing is best used when both IgG and IgM are positive and timing of infection is crucial, as in pregnancy (see below). False-negative IgM results occur in approximately 25% of cases when evaluating infection in the newborn. If infection is suspected in this setting, further testing (dye test, IgM EIA, IgA EIA, IgE EIA/ISAGA, PCRs, ideally with paired maternal serology tests—see text) is necessary in a reference laboratory (*Toxoplasma* Serology Laboratory, PAMF Research Institute, 795 El Camino Real, Ames Building Palo Alto, CA, 94301; 650-853-4828).
Positive	Positive or equivocal	High	Infection within the past 18 mo but likely >12 wk ago. If pregnant and beyond first trimester, consider sending specimen to reference laboratory for dye test, repeat IgG avidity and IgM EIA, IgA EIA, IgE EIA/ISAGA, and AC/HS testing (see above).
Positive	Positive or equivocal	Low	Infection within the past 12 wk. Consider sending specimen to a reference laboratory (see above) to time infection more accurately (dye test, repeat IgG avidity and IgM EIA, IgA EIA, IgE EIA/ISAGA, and AC/HS) in the setting of pregnancy.
Equivocal	Negative	—	Indeterminate. Test a new specimen or consider a different assay (IFA or ELISA).
Equivocal	Equivocal	—	Indeterminate. Test a new specimen or consider a different assay (IFA or ELISA).
Equivocal	Positive	—	Acute infection or false-positive IgM result. Test a second specimen; if IgG becomes positive or remains equivocal, consider sending specimen to a reference laboratory to time infection more accurately (dye test, IgG avidity, IgM EIA, IgA EIA, IgE EIA/ISAGA, AC/HS—see text) in the setting of pregnancy.
Negative	Negative	—	No evidence of *Toxoplasma* infection; not immune.
Negative	Equivocal	—	Either false-positive IgM result or possible recent infection. Obtain a new specimen and retest. If infection is recent, IgM and IgG should become positive, with low IgG avidity. If repeated testing is still IgG negative and IgM equivocal, patient is likely uninfected. Consider IgM ISAGA.
Negative	Positive	—	Acute infection or false-positive IgM result. Repeat testing on new specimen. If the result is the same, it is likely a false-positive IgM result. Consider IgM ISAGA.

AC/HS, Differential agglutination test; *EIA,* enzyme immunoassay; *ELISA,* enzyme-linked immunosorbent assay; *IFA,* immunofluorescence assay; *Ig,* immunoglobulin; *ISAGA,* immunosorbent agglutination assay; *PCR,* polymerase chain reaction.
From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

   c. Falls to low level or disappears within 2 months
   d. May persist at low levels for 1 year or more
3. Antibody not measurable:
   a. Ocular toxoplasmosis
   b. Reactivation
   c. Immunocompromised hosts
4. IgG antibody:
   a. Appears 1 to 2 weeks after infection
   b. Peaks at 6 to 8 weeks
   c. Gradually declines over months to years
5. Guidelines for interpretation of serologic tests for toxoplasmosis are summarized in Table 1.

IMAGING STUDIES

- Chest x-ray if pulmonary involvement suspected
- Cerebral CT scan (Fig. E4) or MRI if encephalitis suspected

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Selected cases of ocular infection:
  1. Photocoagulation
  2. Vitrectomy
  3. Lentectomy
- Selected cases of congenital cerebral infection:
  1. Ventricular shunting

ACUTE GENERAL Rx

- Acute infection, immunocompetent, nonpregnant host:
  1. Usually requires no treatment, unless severe and persistent symptoms or vital organ damage
- Acute infection, immunocompromised host, non-AIDS:
  1. Treat even if asymptomatic
  2. Duration:
     a. Until 4 to 6 weeks after resolution of all signs and symptoms
     b. Usually 6 months or longer
- Reactivated infection, immunocompromised host, non-AIDS:
  1. Treat if symptomatic
- Acute or reactivated infection, AIDS:
  1. Treat in all cases
  2. Induction course:
     a. 3 to 6 weeks
     b. Maintenance therapy continued for life; consider discontinuation of suppressive therapy if the patient has a good response to antiretroviral therapy and if the CD4 count remains >200 cells/mm^3 for more than 3 months
  3. Empiric therapy:
     a. AIDS with positive IgG
     b. Multiple ring-enhancing lesions on cerebral CT scan or MRI
     c. Response seen by day 7 in 71% and day 14 in 91%
- Ocular infection:
  1. Treat in all cases
  2. Therapy continued for 1 month or longer if needed
  3. Response seen in 70% within 10 days
  4. Retreat as needed
  5. Steroids may be indicated in patients with signs or symptoms of increased intracranial pressure
  6. Surgical treatment in selected cases
- Treatment regimens (Table 2):
  1. Pyrimethamine 200 mg loading dose once PO, then 50 mg (<60 kg) to 75 mg (>60 kg) q day; *plus*
  2. Leucovorin 10 to 20 mg PO qid; *plus*
  3. Sulfadiazine 1 (<60 kg) to 1.5 g (>60 kg) PO q6h

  Other treatment options (if sulfa hypersensitivity or allergy is present): Pyrimethamine 50 to 75 mg/day PO with leucovorin 10 to 20 mg/day PO and either (1) clindamycin 600 mg q6h PO or IV (up to 1200 mg IV) q6h, or (2) clarithromycin 1 g PO bid, or (3) dapsone 100 mg/day PO, or (4) atovaquone 750 mg PO q6h.
- Acute infection in pregnancy:
  1. Treat immediately
  2. Risk of fetal infection reduced by 60% with treatment
     a. Seroconversion in the first trimester
        (1) Spiramycin 1 g every 8 hours
     b. Seroconversion beyond the first trimester or positive amniotic fluid PCR/ultrasound findings consistent with congenital toxoplasmosis:
        (1) Sulfadiazine 75 mg/kg/day in two divided doses ×2 days, then 50 mg/kg twice daily, *plus*
        (2) Pyrimethamine 50 mg bid ×2 days, then 50 mg PO daily, *plus*
        (3) Leucovorin 10 to 20 mg PO daily
- Postnatal treatment of congenital infection:
  1. Sulfadiazine 50 mg/kg PO bid, *plus*
  2. Pyrimethamine 2 mg/kg PO for 2 days, then 1 mg/kg PO daily for the first 2 to 6 months, then three times weekly, *plus*
  3. Leucovorin 5 to 20 mg PO three times weekly
  4. Minimum duration of treatment: 12 months

TABLE 2 Treatment of Toxoplasmosis

Disease	Medication	Dosage	Length of Therapy
Acute acquired—generally not treated unless severe or persistent symptoms, vital organ damage, or host immunosuppression[a]	Pyrimethamine *plus*	2 mg/kg/day for 2 days, then 1 mg/kg/day	4-6 wk or 2 wk after symptoms resolve for normal host; 4–6 wk beyond resolution for immunosuppressed hosts. In AIDS patients, treat until $CD4^+$ count >200
	Sulfadiazine *plus*	75-100 mg/kg/day divided twice daily (maximum 4 g/day); consider the lower dose in children >20 kg (see text)	
	Folinic acid	5-20 mg 3 times weekly; use higher doses if marrow suppression	
Ocular, older child	Pyrimethamine *plus*	2 mg/kg/day for 2 days, then 1 mg/kg/day (maximum 50 mg/day)	4-6 wk or 2 wk after symptoms resolve
	Sulfadiazine *plus*	75-100 mg/kg/day divided twice daily (maximum 4 g/day); consider the lower dose in children >20 kg (see text)	Prednisone should be continued until resolution of sight-threatening active chorioretinitis
	Folinic acid *plus*	5-20 mg 3 times weekly	
	Prednisone	1 mg/kg/day divided twice daily	
Congenital	Pyrimethamine *plus*	2 mg/kg per day for 2 days, then 1 mg/kg/day for 6 mo, then 3 times weekly (M-W-F) for 6 mo	1 yr
	Sulfadiazine *plus*	100 mg/kg per day divided twice daily	
	Folinic acid *plus*	5-10 mg 3 times weekly	
	Prednisone	1 mg/kg/day divided twice daily	Until resolution of elevated CSF protein level or sight-threatening active chorioretinitis
Pregnant women—acute infection first 21 wk of gestation	Spiramycin	3 g/day divided twice daily without food	Until fetal infection documented or excluded at 21 wk of gestation; if fetus infected, change to pyrimethamine plus sulfadiazine plus folinic acid until delivery
Pregnant women—fetal infection confirmed (amniotic fluid PCR positive)	Pyrimethamine *plus*	100 mg/day divided twice daily for 2 days, then 50 mg/day	Until delivery
	Sulfadiazine *plus*	3 g/day divided twice daily	
	Folinic acid	5-20 mg/day	

AIDS, Acquired immunodeficiency syndrome; *CSF,* cerebrospinal fluid; *PCR,* polymerase chain reaction.
[a]For more detailed recommendations for patients with human immunodeficiency virus infection/AIDS, see http://aidsinfo.nih.gov/guidelines.
From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

CHRONIC Rx

Maintenance therapy in AIDS patients because of the high risk (80%) of relapse:
- Pyrimethamine 25 mg PO qid
- Sulfadiazine 500 mg PO qid
- Leucovorin 10 to 20 mg PO qid

DISPOSITION

- Prognosis:
  1. Excellent in the immunocompetent host
  2. Good in ocular infection (although relapses are common)
- Treatment of acute infection in pregnancy:
  1. Reduces incidence and severity of congenital toxoplasmosis
- Treatment of congenital infection:
  1. Improvement in intellectual function
  2. Regression of retinal lesions
- AIDS:
  1. 70% to 95% response to therapy

REFERRAL

- To infectious disease expert:
  1. Immunocompromised hosts
  2. Pregnant women
  3. Difficulty in making a diagnosis or deciding on treatment
- To pediatric infectious disease expert:
  1. Congenital infection
- To obstetrician:
  1. Pregnant seronegative mother
  2. Acute seroconversion
- To ophthalmologist:
  1. Congenital infection
  2. Any case of ocular infection

PEARLS & CONSIDERATIONS

COMMENTS

- Prevention of toxoplasmosis is most important in seronegative pregnant women and immunocompromised hosts.
- Patient instructions:
  1. Cook meat to 66° C (150.8° F).
  2. Cook eggs.
  3. Do not drink unpasteurized milk.
  4. Wash hands thoroughly after handling raw meat.
  5. Wash kitchen surfaces that come in contact with raw meat.
  6. Wash fruits and vegetables.
  7. Avoid contact with materials potentially contaminated with cat feces.

BASIC INFORMATION

DEFINITION

Bacterial tracheitis is an acute infectious disease affecting the trachea and large conducting airways. Tracheal inflammation may be caused by a large number of inhaled stimuli, but bacterial infection is a life-threatening illness associated with purulent secretions and subglottic edema.

SYNONYMS

Bacterial tracheobronchitis
Pseudomembranous croup
Membranous laryngotracheobronchitis

ICD-10CM CODES

J04.1 Acute tracheitis
J04.10 Acute tracheitis without obstruction
J04.11 Acute tracheitis with obstruction

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Uncommon
- May be the most common cause of acute upper airway obstruction requiring admission to pediatric ICUs

PEAK INCIDENCE: Three fourths of cases reported in winter

PREDOMINANT SEX: Boys > girls in one series

PREDOMINANT AGE:

- 1 mo to 8 yr
- Almost all <13 yr (most <3 yr)

GENETICS:

- Down syndrome is a possible predisposing factor.
- Congenital infection: Some cases have been found in those with anatomic abnormalities of the upper airways.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Croupy or "brassy" cough
- Inspiratory stridor (frequent)
- Wheezing (unusual)
- Fever (often >102° F [38.9° C])
- Thick, purulent secretions expectorated:
  1. Minority of patients expectorate "ricelike" pellets.
  2. Most patients are unable to mobilize secretions.
     a. Become inspissated
     b. Form pseudomembranes

ETIOLOGY

- *Staphylococcus aureus* (including methicillin-resistant *S. aureus* [MRSA])
- *Haemophilus influenzae*
- Beta-hemolytic streptococcal infection
- Secondary to viral infections of the respiratory tract:
  1. Primary influenza
  2. Respiratory syncytial virus (RSV)
  3. Parainfluenza
- Many cases follow measles:
  1. Especially when accompanied by chest radiographic infiltrates
  2. Sometimes fatal outcome
  3. Associated with prolonged endotracheal intubation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Viral croup
- Epiglottitis
- Diphtheria
- Necrotizing herpes simplex infection in the elderly
- Cytomegalovirus in immunocompromised patients
- Invasive aspergillosis in immunocompromised patients

WORKUP

DIRECT LARYNGOSCOPY:

- Typical secretions:
  1. May form pseudomembranes
  2. Airway obstruction
- Normal epiglottis rules out epiglottitis
- Possible subglottic edema

LABORATORY TESTS

- White blood count is sometimes elevated.
- On differential, left shift is almost universal.
- Gram stain and culture of tracheal secretions confirm diagnosis.
- Blood cultures are positive in a minority.
- Viral respiratory panels using PCR technology are available on throat and nasopharyngeal swabs and can detect multiple viruses including influenza, parainfluenza and RSV, and thus can differentiate between bacterial and viral infections.

IMAGING STUDIES

- Lateral x-ray examination of neck:
  1. Normal epiglottis
  2. Vague density or a "dripping candle" appearance of tracheal mucosa:
     a. Secretions
     b. Pseudomembranes
- Chest radiograms:
  1. Not diagnostic
  2. Should not be performed on patients in acute respiratory distress, because severe or fatal upper airway obstruction can develop suddenly
- Pneumonic infiltrates frequent
- Atelectasis: Unusual but can lead to lobar collapse

TREATMENT

NONPHARMACOLOGIC THERAPY

- Aggressive maintenance of a patent airway:
  1. Laryngoscopy or bronchoscopy used diagnostically and therapeutically to strip away pseudomembranes
  2. Voluminous and tenacious secretions suctioned from the underlying friable mucosa:
     a. May extend from between the vocal cords to the main carina
     b. Larger channels of rigid instruments for more effective suctioning
- Prevention of complete large airway obstruction:
  1. Nasotracheal intubation
  2. Humidification of inspired gas
  3. Frequent saline instillation and suctioning
  4. Intubation with general anesthesia, performed in the operating room, is preferred by some
- Ventilatory support necessary with initial management in ICU

ACUTE GENERAL Rx

- Antibiotic therapy: Start immediately, generally continued for 1 to 2 wk
- Initial therapy directed against *H. influenzae* and *S. aureus* (e.g., ceftriaxone and vancomycin (if MRSA suspected)
- Oral therapy is usually sufficient after 5 or 6 days of IV administration

DISPOSITION

- Most patients are extubated in 5 to 6 days after initiating antibiotic therapy.
- Anoxic encephalopathy is reported in 7% of survivors.

REFERRAL

Suspected diagnosis

PEARLS & CONSIDERATIONS

COMMENTS

- Infants are at increased risk of airway obstruction because of the small airway dimension.
- Presence of pneumonia and a staphylococcal cause are thought to worsen prognosis.
- Reported complications: Toxic shock syndrome, persistent postextubation stridor, pneumothorax, and volutrauma

BASIC INFORMATION

DEFINITION

Hemolytic transfusion reactions may be acute (occurring during or immediately after the transfusion) or delayed (occurring more than 24 hours after the transfusion). Acute hemolytic transfusion reaction (AHTR) is in vivo hemolysis most commonly caused by an alloantibody in a recipient's plasma to a cognate antigen on the donor red cells. The most commonly involved alloantibodies are to ABO antigens, but alloantibodies to minor blood group antigens have also been implicated. Typically the alloantibodies are of the IgM class, but complement fixing IgGs may also cause such a reaction. The clinical features vary, but usually there are high fever, chills, nausea, and backache. Red or brown urine may be passed due to hemoglobinuria. The plasma may show hemoglobinemia, and the direct Coombs test can be either positive or negative. Delayed hemolytic reactions are usually caused by an anamnestic alloantibody response upon re-exposure to cognate erythrocyte antigen. They are typically IgG and usually noncomplement fixing. They occur 1 to 10 days after transfusion. In delayed transfusion reactions, hemoglobinemia is unusual, and the only clinical manifestations may be fever, the serological finding of a newly positive indirect antiglobulin (indirect Coombs test), and/or the presence of a positive direct Coombs test. Delayed reactions can be clinically silent (called delayed serological hemolytic reactions) or manifest with fever, chills, nausea, vomiting, unexplained anemia, or jaundice. There is no specific treatment other than supportive care.

SYNONYMS

AHTR
DSTR
DHTR
Acute hemolytic transfusion reaction

ICD-10CM CODES

T80.3 ABO incompatibility reaction
T80.4 Rh incompatibility reaction
T80.8 Other complications following infusion, transfusion, and therapeutic injection
T80.9 Unspecified complication following infusion, transfusion and therapeutic injection

EPIDEMIOLOGY & DEMOGRAPHICS

- Approximately 1% of transfused products result in serious adverse reactions; hemolytic transfusion reactions account for up to 5% of these serious adverse reactions.
- Acute intravascular hemolysis occurs in one to five per 50,000 transfusions.
- Delayed reactions occur about 1:1500 red cell transfusions.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fever, chills, nausea, tachycardia, chest pain, dyspnea, dizziness, bronchospasm.
- Lower back pain due to ischemic muscle pain or vasospasm hypotension.
- Severe reactions may occur in surgical patients under anesthesia who are unable to give any warning signs.
- Patients with delayed hemolytic transfusion reactions typically do not present as a clinical emergency. In most cases, presentation is with a low-grade fever from the generation of IL-1 or other proinflammatory cytokines. Hemoglobinuria and hemoglobinemia are rarely present. Unexplained anemia and jaundice are other possible presentations.
- Tables 1 and 2 summarize signs and symptoms of acute adverse reactions to blood transfusion. In the differential diagnosis of hemolysis.

ETIOLOGY

Most fatal hemolytic reactions are caused by clerical errors and mislabeled specimens.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Septic reaction
- Transfusion-related acute lung injury

MANAGEMENT

The transfusion must be stopped immediately. The blood bank must be notified, and the donor transfusion bag must be returned to the blood bank along with a freshly drawn posttransfusion specimen. Table 3 summarizes immediate investigations in the case of an acute transfusion reaction.

LABORATORY TESTS

- The direct antiglobulin test (DAT) is usually positive in a delayed reaction, and preparation of an eluate will help identify the offending antibody.
- In some delayed reactions, the only finding is a positive indirect Coombs test, and the implicated alloantibody can be identified in an antibody panel.
- In acute reactions, the urine may show hemoglobinuria (wine-colored urine) and the plasma hemoglobinemia (pink plasma).
- Labs (Table 4): Decreased hematocrit and serum haptoglobin (haptoglobin low to 0 mg/dl). Elevated LDH, indirect bilirubin and creatinine, if acute.
- In acute cases, monitor coagulation status (PT, aPTT, fibrinogen) for disseminated intravascular coagulation.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Stop transfusion immediately. Test anticoagulated blood from the recipient for the presence of free hemoglobin in the plasma.
- Monitor vital signs closely and maintain IV access with a suitable crystalloid or colloid solution.
- Maintain an adequate airway.

ACUTE GENERAL Rx

- Treatment is supportive and consists of fluid resuscitation, vasopressor support, and mannitol.
- Vigorous IV hydration (0.9% NaCl or some other suitable crystalloid solution) to maintain urine flow at >100 ml/hr until hypotension is corrected and hemoglobinuria clears. IV furosemide may be necessary to maintain adequate renal flow.
- The addition of mannitol may prevent renal damage (controversial). Mannitol, if chosen,

TABLE 1 Signs and Symptoms of Acute Adverse Reactions to Blood Transfusion

TABLE 3 Immediate Investigations in the Case of an Acute Transfusion Reaction

Check for hemolysis.
Perform visual examination of patient's plasma and urine (plasma and urine hemoglobin can be checked, but this is not essential).
Blood film may show spherocytosis.
Bilirubin and lactate dehydrogenase (LDH) levels will be raised.
Check for incompatibility.
Check the documentation and the patient's identity.
Repeat ABO group of patient on pretransfusion and posttransfusion samples and of the donor unit(s).
Screen the patient for red cell antibodies pretransfusion and posttransfusion.
Repeat crossmatch with pretransfusion and posttransfusion samples.
Direct antiglobulin test (DAT) on pretransfusion and posttransfusion samples.
Eluate from patient's red cells.
Check for disseminated intravascular coagulation.
Perform blood count and film, coagulation screen, and fibrin degradation products (or D-dimers).
Check for renal dysfunction.
Check blood urea, creatinine, and electrolytes.
Check for bacterial infection.
Take blood cultures from the patient and donor unit including immediate Gram stain.

From Bain BJ, Bates I, Laffan MA: *Dacie and Lewis practical haematology,* ed 12, Philadelphia, 2017, Elsevier.

TABLE 4 Hemolytic Transfusion Reactions: Serologic Presentation

Type	Antibody Detectable Initially	Primary Antibody Type	Degree of Complement Binding	Example
Acute intravascular	Yes	IgM	Full (C1-9)	ABO system
Acute extravascular	Yes	IgG	None/partial	Rh system
Delayed intravascular	No	IgG	Full (C1-9)	Kidd system
Delayed extravascular	No	IgG	None/partial	Duffy system

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

must be used with caution; if acute tubular necrosis occurs before mannitol infusion, pulmonary edema may occur as a result of the acute increase in intravascular volume secondary to fluid expansion.
- Monitor for the presence of disseminated intravascular coagulation. PT, aPTT, and fibrinogen levels should be closely monitored.
- If sepsis is suspected, culture as appropriate.

DISPOSITION

Mortality rate is 3% to 10% in severe transfusion reactions.

PEARLS & CONSIDERATIONS

COMMENTS

Hemolysis caused by minor antigen systems is generally less severe and may be delayed 1 to 10 days after transfusion.

Panch SR: Hemolytic transfusion reactions, *N Engl J Med* 381:150–162, 2019.

BASIC INFORMATION

DEFINITION

A clinical syndrome lasting up to 24 hours of sudden onset, severe anterograde and variable retrograde amnesia without loss of other neurologic function.

SYNONYM

TGA

ICD-10CM CODE
G45.4 Transient global amnesia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 3.4 to 10.4 per 100,000 people.
PEAK INCIDENCE: Most between ages 50 to 70 and equally common in men and women. In population older than 50 the incidence increases to 23.5 per 100,000 per year. TGA is also more common in individuals with migraine.[1]
RECURRENCE RATE: 2.9% to 23.8%

PHYSICAL FINDINGS & CLINICAL PRESENTATION[2]

- Cannot recall novel episodic information, repeatedly asking the same questions
- No impairment in consciousness or nonmemory cognitive domains, no focal neurologic deficit
- Complex procedural memory is often preserved (i.e., driving)
- Triggers include Valsalva maneuver, immersion in cold or hot, sexual intercourse, emotional stress
- Typically a single attack that is self-limited, with amnestic gap of the duration of episode
- Those with recent head injury or epilepsy diagnosis are excluded

[1] Arena JE et al: Transient global amnesia, *Mayo Clin Proc* 90(2):264-272, 2015.
[2] Arena JE et al: Long-term outcome in patients with transient global amnesia: a population-based study, *Mayo Clin Proc* 92(3):399-405, 2017.

ETIOLOGY

- Several proposed mechanisms of pathophysiology:
  1. Hypoperfusion or arterial ischemia of the hippocampi
  2. Internal jugular venous flow reversal causing venous hypertension to the medial temporal lobe
  3. Migraine phenomena with cortical spreading depression

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Posterior cerebral artery transient ischemic attack: Can be associated with confusion or memory loss. Commonly with vascular risk factors and other focal neurologic signs (homonymous hemianopsia, aphasia, hemiparesis, hemisensory loss, hemi-body pain, oculomotor nerve palsy or vertical gaze palsy).
- Transient epileptic amnesia: Epilepsy syndrome, consisting of atypical TGA or recurrent attacks of amnesia, often less than one hour and upon waking, responsive to antiepileptic medications. Associated with olfactory hallucinations or oral automatisms. Interictal EEG may be abnormal. Hippocampal atrophy on MRI may be seen.
- Dissociative fugue, or transient dissociative amnesia: Extensive retrograde amnesia, loss of personal identity may occur, unlike in TGA where such is preserved.
- Hypoglycemia: Metabolic dysfunction can cause impairment in consciousness, focal signs, or prolonged cognitive impairment unlike TGA.

WORKUP

- Largely a clinical diagnosis, workup should focus on exclusion of vascular or epileptic source of symptoms.
- Collateral history of witnessed event and exclusion of prior event.
- Cognitive examination with evaluation of registration, delayed recall, and orientation.
- Careful cranial nerve examination to exclude posterior circulation stroke.

LABORATORY TESTS

- Complete blood count with erythrocyte sedimentation rate and C-reactive protein
- Serum chemistries, including lipid profile
- Troponins and electrocardiogram

DIAGNOSTIC STUDIES

- MRI of the brain may show reversible T2 hyperintensity or diffusion restriction exclusive to the hippocampi.
- Electroencephalogram (EEG) to exclude epileptiform activity.

TREATMENT

NONPHARMACOLOGIC THERAPY

Self-limited, not requiring specific pharmacologic or nonpharmacologic treatment

ACUTE GENERAL Rx

Investigate as an emergency.

CHRONIC Rx

- Does not lead to long-term sequela of memory loss. Complete recovery of cognitive function has been reported 5 days to 6 mo after the episode.
- Low risk of subsequent ischemic cerebral stroke or seizures though possible increased risk of future dementia

DISPOSITION

Due to the benign nature of transient global amnesia, rarely is continued followup necessary.

REFERRAL

Referral to a neurologist is necessary when the diagnosis is uncertain or with atypical features of the clinical presentation.

Transient Ischemic Attack ALG PTG

BASIC INFORMATION

DEFINITION

Transient ischemic attack (TIA) is a transient episode of neurologic dysfunction caused by focal brain, spinal cord, or retinal ischemia without acute infarction on MRI. TIA symptoms typically resolve within 60 min and by definition within 24 hours. Despite complete symptom resolution, 20% to 50% of patients clinically suspected to have suffered a TIA have evidence of acute tissue infarction on MRI.

SYNONYMS

TIA
Amaurosis fugax
Ophthalmologic TIA
"Mini-stroke"
Pre-stroke

ICD-10CM CODES

G45.9	Transient cerebral ischemic attack, unspecified
G45.8	Other transient cerebral ischemic attacks and related syndromes
Z86.73	Personal history of transient ischemic attack (TIA), and cerebral infarction without residual deficits

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 70 to 101 cases per 100,000 persons annually
PEAK INCIDENCE: After age 60 yr
PREVALENCE: 200,000 to 500,000 persons in the United States. The annual risk of stroke after either a TIA or minor stroke is approximately 3% to 4%.
PREDOMINANT SEX AND RACE: Males > females; African American > Caucasian
RISK FACTORS: Same as for ischemic stroke

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- TIAs often present with transient neurologic symptoms including ipsilateral transient monocular blindness (amaurosis fugax), contralateral numbness or weakness, contralateral homonymous hemianopsia, and/or aphasia.
- Box 1 summarizes carotid artery TIAs.
- Vertebrobasilar artery TIAs are described in Box 2.

ETIOLOGY

Embolic (cardioembolism in 10% to 15%) large vessel atherothrombotic disease (20% to 25%) lacunar disease, hypoperfusion, hypercoagulable state, arteritis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Seizures, hypoglycemia, hemiplegic migraine, intracranial hemorrhage, mass lesion, vestibular disease, Bell palsy, meningitis, multiple sclerosis, subdural hematoma, brain abscess, cervical or lumbar spine disease, conversion disorder

WORKUP

Given the high risk of stroke within the first 48 hours following TIA (up to 10%), hospital admission for workup is advised. Most of the immediate risk of stroke is secondary to carotid disease.

The American Heart Association recommends that the ABCD2 score be used in the evaluation of TIA. It consists of 1 point for age ≥60 yr, 1 point for BP ≥140 mm Hg systolic or ≥90 mm Hg diastolic, clinical features (2 points for unilateral weakness, 1 point for speech impairment), duration of TIA (2 points for duration ≥60 min, 1 point for duration 10-59 min), presence of diabetes mellitus (1 point). According to the guidelines, it is reasonable to hospitalize patients with TIA if they present within 72 hours and have an ABCD2 score ≥3. There is some debate about the usefulness of this scale since it fails to account for changes seen on echocardiogram, carotid Dopplers, or ECG that may place the patient at more imminent risk of stroke (carotid stenosis, Afib, cardiac thrombus, etc.). Alternatives to this scoring system are being investigated.

LABORATORY TESTS

Complete blood count, basic metabolic panel, prothrombin time, activated partial thromboplastin time, sedimentation rate, fasting lipid panel, serum glucose and hemoglobin A_{1c} (to detect latent diabetes mellitus), and TSH.

IMAGING STUDIES

- CT scan should be obtained to exclude hemorrhage; MRI with diffusion-weighted images if immediately available to determine whether infarction occurred.
- Imaging of the vessels should be obtained via magnetic resonance angiography (MRA) head and neck, computed tomography angiography (CTA) head and neck, or carotid Doppler/transcranial Doppler (CD/TCD). If symptoms are localizable to the posterior circulation, MRA or CTA should be obtained in lieu of CD/TCD.
- Transthoracic echocardiogram should be obtained.

BOX 1 Carotid Artery Transient Ischemic Attacks

Symptoms
- Contralateral hemiparesis, hemianopsia, hemisensory loss
- Aphasia, if dominant hemisphere
- Neglect and hemi-inattention, if nondominant hemisphere
- Ipsilateral amaurosis fugax

Associated findings
- Carotid bruit
- Retinal artery emboli

Tests
- Ultrasonography (carotid Doppler studies)
- Magnetic resonance imaging angiography (MRA)
- Cerebral arteriography

Therapy
- Medical: Platelet inhibitors (e.g., aspirin)
- Risk-reduction measures (e.g., control blood pressure, glucose levels, cholesterol)
- Surgical: Carotid endarterectomy, if stenosis >70% and symptomatic
- Endovascular: Placement of stent

From Kaufman DM, Geyer HL, Milstein MJ: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.

BOX 2 Vertebrobasilar Artery Transient Ischemic Attacks

Symptoms
- Vertigo, vomiting, tinnitus
- Circumoral paresthesias or numbness
- Dysarthria, dysphasia
- Drop attacks

Associated findings
- Nystagmus
- Ataxia
- Cranial nerve abnormalities

Tests
- Ultrasonography (transcranial Doppler studies)
- Magnetic resonance imaging angiography (MRA)
- Cerebral arteriography

Therapy
- Medical: Platelet inhibitors*
- Risk-reduction measures
- Surgical: None

*See Box 1.
From Kaufman DM, Geyer HL, Milstein MJ: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.

- An echocardiogram with bubble should be obtained in all patients younger than 50 yr with TIA symptoms.
- Electrocardiogram should be obtained to exclude the presence of arrhythmias, namely atrial fibrillation.
- At least 24 hours of heart rhythm monitoring should be accomplished to screen for arrhythmia. Many stroke centers now utilize prolonged ambulatory cardiac rhythm monitoring over several weeks to months to identify paroxysmal atrial fibrillation in select patients when there is a high index of clinical suspicion.
- Paroxysmal atrial fibrillation is common in patients with TIA. A recent study found that noninvasive ambulatory ECG monitoring for 30 days significantly improved the detection of atrial fibrillation by a factor of more than five and nearly doubled the rate of anticoagulant treatment as compared with the standard practice of short-duration ECG monitoring.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Carotid endarterectomy or carotid stenting should be considered for patients found to have carotid stenosis of ≥50% as the cause for TIA. Efficacy is greatest in the two weeks immediately following a TIA or ischemic stroke. Please refer to the "Carotid Artery Stenosis" chapter for more information.
- The practice of intracranial angioplasty and stenting has largely declined following the publication of negative results from clinical trials and is only used in select patients who fail maximal medical management with aggressive platelet inhibition, strict risk factor control such as hyperlipidemia, hypertension, diabetes mellitus, weight loss, treatment of sleep apnea, and smoking cessation among others.

ACUTE GENERAL Rx

- In the absence of contraindications, patients with atrial fibrillation should be considered for anticoagulation. Choices for anticoagulants include the direct oral anticoagulants (such as dabigatran, rivaroxaban, apixaban, edoxaban, betrixaban) and/or warfarin. In patients with TIA and atrial fibrillation or a cardiac thrombus, therapeutic anticoagulation should be achieved rapidly. Those who are not candidates for a direct oral anticoagulation and who will need chronic warfarin should first be started on either intravenous heparin or therapeutic anticoagulant doses of Lovenox, along with warfarin, until target INR between 2.0 and 3.0 is achieved, at which point warfarin should be continued as monotherapy.
- Although no compelling evidence exists for the use of heparin in the acute treatment of TIAs without cardioembolic source, patients who develop recurrent symptoms within the same vascular territory that increase in duration, severity, and/or frequency (crescendo TIA/stuttering TIA) may benefit from its use pending cardiac and vascular imaging and identification of a possible source.

CHRONIC Rx

- Chronic therapy includes antiplatelet or anticoagulation therapy and modifying the four major risk factors: hypertension, dyslipidemia, diabetes mellitus, and smoking cessation.
- Antiplatelet therapy should be used to reduce the risk of recurrent TIAs or subsequent stroke. Three antiplatelet agents are commonly used in stroke prevention: aspirin, aspirin/dipyridamole, and clopidogrel. All are reasonable choices, but practitioners should consider their individual patient's comorbidities when selecting an antiplatelet agent.
- A direct oral anticoagulant of dose-adjusted warfarin (INR 2.0 to 3.0) or use of direct oral anticoagulants instead of an antiplatelet is indicated for prevention of future strokes in atrial fibrillation patients.

PEARLS & CONSIDERATIONS

- All cause mortality in 1 yr is 25% in patients diagnosed TIA.
- Dual antiplatelet therapy in acute TIA and minor stroke is being evaluated. A recent trial revealed that among patients with TIA or minor stroke who can be treated within 24 hours after the onset of symptoms, the combination of clopidogrel and aspirin is superior to aspirin alone for reducing the risk of stroke in the first 90 days but did increase the risk of hemorrhage. Most of the benefit was concentrated in the first seven to 30 days, so dual antiplatelet therapy may be reasonable in the first 30 days after TIA.
- Previous studies conducted between 1987 and 2003 estimated the risk of stroke or an acute coronary syndrome was 12% to 20% during the first 3 mo after a TIA. New data estimate the 1-yr risk to be 6.2%. Multiple infarctions on brain imaging, large-artery atherosclerosis, and an ABCD[1] score of 6 or 7 were each associated with more than a doubling of the risk of stroke.[2]

PREVENTION

- A healthy lifestyle and management of cardiovascular risk factors should be encouraged.
- Antiplatelet therapy has not been proven efficacious in primary prevention of TIA or stroke but is very beneficial in secondary prevention.

PATIENT & FAMILY EDUCATION

Patients should be counseled on the early signs of stroke symptoms and instructed to promptly seek medical attention if they develop symptoms concerning for stroke. Patients should be encouraged to pursue a healthy lifestyle to include exercise and smoking cessation. In addition, patients should take an active role in controlling blood pressure and blood glucose. Further educational materials can be found online at http://www.strokecenter.org/.

BASIC INFORMATION

DEFINITION

Demyelination in a transverse region of the spinal cord due to an inflammatory process that leads to sensory and motor changes below the lesion as well as autonomic dysfunction. The term "transverse myelitis" of late refers to any cause of inflammatory myelopathy, irrespective of severity or degree of structural or functional interruption of pathways through a transverse spinal cord section. Transverse myelitis that extends across three or more segments of the cord is referred to as longitudinally extensive transverse myelitis. The pathologic hallmark of transverse myelitis is the presence of focal collections of lymphocytes and monocytes with varying degrees of demyelination, axonal injury, and astroglial and microglial activation within the spinal cord.

SYNONYMS

Idiopathic transverse myelitis (ITM)
TM
ITM

ICD-10CM CODES

G37.3	Acute transverse myelitis in demyelinating disease of central nervous system
G04.89	Other myelitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Annual incidence ranges from 1.3 to 8 cases per million. The incidence increases to 24.6 cases per million annually if causes of acquired demyelination such as multiple sclerosis (MS) or neuromyelitis optic spectrum disorder are included.
PREVALENCE: Unknown
PREDOMINANT SEX: None, but female preponderance seen in cases associated with multiple sclerosis and neuromyelitis optica spectrum disorder.
GENETICS: No genetic predisposition has been shown.
PEAK INCIDENCE: Can occur at any age. Bimodal peak in the incidence between 10 to 19 yr and 30 to 39 yr. 20% of cases occur in children with a bimodal peak of incidence between 0 to 2 yr and 5 to 17 yr.
RISK FACTORS: Infection, vaccination

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Rapid onset of symmetric or asymmetric paraparesis or paraplegia of the lower extremities over a few days, ascending paresthesia, sensory level at the trunk, back pain, sphincter dysfunction, and positive Babinski, which can be bilateral. The arms may also be involved if the cervical cord is involved, but cervical involvement is less common than thoracic involvement. In the acute phase the weakness is flaccid, with diminished deep tendon reflexes mimicking a peripheral neuropathy such as Guillain-Barré syndrome.
- One third to one half of patients present with localizing back pain or a bandlike area of altered sensation, usually at the dermatomal level corresponding to the lesion within the cord.
- There is progression to nadir of clinical deficits between 4 hr and 21 days after symptom onset.
- Urinary incontinence or retention, GI disturbances (incontinence or constipation), and sexual dysfunction are common.
- Acute flaccid myelitis is a subtype of myelitis in which patients present with acute limb weakness and have primarily involvement of gray matter on spinal cord imaging.

ETIOLOGY

- The clinical signs are caused by an interruption in ascending and descending sensory, motor, and autonomic pathways in the transverse plane of the spinal cord, resulting in sensory-level weakness and autonomic dysfunction at and below the level of the lesion due to demyelination or inflammation of the spinal cord.
- Can be idiopathic demyelination (15% to 30%) that is a monophasic one-time event or demyelination secondary to neurologic or systemic conditions (Box 1).
- Secondary causes include postinfection, postvaccination, acute demyelinating encephalomyelitis (where transverse myelitis tends to be monophasic), and others such as multiple sclerosis, neuromyelitis optica spectrum disorder (NMOSD), connective tissue disorders such as systemic lupus, Sjögren syndrome, antiphospholipid antibody syndrome, sarcoidosis, and paraneoplastic conditions, which can be progressive or relapsing.
- Infectious causes of myelitis include HIV, syphilis, varicella zoster (associated with shingles), HTLV-1, Lyme disease, arboviruses such as West Nile virus (typically causing a poliomyelitis-type acute flaccid paralysis), or enteroviruses (typically causing acute flaccid paralysis mainly in children).
- About 50% of patients have had a recent upper respiratory infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- MS (Table 1)
- Neuromyelitis optica spectrum disorder (NMOSD)
- Metastatic disease
- Spinal cord tumors
- Herniated or slipped discs
- Spinal stenosis
- Spinal epidural abscess
- Vascular malformation

BOX 1 Central Nervous System and Systemic Autoimmune Disorders Associated with Acute Transverse Myelitis

Central Nervous System Disorders
Acute disseminated encephalomyelitis
Multiple sclerosis
Neuromyelitis optica

Systemic Autoimmune Disorders

1. Spinal dural arteriovenous fistula (most common)
2. Arteriovenous malformation of the spinal cord

- Spinal cord infarction due to either anterior spinal artery or posterior spinal artery occlusion

WORKUP

Transverse myelitis (TM) should be suspected in patients with a history of rapid (hours to days) onset of motor weakness and sensory abnormalities with bladder or bowel dysfunction that is referable to the spinal cord. The dysfunction is bilateral (not necessarily symmetric), and there is a clearly defined sensory (dermatomal) level. It is important to distinguish idiopathic TM from TM due to MS or neuromyelitis optica spectrum disorder because idiopathic TM does not relapse and does not require long-term immunomodulatory therapy. A suggested diagnostic workup for recurrent CNS demyelinating disorders and systemic autoimmune disorders associated with acute transverse myelitis is summarized in Table 2.

IMAGING STUDIES

- Gadolinium-enhanced magnetic resonance imaging (MRI) of brain and MRI of the entire spine (Fig. E1, Fig. E2). This will show demyelinating lesion on T_2 with contrast enhancement. In MS there is usually a short segment lesion (less than three vertebral segments) that is dorsally located. Longitudinally extensive transverse myelitis that spans more than three or more segments of the cord is more typical of NMOSD, postinfectious, vascular, or other inflammatory causes.
- Computed tomography (CT) of the spine with and without contrast should be obtained if MRI is unavailable, but CT does not allow for visualization of the spinal cord itself.
- CT myelogram may also be obtained if MRI unavailable to evaluate for compression.
- Chest CT with and without contrast if sarcoidosis is suspected.

LABORATORY TESTS

- Lumbar puncture looking for CSF pleocytosis, oligoclonal bands for MS, or serology and PCR looking for infection (Table 3) such as varicella zoster virus and enterovirus PCR.
- ANA, hepatitis B serology, Lyme disease serology, VDRL, SSA, SSB, anticardiolipin antibody, lupus anticoagulant, copper, ceruloplasmin, vitamin B_{12}, RPR.
- Serum NMO-IgG and myelin oligodendrocyte glycoprotein (MOG) antibodies to evaluate for neuromyelitis optica spectrum disorder.
- If a paraneoplastic etiology is suspected, then appropriate antibodies should be ordered and appropriate cancer screening undertaken.

Rx TREATMENT

Corticosteroids (IV methylprednisolone 1 g/day for 3 to 7 days) are the first-line treatment for transverse myelitis.

NONPHARMACOLOGIC THERAPY

- Physical therapy
- Respiratory and oropharyngeal support

ACUTE GENERAL Rx

- High-dose IV corticosteroid (e.g., methylprednisolone 1000 mg/day for 3 to 7 days) to stop inflammatory damage to the spinal cord.
- Rescue therapy with plasma exchange may be helpful in patients who do not respond to corticosteroids.
- Combination therapy with plasmapheresis and corticosteroids or other immunosuppressive agents (e.g., rituximab or cyclophosphamide) may also be effective.
- Analgesia for pain.

CHRONIC Rx

- Baclofen or tizanidine for muscle spasms
- Gabapentin or pregabalin for neuropathic pain
- Low-molecular-weight heparin for DVT prophylaxis in patients with immobility
- Need for chronic immunosuppression will depend on underlying etiology

DISPOSITION

- One third of patients with transverse myelitis will have complete recovery, one third will have fair recovery, and one third have permanent disability and do not recover. Recurrence or relapse is possible, especially if the patient has MS, NMOSD, or sarcoidosis.
- Patients who need further care, including those with urinary retention, may need home nursing assistance. Some patients may benefit from rehabilitation, either inpatient or outpatient.

REFERRAL

- Referral to a neurologist to evaluate need for long-term therapy.
- Referral for physical and occupational therapy.
- Consider psychiatric consultation (high incidence of long-term mood and anxiety disorders).

Traumatic Brain Injury (TBI)

BASIC INFORMATION

DEFINITION

- Impact to the head resulting in varying levels of cellular and macroscopic changes, detected with clinical examination supplemented by imaging studies.
- Mild traumatic brain injury (TBI) is defined as loss of consciousness <30 minutes, a Glasgow Coma Scale (GCS) of 13 to 15, and normal imaging.
- Moderate TBI is defined as loss of consciousness for 30 minutes to 24 hours with even longer alteration in consciousness, a GCS of 9 to 12, and may or may not have abnormal imaging.
- Severe TBI is defined as >24 hours of loss of consciousness with a GCS of 3 to 8 and prolonged posttraumatic amnesia with normal or abnormal imaging.

SYNONYMS

TBI
Head injury
Concussion
Intracranial contusion

ICD-10CM CODES

S06.9 X0A	Intracranial injury
S06.1X7A	Traumatic cerebral edema with loss of consciousness of any duration with death due to brain injury prior to regaining consciousness, initial encounter
S06.2X9A	Diffuse traumatic brain injury with loss of consciousness of unspecified duration, initial encounter
S06.300A	Unspecified focal traumatic brain injury without loss of consciousness, initial encounter
S06.305A	Unspecified focal traumatic brain injury with loss of consciousness greater than 24 hours with return to pre-existing conscious level, initial encounter
S06.309A	Unspecified focal traumatic brain injury with loss of consciousness of unspecified duration, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

Traumatic brain injury (TBI) is a worldwide leading cause of mortality in young individuals. Urbanization and increasing use of motor vehicles has led to an overall increase in TBI, especially in high-income and developing countries.
INCIDENCE: Globally, more than 10 million people suffer TBI resulting in mortality or requiring hospitalization each yr. By 2020, it is projected that TBI will surpass many diseases as the major cause of death and disability worldwide. TBI likely accounts for 9% of global mortality and is a threat to health in every country in the world. The financial burden of TBI has been estimated to be greater than $80 billion per yr in the United States alone. According to estimates from the CDC, about 2.87 million emergency department visits, including deaths and hospitalizations, were associated with TBI in 2014.
PREVALENCE: The prevalence of TBI in the United States has been estimated at approximately 5.3 million. In the European Union with 330 million inhabitants, approximately 7,775,000 new TBI cases occur each yr. According to the CDC, combined rates of TBI-related hospitalizations, emergency department visits, and deaths have risen from 521/100,000 in 2000 to 823.7/100,000 in 2010.
PEAK INCIDENCE: Approximate incidence in the US per CDC data is 103/100,000 population. In the European Union, this is estimated to be at 235/100,000.
PREDOMINANT SEX AND AGE: TBI occurs more frequently in young adults, particularly males 15 to 25 yr of age, and has a high cost to society because of life years lost. Hospitalizations and deaths are the highest in older adults >75 yr of age.
GENETICS: TBI and Apo E ε4 synergistically are also associated with a tenfold increased risk for Alzheimer disease as well as larger intracerebral hematomas and greater ischemia after TBI.
RISK FACTORS: N/A.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

TBI patients can present with a spectrum of clinical symptoms including nausea, vomiting, headache, seizures, altered mental status, and/or coma. Stigmata of trauma, including bruises, scalp lacerations, and periorbital or mastoid ecchymosis suggesting skull base fractures, are telltale signs of possible underlying traumatic brain injury. Box 1 describes risk stratification in patients with minor head trauma. The spectrum of TBI is most commonly assessed using the GCS, which ranges from 3 to 15 and utilizes eye, motor, and verbal exams (Table 1).

ETIOLOGY

Mechanical falls (35%), motor vehicle accidents (17%), and assaults resulting in direct or indirect trauma to the head are the most common etiologies. The most deaths occur from motor vehicle accidents.

An estimated 283,000 children seek care in U.S. emergency departments each yr for a sport- or recreation-related TBI. TBIs sustained in contact sports account for approximately 45% of these visits. Football, bicycling, basketball, playground activities, and soccer account for the highest number of emergency department visits.[1]

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis of TBI is quite limited; however, there are several considerations and diagnoses considered as a possibility within the realm of TBI. These are enumerated in the imaging section.

WORKUP

TBI workup is always a part of the advanced trauma life support (ATLS) protocol. Primary and secondary survey followed by imaging studies constitutes the standardized approach to TBI. Focused TBI workup includes:

- History: Including timing of injury, duration of loss of consciousness if applicable, seizures (if any), comorbidities, use of anticoagulants and antiplatelet agents (requires reversal in the event of intracranial blood on imaging).
- Neurological examination: Glasgow Coma Scale, cranial nerves, motor/sensory exam. Assess for scalp lacerations, specifically overlying a skull fracture as well as CSF otorrhea or rhinorrhea.

BOX 1 Risk Stratification in Patients with Minor Head Trauma

High Risk
- Focal neurologic findings
- Asymmetrical pupils
- Skull fracture on clinical examination
- Multiple trauma
- Serious, painful, distracting injuries
- External signs of trauma above the clavicles
- Initial Glasgow Coma Scale score of 14 or 15
- Loss of consciousness
- Posttraumatic confusion or amnesia
- Progressively worsening headache
- Vomiting
- Posttraumatic seizure
- History of bleeding disorder or anticoagulation
- Recent ingestion of intoxicants
- Unreliable or unknown history of injury
- Previous neurologic diagnosis
- Previous epilepsy
- Suspected child abuse
- Age above 60 yr or below 2 yr

Medium Risk
- Initial Glasgow Coma Scale score of 15
- Brief loss of consciousness
- Posttraumatic amnesia
- Vomiting
- Headache
- Intoxication

Low Risk
- Currently asymptomatic
- No other injuries
- No focality on examination
- Normal pupils
- No change in consciousness
- Intact orientation and memory
- Initial Glasgow Coma Scale score of 15
- Accurate history
- Trivial mechanism
- Injury less than 24 hours ago
- No or mild headache
- No vomiting
- No preexisting high-risk factors

[1]Sarmiento K et al: Emergency Department Visits for Sports- and Recreation-Related Traumatic Brain Injuries Among Children—United States, 2010–2016, *MMWR* 68;241, 2019.

TABLE 1 Glasgow Coma Scale (GCS)

Adult		Infant
Eye Opening	**E**	**Eye Opening**
Spontaneous	4	Spontaneous
To speech	3	To speech
To pain	2	To pain
No response	1	No response
Best Motor Response	**M**	**Best Motor Response**
Obeys verbal command	6	Normal movements
Localizes to pain	5	Localizes to pain
Withdraws to pain	4	Withdraws to pain
Flexion (decorticate)	3	Flexion (decorticate)
Extension (decerebrate)	2	Extension (decerebrate)
No response	1	No response
Best Verbal Response	**E**	**Best Verbal Response**
Oriented speech	5	Coos, babbles
Disoriented speech	4	Cries but consolable
Inappropriate words	3	Persistently irritable
Incomprehensible sounds	2	Grunts to pain/restless
No response	1	No response

Mild TBI: GCS 13-15, Moderate TBI: GCS 9-12, Severe TBI GCS 8 or less.
GCS can range from 3 to 15. If intubated, then verbal component is replaced by 'T'. Best possible score if intubated is 10T, and worst is 3T.
In obtunded patients, pain stimulus can be central or peripheral. In patients with suspected spinal cord injury and paralysis, central stimulus to elicit facial grimace can be used to assess motor and eye component.

BOX 2 American College of Emergency Physicians Clinical Policy Regarding Neuroimaging in Adults with Mild Traumatic Brain Injury

A noncontrast head CT is indicated (level-1 recommendation) in adults with LOC or posttraumatic amnesia only if one or more of the following is present:
- Headache
- Vomiting
- Age >60 yr
- Drug or alcohol intoxication
- Deficits in short-term memory
- Physical evidence of trauma above the clavicle
- Posttraumatic seizure
- GCS score <15
- Focal neurologic deficit
- Coagulopathy

A noncontrast head CT should be considered (level-2 recommendation) in head trauma patients with no LOC or posttraumatic amnesia if there is:
- Focal neurologic deficit
- Vomiting
- Severe headache
- Age ≥ 65 yr
- Physical signs of a basilar skull fracture
- GCS score <15
- Coagulopathy
- A dangerous mechanism (e.g., ejection from motor vehicle, pedestrian struck, fall of more than 3 feet or 5 stairs)

CT, Computed tomography; *GCS,* Glasgow Coma Scale; *LOC,* loss of consciousness.
From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, Elsevier.

- CT imaging of the head if there is a significant history of impact to the head, polytrauma, positive loss of consciousness, or stigmata of trauma to the head. The American College of Emergency Physicians Clinical Policy Regarding Neuroimaging in adults with mild TBI is summarized in Box 2.

LABORATORY TESTS

- Basic labs including CBC, basic metabolic panel, prothrombin time, activated partial thromboplastin time, urine drug screen, and ethanol blood level.
- Consider tests for platelet function analysis for unknown antiplatelet use.
- No blood biomarker currently exists. (Figs. 1 and E2)

IMAGING STUDIES (TABLE 2)

CT imaging forms the current cornerstone of imaging modalities for head trauma. Usually, in addition to a plain CT of the head (Fig. 3), CTA head/neck and CT of the spine is helpful if arterial or C-spine injury is suspected, respectively. Other imaging modalities such as MRI can be helpful in certain situations but are typically adjuncts in the acute setting to CT-guided management. Canadian CT head rules are a useful guide in determining utility of obtaining a CT scan. These are based on risk factors:

HIGH RISK:
- Failure to reach GCS of 15 within 2 hours
- Suspected open or any signs of basal skull fracture
- More than two episodes of vomiting
- Age older than 65

LOW RISK:
- Dangerous mechanism of injury or polytrauma
- Loss of consciousness lasting >30 minutes

Pathologies that can be identified with imaging are noted in the following:
- Primary extraaxial: Epidural, subdural, subarachnoid hemorrhage
- Primary intraaxial: Axonal injury, cortical contusion, intracerebral or intraventricular hemorrhage, encephalomalacia (from prior TBI or vascular insult)
- Skull fracture: Linear, depressed, open, involving frontal sinus or skull base
- Penetrating brain injury: Gunshot wounds, sharp objects resulting in parenchymal and vascular injury
- Vascular injury: Dissection, traumatic carotid-cavernous fistula (CCF), dural arteriovenous fistula (dAVF), pseudoaneurysm formation
- Secondary acute injury: Diffuse cerebral swelling/dysautoregulation (seen more commonly in children from posttraumatic hyperemia), infarction, infection from penetrating trauma, brain herniation from mass lesion or cerebral edema
- Secondary chronic injury: Hydrocephalus (posttraumatic due to disruption of normal CSF absorption pathways), encephalomalacia, CSF leak (from skull base fractures, manifests as otorrhea or rhinorrhea, leptomeningeal cyst (seen most commonly in infants, skull fracture resulting in underlying dural injury)

Rx TREATMENT

Prevention of secondary injury is the primary goal of prehospital and early in-hospital management. Most common mechanisms of secondary injury are either intracranial (ICP, hematoma) or systemic (hypoxia, hypovolemia, hypotension). Early categorization of head trauma patients according to the severity (based on GCS) and transport to facilities equipped with personnel and technology to deal with issues pertaining to head trauma has improved the overall management of head injury patients and prevention of secondary injury. Airway, breathing, and circulation, however, still remain the most important parameters to be stabilized and both directly and indirectly affect GCS and overall outcome. Trauma guidelines suggest intubation should be performed in any patient

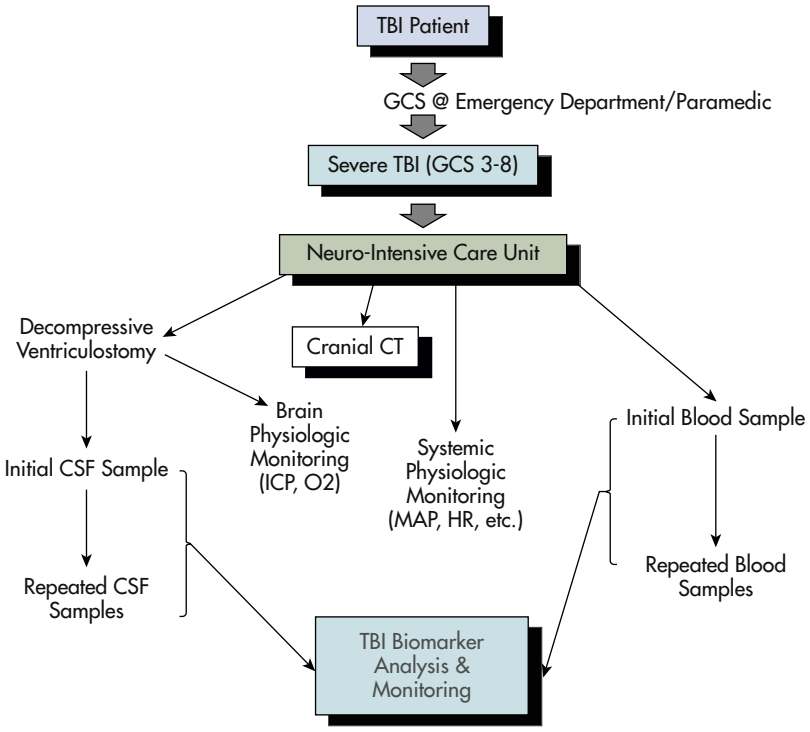

FIG. 1 Envisioned uses of brain biomarkers for severe traumatic brain injury *(TBI)* patient management. *CSF,* Cerebrospinal fluid; *CT,* computed tomography; *GCS,* Glasgow Coma Scale; *HR,* heart rate; *ICP,* intracranial pressure; *MAP,* mean arterial blood pressure. (From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.)

TABLE 2 Comparison of Head Imaging Modalities

	Computed Tomography Scans	Magnetic Resonance Imaging	Angiography	Skull Radiography
Advantages	Fast Patient accessible for monitoring Defines acute hemorrhages, mass effects, bone injuries, hydrocephalus, intraventricular blood, edema	Defines contusions and pericontusion edema, posttraumatic ischemic infarction, brainstem injuries	Helps localize acute traumatic lesions Defines vascular injuries, injuries to venous sinuses Detects mass effects	Readily available May help screen some patients for further imaging studies
Disadvantages	Artifacts arise from patient's movement, foreign bodies Streak artifacts may obscure brainstem or posterior fossa	Slow Patients not easily accessible for monitoring Does not define most acute hemorrhagic lesions Not useful for bone injuries	Does not define nature of acute lesion Does not detect infratentorial masses	Does not indicate presence or absence of intracranial injury
Indications	Acute severe head trauma Acute moderate head trauma Suspected depressed skull fracture High-risk minor head trauma Suspected child abuse in minor head trauma Deteriorating neurologic status	Persistent symptoms with postconcussive syndrome Suspected posttraumatic ischemic infarction Suspected contusions not seen on CT scan	Suspected vascular injury CT scan not available	CT scan may not be done Penetrating head trauma

CT, Computed tomography.

with a GCS of 8 or less to prevent hypoxemia and hypercapnia. Intravenous fluid resuscitation should also be started early to prevent hypovolemia resulting in hypotension, shown to double mortality. Transfer to and care in a Level I trauma center are associated with better outcomes.

Details of in-hospital management including critical care and surgical intervention is beyond the scope of this text. Some important points are summarized below.

- ATLS protocol (airway, breathing, circulation, disability, exposure).
- Ventilatory support.
- Optimization of oxygenation, ventilation, and fluid status.
- CT head (Fig. E4) to evaluate for mass lesion (hematoma) or cerebral edema. These findings may necessitate either surgical intervention or ICP monitor placement. ATLS guidelines recommend maximum 30 minutes between initial assessment and CT head.
- In case of either a severe TBI (GCS 8 or less) or a moderate TBI (GCS 8 to 13) with an unreliable neurological exam, patients should be admitted to the intensive care unit for frequent neurological checks. TBI guidelines suggest ICP monitor placement for GCS 8 or less to monitor intracranial pressure closely. ICP monitors are of various kinds, and the most commonly used include external ventricular drain, intraparenchymal pressure monitor, and a bolt device with

FIG. 3 Noncontrast-enhanced computed tomography scan of acute epidural hematoma at the level of right midconvexity. There is an associated mass effect and moderate midline shift. (From Marx JA et al: *Rosen's emergency medicine: concepts and clinical practice,* 7 ed, 2010, Elsevier.)

brain tissue oxygen pressure monitoring with fiberoptic pressure monitor. Recent research has also supported the use of brain tissue oxygen monitoring for severe TBI patients. Surgical decompression may involve evacuation of hematoma (epidural, subdural intraparenchymal contusion) through craniotomy alone (replacement of bone after completion of operation) versus decompressive craniectomy (complete removal of bone without replacement) in certain cases where cerebral edema is out of proportion to the presence of mass lesion. Skull fractures are treated depending on the morphology of the fracture. Open, depressed fractures require surgical debridement and elevation in most cases, in addition to broad-spectrum antibiotics.

- Avoid electrolyte imbalance, especially hyponatremia and hyperglycemia, which may contribute to cerebral edema and increase intracranial pressure.
- Elevation of head of bed to allow better venous drainage to reduce intracranial pressure.
- ICP management, which may include the following: Drainage of cerebrospinal fluid via external ventricular drain, surgical hematoma evacuation, administration of hyperosmotic fluids to reduce edema, pharmacologic sedation and paralysis, pentobarbital-induced coma, and surgical decompression of the brain. Decompressive craniectomy in patients with TBI and refractory intracranial hypertension results in lower mortality and higher rates of vegetative state, lower severe disability, and upper severe disability than medical care.[23] In patients with traumatic brain injury, hypothermia can reduce intracranial hypertension, but recent trials in patients with an intracranial pressure of more than 20 mm Hg after TBI, therapeutic hypothermia, plus standard care to reduce intracranial pressure did not result in outcomes better than those with standard care alone. The new TBI guidelines do not recommend hypothermia.
- Prevention of seizures in the acute setting. The most commonly used and studied drug is phenytoin. Indications for acute seizure prophylaxis in severe head trauma are described in Box 3. Levetiracetam (Keppra) is also a beneficial antiepileptic now commonly used in the TBI setting. Seizure prophylaxis, however, has not shown to prevent long-term development of traumatic epilepsy.
- DVT prophylaxis is recommended in almost all patients on hospital day 1 in addition to sequential compression devices (SCDs) for immobile or bedbound patients to prevent DVTs.
- Early initiation of parenteral nutrition.
- Early tracheostomy for ventilator-dependent patients is recommended to reduce mechanical ventilation days.

BOX 3 Indications for Acute Seizure Prophylaxis in Severe Head Trauma

- Depressed skull fracture
- Paralyzed and intubated patient
- Seizure at the time of injury
- Seizure at emergency department presentation
- Penetrating brain injury
- Severe head injury (Glasgow Coma Scale score ≤8)
- Acute subdural hematoma
- Acute epidural hematoma
- Acute intracranial hemorrhage
- Prior history of seizures

CHRONIC Rx

- TBI can lead to short- or long-term emotional, physiologic, and cognitive sequelae. Patients suffering from TBI are shown to benefit from neurocognitive, occupational, and physical therapy. The Glasgow Outcome Scale is a comprehensive measure of severity and eventual outcome of brain injury. Posttraumatic amnesia, age, length of coma, GCS score within the first 24 hours, and imaging study scales are some of the factors affecting outcome and dictating long-term prognosis.
- Chronic treatment addresses several sequelae of TBI, including, but not limited to, the following: dysautonomia, agitation, sleep disturbance, posttraumatic epilepsy, spasticity, dysphagia, syndrome of the trephined, posttraumatic hydrocephalus, apathy, fecal/urinary incontinence, headache, and neuropathic pain syndromes.
- Neurostimulants such as amantadine, zolpidem, bromocriptine, amphetamine, and methylphenidate are used in the rehabilitation phase with anecdotal data, but good RCTs are lacking in this area.

DISPOSITION

Depending on severity of head injury, patients may require admission to a rehabilitation facility or discharge to home with outpatient neurocognitive therapy.

REFERRAL

Early transfer to a Level 1 Trauma Center with neurosurgical personnel if high-risk findings are noted on clinical exam or CT head, and is associated with better outcomes.

PEARLS & CONSIDERATIONS

TBI is major healthcare issue. Guidelines have been developed to address TBI in a timely and effective fashion. Clinical acumen and judgment, however, is irreplaceable and should be exercised for better patient care and outcomes. Early recognition of high-risk patients and early imaging and early evaluation at a Level 1 Trauma Center by a specialist are associated with improved outcomes. The goal of healthcare providers in the field or in the community is to identify patients who need this attention.

BASIC INFORMATION

DEFINITION

Traveler diarrhea (TD) is defined as 3 or more loose-to-watery stools, with or without associated fever, abdominal cramps, and vomiting, within a 24-hr period. It develops during or within 10 days of traveling to developing areas of the world.

SYNONYMS

TD
Enterotoxigenic *E. coli*
Enteroaggregative *E. coli*
Infectious diarrhea
Postinfectious irritable bowel syndrome

ICD-10CM CODE
A09 Infectious diarrhea

EPIDEMIOLOGY & DEMOGRAPHICS

Traveler diarrhea is mostly caused by bacteria and other pathogens in food and water.

At least 1 episode of diarrhea occurs in 40% to 50% of travelers during their stay abroad. Table 1 describes pathogens and epidemiologic features associated with traveler diarrhea.

INCIDENCE: High risk (>20%): South and Southeast Asia, Africa (except South Africa), South and Central America, and Mexico

Moderate risk (10% to 20%): Caribbean Islands, South Africa, Central and East Asia (including Russia and China), Eastern Europe, and the Middle East, including Israel

Low risk (<10%): Northern and Western Europe, Australia, New Zealand, United States, Canada, Singapore, Japan

PEAK INCIDENCE:

- Peak incidence occurs during the first week of travel and progressively declines after that
- Seasonal variation does exist for TD, with lower rates in the winter months

PREVALENCE: Acute and chronic diarrhea account for a third of medical visits by returned travelers as per the GeoSentinel database.

PREDOMINANT SEX AND AGE:

- Travelers in their 30s are at highest risk, possibly secondary to more adventurous travel.
- Gender does not seem to influence the risk for TD.
- Infants and toddlers are more likely to have a more severe form of TD and are more likely to need hospitalization.

GENETICS: Travelers with the O blood group are at higher risk for diarrhea caused by Norovirus and *Shigella*.

RISK FACTORS:

- Gastric acid protects against enteropathogens, so medications that reduce gastric acid secretion (i.e., PPI or H2-receptor blockers) are known to increase risk for TD by a factor of 12.
- Immunocompromised travelers such as those with HIV/AIDS are at higher risk for parasitic infections.
- Backpackers are at higher risk than those staying at a resort.
- Food bought from street vendors or prepared by persons not wearing gloves carries a higher risk.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The clinical presentation does not allow determination of infectious cause.
- Ninety percent of cases occur within 2 weeks of stay.
- Acute watery diarrhea predominates in 90% of patients.
- Signs of invasive infection, including fever and bloody/mucoid diarrhea, occur in 3% to 30%.
- Most patients report 3 to 5 bowel movements a day, but in 20% a higher frequency of up to 20 daily bowel movements occurs.
- Nausea (10% to 70%), vomiting (4% to 36%), abdominal cramps/tenesmus (80%), urgency (90%).
- Other: Myalgia, arthralgia, headache.
- Average episode resolves in 3 to 5 days.
- Prolonged symptoms lasting more than a week: 8% to 15%; chronic diarrhea >30 days: 1% to 3%.
- Severe episodes may result in electrolyte imbalance (K+ loss).
- Fifty percent of all travelers are incapacitated for at least 24 hours, but up to 20% are ill in bed for 1 to 2 days.

ETIOLOGY

- *E. coli* (Table E2): Accounts for up to 60% of all cases of TD and is most prevalent in Central and South America, South Asia, and Africa. Table E3 summarizes etiology of traveler diarrhea in Latin America, Africa, and Asia.
  1. Enterotoxigenic *E. coli* (ETEC): Produce heat labile and heat stable toxin and are the most common cause, accounting for 10% to 45% of cases. Frequently seen in Latin America, Africa, and South Asia.
  2. Enteroaggregative *E. coli* (EAEC): More commonly seen in Latin America.
  3. Other *E. coli* (enteropathogenic [EPEC], enteroinvasive [EIEC], enterohemorrhagic [EHEC]): Shiga toxin-producing or diffuse adhering *E. coli* are much less common.
- *Campylobacter:* 2% to 32% of cases. More common in Southeast Asia, where it is more frequent than ETEC.
- Shigella: 2% to 9%. More common in Africa.
- Salmonella: <5% of cases except in Asia, where it is seen in up to 10% of cases.
- Other bacteria: *Aeromonas, Arcobacter, Plesiomonas,* enterotoxigenic *Bacteroides fragilis, Vibrio cholera,* noncholera vibrios.
- Viral pathogens:
  1. Norovirus: Up to 17% of cases from Caribbean and Africa.
  2. Rotavirus: 4% to 7% of cases.
- Protozoans:
  1. *Entamoeba histolytica:* More common in South and Southeast Asia.
  2. *Giardia lamblia:* More common in South and Southeast Asia, especially Nepal.
  3. *Cryptosporidium, Cyclospora, Isospora.*

TABLE 1 Pathogens and Epidemiologic Features Associated with Traveler Diarrhea

Organism	Approximate Percentage of Cases (%)	Epidemiologic Features
Enterotoxigenic *Escherichia coli*	15-50	Most important causative agent of traveler diarrhea overall; not diagnosed by routine microbiologic methods
Enteroaggregative *E. coli*	20-35	Not diagnosed by routine microbiologic methods
Shigella spp. and enteroinvasive *E. coli*	10-25	Most important causes of dysentery; enteroinvasive *E. coli* not diagnosed by routine microbiologic methods
Nontyphoidal *Salmonella* spp.	5-10	
Campylobacter jejuni	3-15	More common in Asia; antimicrobial resistance a concern
Aeromonas	5	
Plesiomonas	5	
Giardia lamblia	<2	Affects hikers and campers who drink from contaminated freshwater streams
Cryptosporidium hominis/parvum	<2	Occasional large-scale waterborne outbreaks
Cyclospora cayetanensis	<2	
Vibrio cholerae		Ongoing outbreaks in Haiti and Zimbabwe, and endemic in many countries in Asia; rare cause of disease in travelers
Norovirus		Outbreaks on cruise ships
Entamoeba histolytica		May cause liver abscess

From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Malaria
- Dengue fever
- Influenza
- Rocky Mountain spotted fever
- Irritable bowel syndrome
- Inflammatory bowel disease
- Shellfish poisoning
- Mushroom poisoning

WORKUP

- Most cases of TD are self-limiting, do not require workup, and are treated symptomatically without regard to etiologic agent.
- In patients with diarrhea, fever, and colitic symptoms (bloody stools, cramping), a stool culture should be obtained to look for specific bacterial pathogens.

LABORATORY TESTS

- Stool culture ×3 for bacterial pathogens.
- Stool for ova and parasites to help identify protozoans. Special stains such as modified acid fast or trichrome stain may be necessary for *Cryptosporidium, Cyclospora,* and *Isospora.*
- Blood cultures in patients with systemic illness to rule out *Salmonella* species.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Fluid replacement to treat volume depletion of diarrhea is important.
- Mild cases: Alternate fluids that contain salts and fluids that contain sugars, such as broths or fruit juices. Pedialyte is effective as an over-the-counter product.
- Severe cases: Oral rehydration solution (ORS) packets are available in most pharmacies. They should be mixed with clean water to replace lost electrolytes and are used until patient is urinating regularly. An alternative home-based solution can be made with: ½ teaspoon of salt, ½ teaspoon of baking soda, and 4 tablespoons of sugar in one liter of clean water.

ACUTE GENERAL Rx

- Antisecretory agents may reduce symptoms but do not treat underlying cause:
  1. Bismuth subsalicylate: 1 dose of 525 mg (2 tablets of Pepto-Bismol) PO every 30 min up to 8 doses a day. Can reduce number of bowel movements by 50%. Dosages are available for children based on weight, and the product is available in liquid or chewable tablet form.
  2. Loperamide: 4 mg PO, then 2 mg after each loose bowel movement, not to exceed 16 mg per day. Use for up to 48 hrs. Has antisecretory and antimotility effect. Antimotility drugs should not be used in cases of bloody diarrhea or dysentery (increased risk of colitis and colonic perforation). When used, they should be given only in conjunction with antimicrobial therapy.
- Antibiotics are warranted only for moderate to severe diarrhea (i.e., >4 bowel movements a day, fever, or blood, pus, or mucus in stool. Antibiotics can reduce duration of diarrhea by 1 to 2 days.
  1. Azithromycin: The preferred antibiotic for empiric treatment of moderate to severe TD. It is also the preferred agent for children and pregnant women. Dose of 1 gram PO is the single dose for women. Children: 10 mg/kg/day single dose or for 3 days. Particularly effective against quinolone-resistant *Campylobacter* infections in Southeast Asia. Another option for children: Ceftriaxone 50 mg/kg/day IV once daily ×3 days.
     a. Ciprofloxacin: 500 mg twice a day for 1 to 3 days
     b. Levaquin: 500 mg a day for 1 to 3 days
  2. Fluoroquinolones are also effective agents for bacterial causes of TD, but resistance to fluoroquinolones is increasing. Cannot be used in children under 15 and in pregnant women:
  3. Rifaximin: 200 mg PO tid for 3 days for children age >12 and adults is effective for afebrile, noncolitic diarrhea such as ETEC. Does not treat *Salmonella, Shigella,* or *Campylobacter.*
  4. Rifamycin is now FDA approved for TD caused by non-invasive strains of *E. coli.* It is not recommended for TD complicated by fever and/or bloody stools. Dosage is 388 mg (2 tablets) bid ×3 days.
- Concerns of use of antibiotics:
  1. Widespread use of antibiotics has led to resistance. Tetracycline and sulfa agents such as Bactrim are no longer used due to widespread resistance.
  2. Antibiotic treatment may lead to prolonged colonization in infections with *Salmonella* and nontyphoid *Salmonella.*
  3. In cases of EHEC (Shiga toxin production) treatment with quinolones, but not rifaximin, may increase risk of complications such as hemolytic uremic syndrome.
  4. *Clostridia difficile* infection can occur with use of antibiotics.

PREVENTION BY ANTIBIOTICS AND NONANTIBIOTIC AGENTS

- Antibiotic prophylaxis can be considered for certain groups, such as persons with underlying illness, athletes, and politicians for up to 2 to 3 weeks. Ciprofloxacin 250 to 500 mg a day is effective in preventing 90% of TD. Rifaximin dosed daily has been shown to help prevent TD for U.S. travelers to Mexico, but not as effectively as Ciprofloxacin.
- Bismuth subsalicylate can be used. It must be given 4× daily and can cause black tongue and stools. As it contains salicylates, it can interact with anticoagulants and lead to toxicity in patients on long-term salicylate therapy.
- Probiotics are being studied for their potential use but evidence of their effectiveness is limited.

REFERRAL

Infectious diseases physician for more difficult cases lasting more than 72 hours

PEARLS & CONSIDERATIONS

- Travelers on cruises have lower incidence of TD than land-based trips, but cruise ship passengers and staff are at higher risk of large outbreaks of Norovirus that are difficult to contain. Norovirus infection needs only a low inoculum of virus to cause illness, and the virus is relatively resistant to cleaning.
- In up to 40% of cases of TD, no pathogen is identified.
- *Giardia* is the most frequent cause of long-lasting TD.

PREVENTION

- There are oral and injectable vaccines against *Salmonella typhi* available in the U.S.
- Dukoral oral vaccine is available in some countries such as Canada and Australia and in Europe to help prevent cholera and ETEC.

PATIENT & FAMILY EDUCATION

Food hygiene education: Wash hands often, especially after going to bathroom and before eating. Avoid raw fruits and vegetables (unless peeled and washed in clean water). Avoid undercooked meats, fish, and seafood. Avoid tap water and ice. Choose beverages in factory-sealed containers (such as bottled water and carbonated soft drinks). Try to avoid buffet-style foods.

BASIC INFORMATION

DEFINITION

Trichinellosis (trichinosis) is an infection by one of various species of the nematode parasite *Trichinella.*

SYNONYMS

Trichinella spiralis muscle infection
Trichinosis

ICD-10CM CODE
B75 Trichinellosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- About 90 cases were reported in the U.S. between 2008 and 2012 from 24 states and District of Columbia.
- In January 2017, 12 cases were reported in California among persons attending a dinner at which larb, a traditional Laotian raw pork dish, was served. Nine infected persons were hospitalized with sepsis and seven had acute kidney injury.
- Most cases occur outside the United States worldwide. Table E1 summarizes hosts and geographic distribution of species of the genus *Trichinella.*

GENETICS: Congenital infection:

- Abrupt delivery of stillbirths in infected pregnant women
- Vertical infection of the fetus

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms:
  1. Incubation period is usually 7 to 30 days and may vary widely depending on the time from ingestion of contaminated meat and on worm burden.
  2. Mild infections can be subclinical.
- Enteral phase:
  1. Correlates with penetration of ingested larvae into the intestinal mucosa
  2. May last from 2 to 6 wk
  3. Mild, transient diarrhea and nausea
  4. Abdominal pain
  5. Diarrhea or constipation
  6. Vomiting
  7. Malaise
  8. Low-grade fevers
- Migratory or parenteral phase:
  1. In the intestine, maturation and mating
  2. Newborn larvae:
     a. Penetrate into lymphatic and blood vessels
     b. Migrate to muscles, where they penetrate into muscle cells, enlarge, coil, and develop a cyst wall
  3. Patients may present with:
     a. Fever
     b. Myalgias
     c. Periorbital or facial edema
     d. Headache
     e. Skin rash, splinter hemorrhages under fingernails
     f. Other symptoms caused by the penetration of tissues by the newborn migrating larvae
  4. Peak in symptoms 2 to 3 wk after infection, then slowly subside
- Severe complications:
  1. Brain damage by granulomatous inflammation or occlusion of arteries
  2. Myocarditis with arrhythmias
  3. Respiratory myositis due to diaphragmatic involvement

ETIOLOGY

- *Trichinella* is a parasitic intracellular round worm. Larvae of *trichinella* species invade columnar epithelium cells of villi of the small intestine and develop into adult worms (Fig. E1).
- It is one of the most ubiquitous parasites in the world and may be found in virtually all warm-blooded animals. Most infections are due to *T. spiralis.*
- Humans are incidental hosts and infections in humans occur by the ingestion of contaminated animal meat that is raw or partially cooked and contains viable cysts.
- Most cases are now related to the consumption of poorly processed pork or wild game (bear, wild boar, cougar, and walrus).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Different presentations have different differential diagnoses.
- Early illness may resemble gastroenteritis.
- Later symptoms may be confused with:
  1. Measles
  2. Dermatomyositis
  3. Glomerulonephritis
  4. Cysticercosis
  5. Strongyloidiasis

TABLE E1 Hosts and Geographic Distribution of Species of the Genus *Trichinella*

Species	Code	Common Hosts	Geographic Distribution	Encapsulated
Trichinella spiralis	T1	Pigs, rodents, horses, bears, foxes	Worldwide	Yes
Trichinella nativa	T2	Bears, foxes, dogs	Arctic, subarctic	Yes
Trichinella britovi	T3	Dogs, cats, bears	Temperate areas, subarctic	Yes
Trichinella pseudospiralis	T4	Birds, omnivorous mammals	Arctic, Tasmania	No
Trichinella murrelli	T5	Bears	North America	Yes
Not yet defined	T6	Bears	Subarctic	Yes
Trichinella nelsoni	T7	Hyenas, cats	Tropical Africa	Yes
Not yet defined	T8	Lions, panthers	Southern Africa	Yes
Not yet defined	T9	Sylvatic carnivores	Japan	No

From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

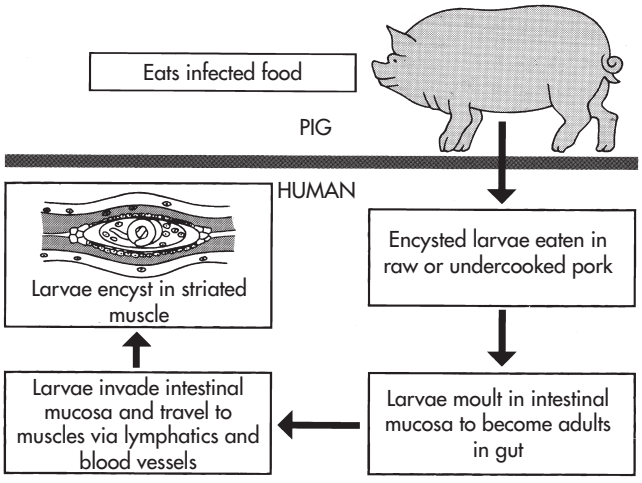

FIG. E1 Life cycle of *Trichinella spiralis.* (From Souhami RL, Moxham J: *Textbook of medicine,* ed 4, London, 2002, Churchill Livingstone.)

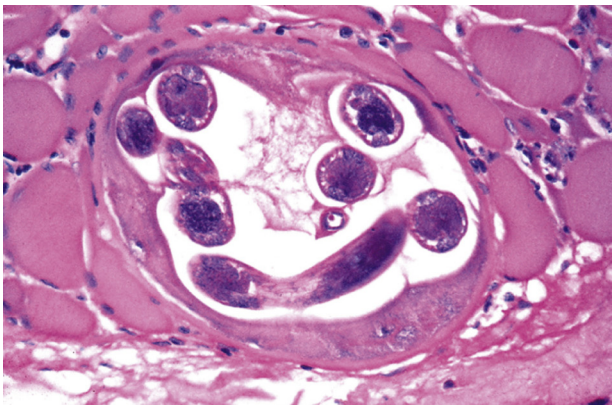

FIG. E2 Coiled *Trichinella spiralis* larvae within a skeletal muscle cell. (From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.)

WORKUP

- Antibody assay of serum is usually positive by approximately 2 to 4 wk after infection and can remain positive for years.
- Muscle biopsy is used to detect the larva in muscle tissue if diagnosis unclear; best done by placing the tissue between two slides.

LABORATORY TESTS

- Complete blood count: Leukocytosis with prominent eosinophilia (20% to 90%).
- Erythrocyte sedimentation rate: Usually normal.
- Elevation of muscle enzymes common (i.e., creatine phosphokinase, lactate dehydrogenase, aldolase).
- Serology: Antibodies detected by ELISA and Western blot but not useful in early disease.
- Muscle biopsy to look for larvae directly (Fig. E2). Biopsy is best done in symptomatic muscles and near insertion of a tendon.

IMAGING STUDIES

Soft-tissue radiographs may show calcified cyst walls.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Bed rest for myalgias

ACUTE GENERAL Rx

- Most infections are self-limited and do not require specific treatment.
- Albendazole: 400 mg twice a day for 10 to 14 days.
- Mebendazole: 200 to 400 mg tid for 3 days then 400 to 500 mg tid for 10 days but not available in the U.S.
- These agents are not advisable in pregnancy or children less than 2 yr of age.
- Steroids can be added in severe cases: Prednisone at 30 to 60 mg/day for 10 to 15 days.
- Salicylates to decrease muscle discomfort.

DISPOSITION

- Most symptoms subside over time.
- Reports of long-term sequelae:
  1. Myalgias
  2. Headaches
- Occasionally, death occurs.

REFERRAL

Diagnosis uncertain

PEARLS & CONSIDERATIONS

COMMENTS

- Prevention by thorough cooking of meats to at least 77° C (170.6° F).
- Inadequate to smoke, cure, or dry meats.
- Freezing at –15° C (–59° F) for 3 wk will kill *T. spiralis* larvae in pork.
- *T. nativa* is a freeze-resistant species that remains viable after freezing, even for months or years; it has been associated with infection from ingestion of bear meat.

Tricuspid Regurgitation PTG

BASIC INFORMATION

DEFINITION

Tricuspid regurgitation (TR) refers to an abnormal retrograde flow of blood from the right ventricle to the right atrium (Fig. E1).

SYNONYMS

TR
Tricuspid insufficiency
Tricuspid incompetence

ICD-10CM CODES

I07.1	Rheumatic tricuspid insufficiency
I07.2	Rheumatic tricuspid stenosis and insufficiency
I36.1	Nonrheumatic tricuspid (valve) insufficiency
I36.2	Nonrheumatic tricuspid (valve) stenosis with insufficiency

EPIDEMIOLOGY & DEMOGRAPHICS

- In the adult population, the principal cause of TR is usually functional rather than structural, secondary to the dilation of the right ventricle and the tricuspid annulus.
- Approximately 10% of all TR is primary.
- In adolescents and young adults, most cases of TR are the result of congenital cardiac abnormalities.
- In patients with rheumatic heart disease, TR rarely occurs alone; it is usually associated with mitral or aortic valve disease.
- Flail leaflet is uncommon but can occur with chest trauma, endomyocardial biopsy, or pacemaker insertion.
- A small degree (i.e., trace to mild) of TR is present in approximately 70% of normal adults. On echocardiography, this "normal" degree of regurgitation is localized to a small region adjacent to valve closure, it often does not extend throughout systole, and it has low signal strength.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Isolated TR can cause nonspecific symptoms (e.g., exercise intolerance).
- Signs and symptoms of TR are usually the result of an underlying cause.
- Signs and symptoms may be caused by accompanying right-sided heart failure (e.g., jugular venous distention, peripheral edema, parasternal lift, ascites, hepatomegaly, right-sided S_3).
- A lower-left parasternal holosystolic murmur may be found; the murmur becomes louder during inspiration (Carvallo sign) and during maneuvers that increase venous return such as squatting, leg lifts, and isotonic exercises.
- Prominent "c-V" wave in the jugular venous waveform can occur analogous to prominent V-wave in the Swan-Ganz catheter pressure waveform in the setting of significant MR.
- Severe TR may produce systolic propulsion of the eyeballs, pulsatile varicose veins, a venous systolic thrill and murmur in the neck, a mid-diastolic murmur in severe regurgitation, and systolic hepatic pulsation.
- Atrial fibrillation or flutter is common as a result of right atrial enlargement secondary to elevated right atrial pressure.
- Table E1 summarizes the stages of tricuspid regurgitation.

ETIOLOGY

- Tricuspid valve dysfunction can occur with structurally normal (functional TR) or abnormal valves (primary TR).
- Functional TR involves conditions that lead to the dilation of the tricuspid annulus or right ventricular enlargement, including the following:
  1. Any cause of pulmonary hypertension (e.g., chronic obstructive pulmonary disease, pulmonary embolism, restrictive lung disease, collagen vascular disease, primary pulmonary hypertension, left to right shunts [i.e., ASD, VSD, anomalous pulmonary venous return]).
  2. Left-sided heart failure that leads to right-sided heart failure (this is the most common cause of right-sided heart failure).
  3. Dilated cardiomyopathy.
  4. Right ventricular infarction.
  5. Mitral stenosis or regurgitation.
- Primary TR involves conditions directly affecting the tricuspid valve apparatus, including the following:
  1. Rheumatic heart disease
  2. Congenital conditions (e.g., Ebstein anomaly—apical displacement of tricuspid valve, tricuspid atresia, cleft valve associated with atrioventricular canal malformations—primum ASD)
  3. Ischemic heart disease involving right ventricle with papillary muscle rupture
  4. Endocarditis, either bacterial (particularly related to intravenous drug use) or marantic (e.g., systemic lupus erythematosus, rheumatoid arthritis, and adenocarcinoma)
  5. Tricuspid valve prolapse or chordae rupture
  6. Carcinoid syndrome—can also lead to tricuspid stenosis
  7. Marfan syndrome
  8. Iatrogenic damage to the valve (e.g., pacemaker, implantable cardioverter-defibrillator, endomyocardial biopsy, anorectic drugs)
  9. External trauma (e.g., deceleration injury)
  10. Right atrial myxoma
  11. Collagen vascular diseases
  12. Myxomatous degeneration associated with tricuspid valve prolapse
  13. Radiation injury
  14. Endomyocardial fibrosis (important cause in tropical Africa)
  15. Metastatic cardiac tumors such as renal cell carcinoma, etc.

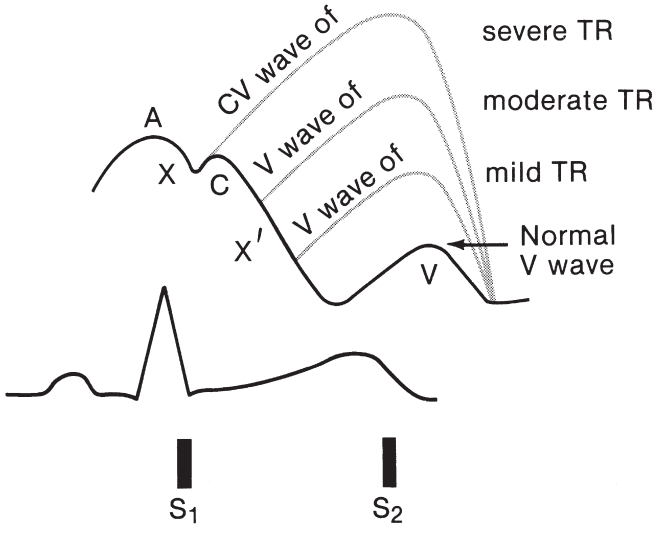

FIG. E1 The jugular venous pulse in tricuspid regurgitation. The jugular venous pulse wave normally drops during ventricular systole. As tricuspid regurgitation becomes more severe, the CV wave becomes more obvious during ventricular systole. *TR,* Tricuspid regurgitation. (From Conn R: *Current diagnosis,* ed 9, Philadelphia, 1997, Saunders.)

DIAGNOSIS

The diagnosis of TR is made noninvasively by physical examination and imaging techniques (e.g., echocardiography) and invasively by right-sided heart catheterization in selected cases.

DIFFERENTIAL DIAGNOSIS

On the basis of heart auscultation, the diagnosis of TR may be confused with other causes of systolic murmurs, such as mitral regurgitation, aortic stenosis, pulmonary stenosis, ventricular septal defect, and hypertrophic cardiomyopathy.

WORKUP

Any patient suspected of having significant TR should undergo the following:

- Chest x-ray
- ECG
- Echocardiogram (confirmatory) (Fig. E2)

TABLE E1 Stages of Tricuspid Regurgitation

Stage	Definition	Valve Anatomy	Valve Hemodynamics*	Hemodynamic Consequences	Symptoms
A	**At risk of TR**	*Primary:* Mild rheumatic change Mild prolapse Other (e.g., IE with vegetation, early carcinoid deposition, radiation) *Intraannular:* RV pacemaker or ICD lead Postcardiac transplantation (biopsy-related) *Functional:* Normal Early annular dilation	No or trace TR	None	None or in relation to other left heart or pulmonary/pulmonary vascular disease
B	**Progressive TR**	*Primary:* Progressive leaflet deterioration/ destruction Moderate to severe prolapse, limited chordal rupture *Functional:* Early annular dilation Moderate leaflet tethering	***Mild TR:*** Central jet area <5 cm^2 Vena contracta width not defined CW jet density and contour: Soft and parabolic Hepatic vein flow: Systolic dominance **Moderate TR:** Central jet area 5-10 cm^2 Vena contracta width not defined, but <0.70 cm CW jet density and contour: Dense, variable contour Hepatic vein flow: Systolic blunting	***Mild TR:*** RV/RA/IVC size normal **Moderate TR:** No RV enlargement No or mild RA enlargement No or mild IVC enlargement with normal respirophasic variation Normal RA pressure	None or in relation to other left heart or pulmonary/pulmonary vascular disease
C	**Asymptomatic severe TR**	*Primary:* Flail or grossly distorted leaflets *Functional:* Severe annular dilation (>40 mm or 21 mm/m^2) Marked leaflet tethering	***Severe TR:*** Central jet area >10 cm^2 Vena contracta width >0.7 cm CW jet density and contour: Dense, triangular with early peak Hepatic vein flow: Systolic reversal	RV/RA/IVC dilated with decreased IVC respirophasic variation Elevated RA pressure with "*c-V*" wave Diastolic interventricular septal flattening may be present	None, or in relation to other left-heart or pulmonary/pulmonary vascular disease
D	**Symptomatic severe TR**	*Primary:* Flail or grossly distorted leaflets *Functional:* Severe annular dilation (>40 mm or >21 mm/m^2) Marked leaflet tethering	***Severe TR:*** Central jet area >10 cm^2 Vena contracta width >0.70 cm CW jet density and contour: Dense, triangular with early peak Hepatic vein flow: Systolic reversal	RV/RA/IVC dilated with decreased IVC respirophasic variation Elevated RA pressure with "*c-V*" wave Diastolic interventricular septal flattening Reduced RV systolic function in late phase	Fatigue, palpitations, dyspnea, abdominal bloating, anorexia, edema

CW, Continuous-wave; *ICD,* implantable cardioverter-defibrillator; *IE,* infective endocarditis; *IVC,* inferior vena cava; *RA,* right atrium; *RV,* right ventricle; *TR,* tricuspid regurgitation.
*Several valve hemodynamic criteria are provided for assessment of TR severity, but not all criteria for each category are present in every patient. Classification of TR severity as mild, moderate, or severe also depends on image quality and integration of these parameters with clinical findings.
From Nishimura RA et al: 2014 AHA/ACCF guideline for the management of patients with valvular heart disease: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol* 63:e57, 2014.

- Right-sided heart catheterization (in selected cases)
- CMR (in selected cases)

LABORATORY TESTS

ECG may show evidence of the following:
- Right atrial enlargement (e.g., P-wave amplitude in leads II or III or aVF of >2.5 mV)
- Right ventricular enlargement or hypertrophy (e.g., R:S ratio >1 in V_1, R >7 mm in V_1, or R wave in V_1+, S wave in V_5, or V_6 >10.5 mm)
- Right axis deviation—mean QRS axis between 100 and 270 degrees
- Atrial fibrillation

IMAGING STUDIES

- A chest x-ray may show the following:
  1. Evidence of chronic obstructive pulmonary disease (e.g., flattened diaphragms, barrel chest, dilated pulmonary arteries, increased retrosternal air space) or restrictive lung disease
  2. Enlarged right atrium
  3. Enlarged right ventricle
  4. Enlarged/prominent pulmonary arteries
- An echocardiogram (either transthoracic or transesophageal) will do the following:
  1. Distinguish primary from functional TR

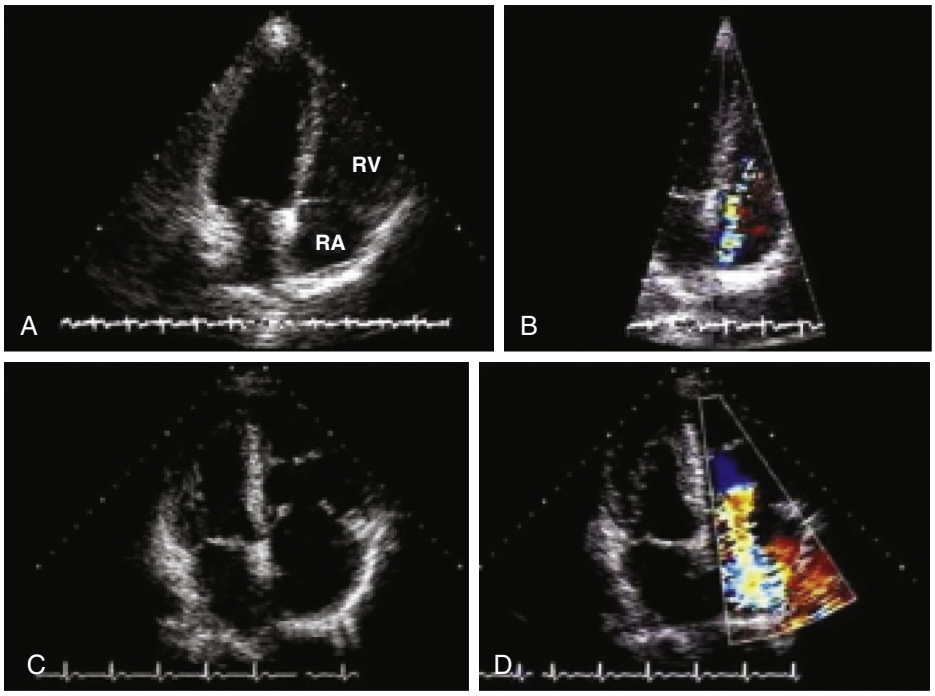

FIG. E2 Tricuspid regurgitation (TR) caused by carcinoid involvement of the tricuspid valve. Serial two-dimensional echocardiograms **(A** and **C)** and color Doppler studies **(B** and **D)** separated by 3 years are shown. **C,** After 3 years, severe thickening and fixation of the tricuspid leaflets are evident, with consequent severe TR and associated right ventricle *(RV)* and right atrial *(RA)* enlargement. (From Møller JE et al: Factors associated with progression of carcinoid heart disease, *N Engl J Med* 348:1005, 2003. In Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.)

2. Assess tricuspid valve structure and motion, measure annular size, and identify other cardiac abnormalities. Transesophageal echocardiogram is not typically needed since the tricuspid valve is an anterior structure easily assessed on transthoracic echocardiogram. Right ventricle, right atrium, and tricuspid annulus are often dilated in moderate to severe TR. 3D echocardiography can be helpful in analyzing complex valve anatomy and when tethering from a pacemaker or ICD lead is suspected
3. Estimate the severity of TR (vena contracta width >0.7 cm and systolic flow reversal in hepatic veins)
4. Estimate the pulmonary artery pressure
5. Exclude vegetation, mass, or prolapse
6. Assess left and right ventricular function

- CMR (cardiovascular magnetic resonance):
  1. If echocardiographic evaluation is poor
  2. Quantitative measurements of TR volume and regurgitant fraction
  3. RV volumes
  4. RV systolic function and ejection fraction
- Right-sided heart catheterization shows the following:
  1. Elevated right atrial and right ventricular systolic and end-diastolic pressures
  2. Large c-V waves

Rx TREATMENT

The treatment of TR is usually directed at the underlying cause.

NONPHARMACOLOGIC THERAPY

Oxygen therapy is beneficial for patients with functional TR caused by underlying pulmonary hypertension provoked by alveolar hypoxia.

ACUTE GENERAL Rx

- Severe TR with right-sided heart failure is typically treated with loop diuretics and aldosterone antagonists.
- In functional TR with left-sided heart failure, treatment should be targeted to the underlying disease process. If left ventricular systolic dysfunction is present, treatment includes standard therapies of preload reduction, afterload reduction, and inotropic therapy (see "Heart Failure").
- Improvement in functional TR can be seen with reversal of pulmonary hypertension by vasodilators, pulmonary thromboendarterectomy, or treatment of mitral stenosis. Structural TR treatment depends on the underlying cause.

CHRONIC Rx

- The American College of Cardiology/American Heart Association Guidelines Pertaining to the Surgical Management of Tricuspid Valve Disease/Regurgitation are summarized in Table E2.
- Moderate or severe TR of any cause is associated with increased mortality regardless of pulmonary artery systolic pressure or left ventricular ejection fraction.
- During recent years, annuloplasty has become an established surgical approach to significant TR. A recent study showed that tricuspid valve (TV) repair with an annuloplasty ring results in improved long-term outcomes.
- When the valve leaflet anatomy is not suitable for repair, valve replacement with a low-profile mechanical valve or bioprosthesis is often necessary. A bioprosthesis is almost always used due to the high rate of thromboembolic complications with mechanical prosthesis in the tricuspid position.
- In patients with TR due to refractory endocarditis (e.g., intravenous drug users), total excision of the diseased valve is done to eradicate the endocarditis without immediate replacement of the valve to avoid reinfection, and antibiotics are resumed. Initially, most patients tolerate the loss of the tricuspid valve without any difficulty. However, RV dysfunction usually occurs subsequently, and therefore a bioprosthetic valve may be inserted 6 to 9 mo after valve excision and control of infection.
- Some of the novel transcatheter approaches for TR that are currently under investigation include heterotopic implantation of the Edwards-Sapien XT valve in the inferior vena cava, and the use of other valve repair devices such as the MitraClip, the Mitralign or Trialign system, the TriCinch system, and the Forma spacer.

DISPOSITION

- Regardless of the cause, a greater-than-mild degree of TR is associated with decreased survival.

TABLE E2 ACC/AHA Guidelines for Intervention for Tricuspid Valve Disease[1]

Class	Indication	Loe
I	Tricuspid valve surgery is recommended for patients with severe TR (stages C and D) undergoing left-sided valve surgery.	C
	Tricuspid valve surgery is recommended for patients with severe TS at operation for left-sided valve disease.	C
	Tricuspid valve surgery is recommended for patients with isolated, symptomatic severe TS.	C
IIa	Tricuspid valve repair can be beneficial for patients with mild, moderate, or greater functional TR (stage B) at left-sided valve surgery with either tricuspid annular dilation or prior evidence of right-sided heart failure.	B
	Tricuspid valve surgery can be beneficial for patients with symptoms due to severe primary TR that are unresponsive to medical therapy (stage D).	C
IIb	Tricuspid valve repair may be considered for patients with moderate functional TR (stage B) and pulmonary artery hypertension at left-sided valve surgery.	C
	Tricuspid valve surgery may be considered for asymptomatic or minimally symptomatic patients with severe primary TR (stage C) and progressive degrees of moderate or greater RV dilation and/or systolic dysfunction.	C
	Reoperation for isolated tricuspid valve repair or replacement may be considered for persistent symptoms caused by severe TR (stage D) in patients who have undergone previous left-sided valve surgery and who do not have severe pulmonary hypertension or significant RV systolic dysfunction.	C
	Percutaneous balloon tricuspid commissurotomy might be considered in patients with isolated, symptomatic severe TS without accompanying TR.	C

LOE, Level of evidence; *RV,* right ventricular; *TR,* tricuspid regurgitation; *TS,* tricuspid stenosis.

[1]Nishimura R et al: 2013 AHA/ACCF guideline for valvular heart disease: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol* 63:e57-e185, 2014.

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

- Clinically insignificant TR can be detected by color Doppler imaging in many normal people. This is not an indication for either routine follow-up or prophylaxis against bacterial endocarditis.
- Mild and moderate TR are well tolerated during pregnancy. Women with severe TR are at higher risk for right-sided heart failure and atrial arrhythmias during pregnancy.
- Isolated TR with normal right ventricular function does not preclude an individual's involvement in competitive sports.

REFERRAL

For patients with significant symptomatic TR, a cardiology consultation is recommended.

PEARLS & CONSIDERATIONS

- TR that results from tricuspid valve prolapse is often associated with concurrent MV prolapse.
- Secondary TR commonly occurs in combination with left-sided valvular heart disease. It often does not improve, despite correction of the left-sided valve dysfunction.
- Functional tricuspid insufficiency, if left uncorrected, carries serious long-term consequences.
- Antibiotic prophylaxis for dental, gastrointestinal, or genitourinary procedures is no longer recommended for patients with only structural tricuspid valve abnormalities.
- Tricuspid annuloplasty at the time of MV surgery results in improved functional capacity without any increase in perioperative morbidity or mortality.
- If a donor heart develops TR after cardiac transplantation, tricuspid valve replacement with a biologic prosthesis is a safe, durable, and effective method of treating TR after transplantation. This allows for future endomyocardial biopsies to be performed. Mechanical valves should be avoided.
- In TR due to endocarditis in intravenous drug users, the diseased tricuspid valve is commonly excised without immediate replacement of the valve, and interval TV replacement is done 6 to 9 mo after the endocarditis has been completely treated with antibiotics to avoid re-infection of the bioprosthesis.

Tricuspid Regurgitation (Patient Information)

AUTHORS: **Reema Qureshi, MD,** and **Aravind Rao Kokkirala, MD, FACC**

SUGGESTED READING

Nishimura RA et al: AHA/ACC guideline for management of patients with valvular heart disease: a report of the American College of cardiology/American heart association Task Force on Practice guidelines, *Circulation* 129(23):e521-e643, 2014.

Tricuspid Stenosis

BASIC INFORMATION

DEFINITION

Tricuspid stenosis (TS) is an uncommon valvular pathology that is caused by the narrowing of the tricuspid valve orifice, which results in the restriction of right atrial emptying. TS is most often rheumatic in origin, and it often presents with a combination of regurgitation and stenosis.

SYNONYMS

Tricuspid valve stenosis
TS

ICD-10CM CODE
I07.0 Tricuspid stenosis

EPIDEMIOLOGY & DEMOGRAPHICS

- TS is most commonly caused by rheumatic heart disease, and it almost always occurs with associated mitral or aortic valve disease. In rheumatic heart disease, mitral and aortic valve involvement are much more common than tricuspid valve involvement.
- Carcinoid syndrome or prosthetic valve degeneration are the most common causes for TS in United States.
- Antibiotic therapy has made rheumatic heart disease and TS in the U.S. very rare.
- TS is present at autopsy in 15% of patients with rheumatic heart disease, but it is clinically significant in only 5%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Obstruction to tricuspid flow limits cardiac output and leads to elevated mean right atrial pressures even with a gradient as small as 5 mm Hg.
- As a result, most patients with significant TS have systemic venous congestion, jugular venous distention, ascites, and peripheral edema.
- Symptoms and physical examination findings usually depend on the presence and severity of concomitant mitral or aortic valve disease.
- Symptoms of right heart failure include fatigue, right upper quadrant abdominal pain (from hepatic congestion), ascites, hepatomegaly, and peripheral edema. Some complain of a fluttering discomfort in the neck caused by the tall "a" waves. The lungs are clear in isolated tricuspid stenosis, although tricuspid stenosis often coexists with mitral stenosis.
- Jugular venous distention, a prominent a wave that can sometimes approach the level of the right ventricular systolic pressure, slow rate of y descent that is barely appreciated, and palpable hepatic pulsations are noted during sinus rhythm.
- A right atrial pulsation may be palpated to the right of the sternum, and a diastolic thrill that increases with inspiration may be felt over the left sternal edge.
- An opening snap and a low-frequency diastolic murmur are best heard along the left lower sternal border of the fourth intercostal space. The murmur is softer, high-pitched, and shorter in duration as compared to mitral stenosis. The murmur is augmented by inspiration (i.e., Carvallo sign), leg raises, isotonic exercise, and squatting (all maneuvers that increase venous return to the right side of the heart).

ETIOLOGY

- Rheumatic heart disease results in the scarring of the valve leaflets starting at the leaflet tips, shortening of the chordae tendineae, and fusion of the commissures, thereby leading to the immobility of the valve leaflets and the narrowing of the tricuspid valve orifice.
- Other causes are congenital, infectious (e.g., endocarditis), metabolic, and enzymatic abnormalities (e.g., carcinoid syndrome, Whipple disease, Fabry disease); systemic rheumatic disease (Libman-Sacks endocarditis); right atrial or metastatic tumors; hypereosinophilic syndromes; and, rarely, scarring and adhesions as a result of complications of pacemaker placement. Other unusual causes include endocardial fibroelastosis and as a sequela to ergot alkaloid (methysergide or ergotamine) therapy. Most causes of tricuspid stenosis will result in tricuspid regurgitation as well.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital tricuspid atresia or stenosis, as can be seen in Noonan syndrome (autosomal dominant disorder characterized by congenital heart defects, typically pulmonary valve stenosis and ASDs)
- Right heart diastolic dysfunction: Endomyocardial fibrosis or constrictive pericarditis, restrictive cardiomyopathies (however, restrictive cardiomyopathy and constrictive pericarditis demonstrate a steep y wave descent in the right atrial pressure tracings)
- Extrinsic compression of the right ventricle: Severe pectus excavatum, massive ascites, pleural effusion, pericardial effusion, or tumor
- Obstruction of right atrial emptying: Right atrial myxoma (although myxomas are typically found in the left atrium), metastatic tumor, right atrial thrombi, or tricuspid valve vegetation (particularly in association with a permanent pacemaker lead)

WORKUP

- Echocardiography is the diagnostic test of choice to evaluate the tricuspid valve.
- ECG is recommended to look for atrial arrhythmias, atrial fibrillation, or atrial flutter as a result of an enlarged right atrium. ECG in tricuspid stenosis may show tall atrial P waves more than 2.5 mm in the inferior leads (P pulmonale) with no right ventricular hypertrophy.
- Chest x-ray, which can demonstrate enlargement of the right atrium and IVC without enlarged pulmonary artery segment.
- Right heart catheterization is an option when echocardiography cannot be used to make a definitive diagnosis. Right heart catheterization can demonstrate prominent a wave and slow rate of Y descent.

IMAGING STUDIES

- Echocardiography reveals thickening and shortening of the tricuspid valve leaflets, restricted movement of the leaflets and the leaflet tips, a reduction in the diameter of the annulus, and diastolic doming of the valve. Evidence of right atrial enlargement and dilated IVC is present in most cases. For severe TS the mean gradient is typically more than 5 mm Hg at a heart rate of 60 to 80 bpm. Lower gradients may be seen with low stroke volume, and higher gradients can occur with coexisting tricuspid regurgitation. Transesophageal echocardiography is typically not of use since the tricuspid valve is an anterior structure and is easily visualized via transthoracic echocardiogram.
- Doppler echocardiography or cardiac catheterization demonstrates a reduced tricuspid valve area (characterized as severe when <1 cm^2), prolonged pressure half-time (severe when >190ms), and a diastolic pressure gradient across the tricuspid valve (normal gradient <1 mm Hg, and TS can be diagnosed with a mean pressure gradient as low as 2 mm Hg).
- Chest radiography may reveal an enlarged right atrium, dilated superior vena cava, and azygos vein with reduced pulmonary blood volume.

TREATMENT

NONPHARMACOLOGIC THERAPY

Salt and fluid restriction is essential to decrease peripheral edema.

GENERAL Rx

- Assess and treat the underlying cause of the valvular pathology.
- Treat bacterial endocarditis with antibiotics.
- Treat right atrial thrombus obstructing RV inflow with systemic anticoagulation (typically seen with dialysis catheters).
- Treat right atrial myxoma obstructing RV inflow with surgical resection.
- Manage right atrial volume overload with loop diuretics.
- Prescribe rate-controlling atrioventricular nodal blocking agents and anticoagulants for patients with atrial arrhythmias (atrial fibrillation and atrial flutter).

CHRONIC Rx

- Symptoms of systemic venous hypertension and congestion can be controlled with diuretics and angiotensin-converting enzyme inhibitors or angiotensin receptor antagonists, along with generalized salt and fluid restriction.

- Balloon valvuloplasty or dilation of the stenosed tricuspid valve has been shown to be effective, especially in patients with transvalvular pressure gradients 3 mm Hg and above, along with valve areas less than 1.5 cm^2. Patients with clinical evidence of systemic venous hypertension and congestion should be considered for valvotomy. However, tricuspid regurgitation that is characterized as more than mild is generally considered a contraindication to valvotomy because this can further worsen the tricuspid regurgitation. Tumor masses, vegetations, and thrombi are also contraindications to valvotomy.
- Tricuspid surgery is indicated in patients with severe TS at the time of left heart surgery or in patients with isolated symptomatic severe TS (class I recommendation). TS surgery is preferred over percutaneous balloon commissurotomy given that most TS is associated with regurgitation. Also, there is lack of long-term follow-up data on patients managed by percutaneous balloon commissurotomy.
- Tricuspid valve replacement is usually preferentially done with a large bioprosthesis, though no major difference in survival or adverse events has been identified when compared with mechanical valves in long-term follow-up. The current recommendation is that the choice of prosthesis should be individualized.

DISPOSITION

The natural course of severe TS is not well known.

REFERRAL

TS may be difficult to diagnose, so consultation with a cardiologist is recommended.

PEARLS & CONSIDERATIONS

- Rheumatic heart disease accounts for >90% of stenotic tricuspid valves.
- Rheumatic TS almost always occurs in association with mitral valve disease and sometimes with aortic valve disease.
- The majority of cases present with tricuspid regurgitation or a combination of regurgitation and stenosis.

COMMENTS

Tricuspid valve replacement carries a 30-day operative morbidity and mortality rate of 5% to 7% in addition to a high risk of right heart thrombus formation. Therefore, surgical procedures are reserved for patients who are not candidates for balloon dilation techniques. Unlike patients with mitral stenosis, patients with TS typically do not report dyspnea, orthopnea, or paroxysmal nocturnal dyspnea symptoms.

Tricyclic Antidepressant Overdose

BASIC INFORMATION

DEFINITION

Tricyclic antidepressants (TCAs) are secondary or tertiary amines that have variable abilities to inhibit reuptake of neurotransmitters (norepinephrine, dopamine, and serotonin) and to be anticholinergic, antihistaminic, and sedating. These properties are important to consider when prescribing these agents and when managing an intentional or accidental overdose.

SYNONYMS

Tricyclic antidepressant intoxication or poisoning
TCA OD

ICD-10CM CODE
T43.0 Poisoning by tricyclic and tetracyclic antidepressants

EPIDEMIOLOGY & DEMOGRAPHICS

- Pharmacokinetic interactions of TCAs are often clinically important. Table E1 summarizes selected drug interactions with tricyclic antidepressants.
- Commonly used TCAs include amitriptyline, imipramine, desipramine, nortriptyline, doxepin, amoxapine, clomipramine, and protriptyline.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Cardiovascular:
- Intraventricular conduction delay (QRS prolongation)
- Sinus tachycardia
- Atrioventricular block
- Prolongation of the QT interval
- Ventricular tachycardia
- Wide complex tachycardia without P waves.
- Refractory hypotension (the most common cause of death from TCA overdose)
- Late arrhythmias or sudden death (in addition to the arrhythmias, which occur during the first 24 to 48 hr; late problems can occur up to 5 days after the overdose)
- Fig. E1 illustrates common ECG rhythm abnormalities in tricyclic overdose

Central nervous system:
- Coma
- Delirium
- Myoclonus
- Seizures

Other:
- Hyperthermia
- Ileus
- Urinary retention
- Rhabdomyolysis
- Kidney failure
- Pulmonary complications (e.g., aspiration pneumonitis)
- Life-threatening overdose exists with the ingestion of >1 g of a TCA. Among patients who reach a hospital, most deaths occur within the first 24 hr; lack of initial symptoms can be deceptive

ETIOLOGY AND PATHOGENESIS

- Mechanisms of TCA cardiovascular toxicity (Table E2).
- CNS toxicity:
  1. Cholinergic blockade is believed to cause hyperthermia, ileus, urinary retention, pupillary dilation, delirium, and coma.
  2. The mechanism of myoclonus and seizures is not fully understood.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cardiotoxicity from TCA can be confused with intoxication by drugs that cause QRS prolongation. These include class Ia antiarrhythmic agents (disopyramide, procainamide, quinidine), class Ic antiarrhythmic agents (encainide, flecainide, propafenone), cocaine, propranolol, quinine, chloroquine, neuroleptics, propoxyphene, and digoxin. Other causes of QRS prolongation include hyperkalemia, ischemic heart disease, cardiomyopathy, and cardiac conduction system dysfunction.

WORKUP

- Clinical presentation
- Knowledge of the overdose
- Although serum drug levels do not correlate well with toxicity, TCA concentration >1 mcg/ml can be life threatening; TCA concentration >3 mcg/ml is often fatal

TABLE E1 Selected Drug Interactions with Tricyclic Antidepressants

Drug	Potential Interaction
Carbamazepine	Decreased TCA plasma levels
Phenobarbital	
Rifampin	
Isoniazid	
Antipsychotics	Increased TCA plasma levels
Methylphenidate	
SSRIs	
Quinidine	
Propafenone	
Antifungals	
Macrolide antibiotics	
Verapamil	
Diltiazem	
Cimetidine	
Class I antiarrhythmics	Depression of cardiac conduction; ventricular arrhythmias
Guanethidine	Interference with antihypertensive effect
Clonidine	
Sympathomimetic amines (e.g., epinephrine)	Arrhythmias, hypertension (e.g., isoproterenol, epinephrine)
Antihypertensives	Hypotension
Vasodilator drugs	
Low-potency antipsychotics	
Anticholinergic drugs	Additive anticholinergic toxicity
MAOIs	Delirium, fever, convulsions
Sulfonylurea hypoglycemics	Hypoglycemia

MAOI, Monoamine oxidase inhibitor; *SSRI,* selective serotonin reuptake inhibitor; *TCA,* tricyclic antidepressant.
From Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

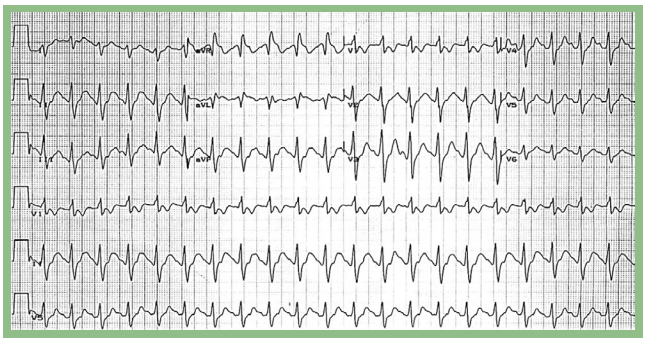

FIG. E1 Electrocardiographic findings in tricyclic antidepressant toxicity. Note the tachycardia, widened QRS interval (144 msec), and prominent R wave in lead aVR. These findings are consistent with blockade of fast sodium channels. (From Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.)

TABLE E2 Mechanism of Tricyclic Antidepressant Cardiovascular Toxicity

Toxic Effect	Mechanism
Conduction delays, arrhythmias	
QRS prolongation atrioventricular block	Cardiac sodium channel → slowed depolarization in atrioventricular node, His-Purkinje fibers, and ventricular myocardium
Sinus tachycardia	Cholinergic blockade, inhibition of norepinephrine reuptake
Ventricular tachycardia	
Monomorphic	Cardiac sodium channel inhibition → reentry
Torsades de pointes	Cardiac potassium channel inhibition → prolonged repolarization
Ventricular bradycardia	Impaired cardiac automaticity
Hypotension	
Vasodilation	Vascular alpha-adrenergic receptor blockade
Decreased cardiac contractility	Cardiac sodium channel inhibition → impaired excitation-contraction coupling

TABLE E3 Treatment of Complications of Tricyclic Antidepressant Toxicity

Toxic Effect	Treatment
Cardiovascular	
QRS prolongation	Hypertonic $NaHCO_3$ if QRS prolongation is marked or progressing; not clear if treatment is needed in the absence of hypotension or arrhythmias.
Hypotension	Intravascular volume expansion, $NaHCO_3$ vasopressors (norepinephrine) or inotropic agents (dopamine). Correct hyperthermia, acidosis, seizures. Consider mechanical support.
Ventricular tachycardia	$NaHCO_3$, lidocaine, overdrive pacing. Correct hypotension, hypothermia, acidosis, seizures.
Torsade des pointes	Overdrive pacing.
Ventricular bradycardia	Chronotropic agent (epinephrine), pacemaker.
Sinus tachycardia	Treatment rarely needed.
Atrioventricular block type II second or third degree	Pacemaker.
Hypertension	Rapidly titratable antihypertensive agent (nitroprusside).
Central Nervous System	
Delirium	Restraints, benzodiazepine. Neuromuscular blockade for hyperthermia, acidosis.
Seizures	Benzodiazepine. Neuromuscular blockade for hyperthermia, acidosis.
Coma	Intubation, ventilation if needed.
Other	
Hyperthermia	Control seizures, agitation. Cooling measures.
Acidosis	$NaHCO_3$ Correct hypotension, hypoventilation

- Baseline complete blood count, prothrombin time, blood urea nitrogen, creatinine, and electrolytes

Rx TREATMENT

ACUTE GENERAL Rx

- Initial measures:
  1. Hospitalization with cardiac monitoring as well as monitoring of vital signs and temperature.
  2. Initiate IV access.
  3. Administer activated charcoal with sorbitol.
  4. Large-bore tube gastric lavage is of unproven benefit.
  5. Ipecac is contraindicated.
  6. 12-lead ECG.
  7. If no evidence of cardiotoxicity has been noted during the first 6 hr of observation, further monitoring is not necessary; if there is evidence of cardiotoxicity, monitoring should continue for 24 hr after all signs of toxicity have resolved.
- See Table E3 for treatment of specific complications of TCA toxicity.
- Hemodialysis is not effective.
- When the patient is medically stable, psychiatric evaluation should be obtained.
- An algorithm for treatment of tricyclic antidepressant overdoses is described in Fig. E2.

AUTHOR: **Fred F. Ferri, MD**

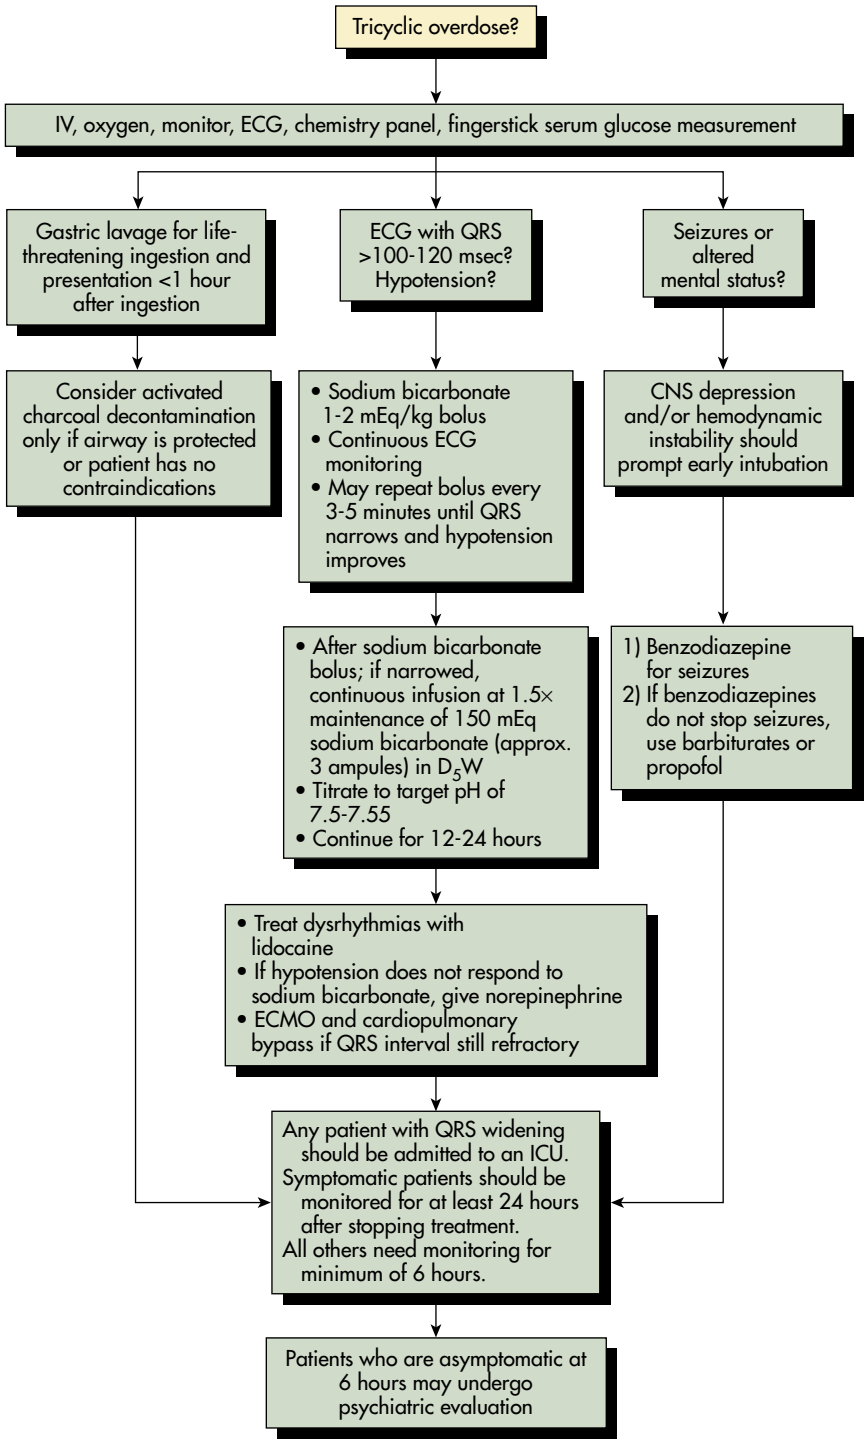

FIG. E2 Algorithm for treatment of tricyclic antidepressant overdoses. *CNS,* Central nervous system; *D5W,* 5% dextrose in water; *ECG,* electrocardiogram; *ECMO,* extracorporeal membrane oxygenation; *ICU,* intensive care unit; *IV,* intravenous. Trigeminal Neuralgia PTG

BASIC INFORMATION

DEFINITION

Trigeminal neuralgia is an intense, usually unilateral, paroxysmal, stabbing pain in the sensory distribution of the trigeminal (cranial nerve V) nerve.

SYNONYM

Tic douloureux ("painful tics/spasms")

ICD-10CM CODE
G50.0 Trigeminal neuralgia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 4 per 100,000
PEAK INCIDENCE: Incidence increases with age and peaks at 67 yr of age; onset in 90% of patients is after age 40.
PREVALENCE: 155 in 1 million
PREDOMINANT SEX AND AGE: Male:female ratio is 1:1.5.
RISK FACTORS: Most cases are idiopathic; age and multiple sclerosis are risk factors.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients present with paroxysmal, unilateral facial pain that is usually described as shock-like, stabbing, or electric (Fig. 1).
- Pain can be spontaneous or triggered by touch, an air current, or activities such as shaving, eating, or brushing teeth.
- In severe cases, facial spasms can accompany the pain.
- Pain is usually described in distribution of the second (V2-maxillary) and third (V3-mandibular) divisions of the trigeminal nerve.
- The pain seldom lasts more than a few seconds to a minute.
- There is usually no sensory or motor loss.

ETIOLOGY

- Idiopathic or "classical": Cause usually unknown, likely an aberrant artery or vein compressing cranial nerve V at or near the pons. Neurovascular contact is also commonly found incidentally on imaging in asymptomatic individuals.
- Secondary: Accounts for up to 15% of cases; caused by nonvascular lesions such as a demyelinating plaque from multiple sclerosis or compression from a tumor near the pons.
- Box 1 summarizes causes of trigeminal neuralgia.

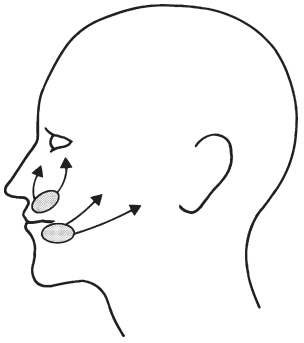

FIG. 1 Trigeminal neuralgia. The two most common sites of origin and radiation of pain are shown: mouth-ear and nose-orbit. Pain usually starts in the region of the encircled area and radiates in the directions shown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Trigeminal neuropathy
- Primary stabbing headache
- Short-lasting unilateral neuralgiform headache with conjunctival injection and tearing (SUNCT)
- Postherpetic neuralgia
- Glossopharyngeal neuralgia
- Dental pain

WORKUP

Trigeminal neuralgia is a clinical diagnosis (see previously).

IMAGING STUDIES

Neuroimaging (contrast-enhancing brain MRI) should be considered in young patients (<40 yr) with atypical symptoms (sensory loss, bilateral symptoms). MRI is useful to identify potential compressors or demyelinating causes. It detects nonvascular structure pathology in 15% of patients. Brain MRI is useful to identify neurovascular contact between trigeminal nerve and superior cerebellar artery.

TREATMENT

PHARMACOLOGIC Rx

- Carbamazepine 400 to 800 mg, 2 to 3 times daily divided dosing is the recommended initial treatment. This can be titrated to pain relief by 100 to 200 mg every 3 days to a maximum of 1200 mg divided bid or tid. HLA phenotype must be sent prior to starting in patients of East Asian ancestry due to high association with risk of Stevens-Johnson syndrome with carbamazepine.
- Oxcarbazepine can be used if carbamazepine is not tolerated due to side effects. Other medications include botulinum toxin type A, lidocaine, baclofen, phenytoin, gabapentin, clonazepam, lamotrigine, and levetiracetam.
- Drug combinations can be tried when one medication is partially effective before proceeding with secondary intervention.
- Spontaneous remissions may be seen in trigeminal neuralgia, and therefore periodic medication tapers should be considered if the patient is pain free.
- In the elderly population, caution should be used when initiating and titrating the above medications. Caution and extensive counseling should also be used in women of childbearing age when initiating treatment with anti-seizure medications.

BOX 1 Causes of Trigeminal Neuralgia

Classical
Neurovascular compression by an artery or vein

Symptomatic
Saccular aneurysm
Arteriovenous malformation
Tumors/mass-lesions at cerebellopontine angle:
- Vestibular schwannoma
- Meningioma
- Epidermoid

Primary demyelinating disorders:
- Multiple sclerosis
- Charcot-Marie-Tooth disease (rare)

Infiltrative disorders:
- Trigeminal amyloidoma

Nondemyelinating lesions:
- Small infarct or angioma in the brainstem

Familial

Modified from Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.

NONPHARMACOLOGIC THERAPY

Patients with refractory pain eventually need secondary intervention such as microvascular decompression, selective nerve fiber destruction (rhizotomy), glycerol injection, thermal lesioning, chemical ablation, or gamma knife radiosurgery. Microvascular decompression is the only available nondestructive procedure and is effective in 75% of patients, and possesses observed long-term benefits.

DISPOSITION

- Most patients are responsive to initial pharmacologic treatment. Spontaneous remission is possible.
- Medical management is eventually ineffective in 30% to 50% of patients.

REFERRAL

Referral to a neurologist is appropriate if there is uncertainty about diagnosis or if symptoms are refractory to conservative management.

PEARLS & CONSIDERATIONS

In a young patient with trigeminal neuralgia, secondary causes such as multiple sclerosis should be considered, and an MRI of the head obtained. In secondary disease, initial therapy should address underlying secondary causes.

BASIC INFORMATION

DEFINITION

Trigger finger refers to an inflammatory process involving the flexor tendon and A1 pulley that can lead to triggering of the digit. Fibroosseous pulleys along the fingers serve to tether down the flexor tendon and prevent bowstringing. Degenerative and inflammatory changes to the pulley can result in pain and difficulty flexing or extending the affected digit, as its tendon is no longer able to smoothly glide along the pulley (Fig. E1) (the fibroosseous tunnel that guides the flexor tendons of the fingers during flexion and extension). Over time, a nodule can develop on the flexor tendon at level of the A1 pulley causing a catching and popping phenomenon in patients, which can be painful and limit function. At the end stage of the condition, the patient may have to manually flex or extend the digit, as active motion is now completely limited.

SYNONYMS

Digital stenosing tenosynovitis
Stenosing flexor tenosynovitis
Stenosing tendovaginitis

ICD-10CM CODES

M65.30	Trigger finger, unspecified finger
M65.321	Trigger finger, right index finger
M65.322	Trigger finger, left index finger
M65.329	Trigger finger, unspecified index finger
M65.331	Trigger finger, right middle finger
M65.332	Trigger finger, left middle finger
M65.339	Trigger finger, unspecified middle finger
M65.341	Trigger finger, right ring finger
M65.342	Trigger finger, left ring finger
M65.349	Trigger finger, unspecified ring finger
M65.351	Trigger finger, right little finger
M65.352	Trigger finger, left little finger
M65.359	Trigger finger, unspecified little finger

EPIDEMIOLOGY & DEMOGRAPHICS

Trigger finger is one of the most common causes of hand pain in adults, with general prevalence of about 2% to 3% in the general population. Diabetics have almost a 10% lifetime risk of developing a trigger finger and tend to do worse with nonoperative management. The thumb and ring fingers are the most commonly affected digits; however, the condition can occur in any finger.
PREDOMINANT SEX AND AGE: Female:male ratio of 4:1. Trigger finger can be found in all age groups but is most commonly found in patients in the fifth and sixth decade of life.
RISK FACTOR: Most cases are spontaneous, without preceding trauma or alteration in activity level. However, some authors consider trigger finger to be associated with repetitive use occupations or jobs involving gripping or lifting. Patients with diabetes mellitus and rheumatoid arthritis are at increased risk.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Tenosynovitis of the flexor tendon always precedes the mechanical symptoms of triggering, resulting in pain over the flexor tendon around the palmar metacarpophalangeal (MCP) joint with palpation, passive finger extension, or isometric flexion.
- Triggering may be actively correctable (patient can extend finger with a click) or passively correctable (patient can extend finger using another finger or hand).
- Prolonged triggering may result in a flexion contracture at the proximal interphalangeal (PIP) joint; treatment at this stage often results in a poorer outcome.
- A palpable tender nodule may be noted just proximal to the palmar aspect of the MCP joint of the affected digit.

ETIOLOGY

Although there are many theories, there is no definitive cause of trigger finger. While most cases are idiopathic in nature, there are increased incidences in patients with diabetes, rheumatoid arthritis, and hypothyroidism, suggesting that alteration to the collagen or other components of the flexor tendon or A1 pulley may be a cause. Histologic review of the A1 pulley shows chondrocyte proliferation and an increase in matrix glycosaminoglycans, suggesting that repetitive compression of the A1 pulley and the flexor tendon may be implicated.

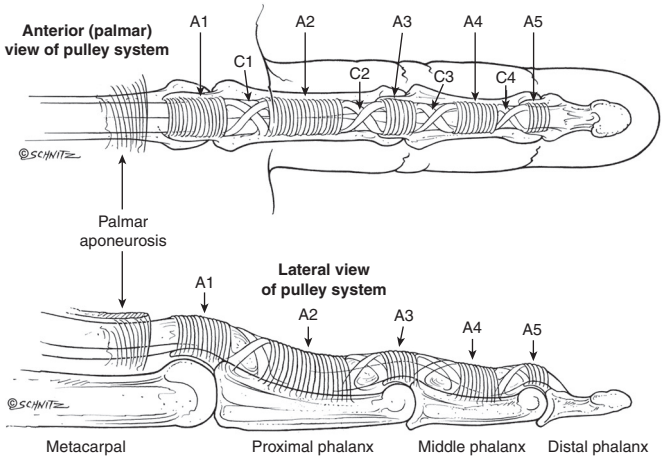

FIG. E1 The digital pulley system of the fingers. (From Ryzewicz M, Wolf JM: Trigger digits: principles, management, and complications, *J Hand Surg* 31(1):135, 2006.)

DIAGNOSIS

Based primarily on clinical history and physical examination

DIFFERENTIAL DIAGNOSIS

- Dupuytren contracture
- Infectious flexor tenosynovitis
- Proliferative tenosynovitis
- Ulnar collateral ligament injury (gamekeeper's thumb)
- Carpal tunnel syndrome
- Extensor tendon rupture
- Sagittal band rupture
- PIP contracture
- MCP arthritis
- Diabetic cheiroarthropathy

WORKUP

Rarely indicated unless an undiagnosed systemic cause (diabetes, rheumatoid arthritis, hypothyroidism) is considered or to rule out infection. It is a clinical diagnosis mostly obtained by history and physical examination.

LABORATORY TESTS

- Indicated when concerned for specific contributing factors or differential diagnosis
- Complete blood count with differential, C-reactive protein, sedimentation rate if concerned for infection
- Blood glucose, Hb^{A1c}
- Thyroid function tests
- Rheumatoid factor/anti-CCP antibody

IMAGING STUDIES

- X-rays are usually not indicated unless there is concern for fracture, foreign body, or dislocation/subluxation/erosion of a joint.
- MRI or ultrasound may be indicated for differential diagnoses of the surrounding soft tissues (e.g., ulnar collateral ligament tear).

TREATMENT

The goals of treatment are to reduce pain, swelling and inflammation in the flexor tendon sheath and allow smooth movement of the tendon when the finger is flexed or extended.

INITIAL NONOPERATIVE TREATMENT

- Rest, including ice, night splinting, or buddy taping to the adjacent finger, as much as possible for 4 to 6 wk.
- Pediatric trigger thumb responds well to intermittent extension splinting for flexible (nonfixed) deformities

- Use of gloves and damping tape to widen grips
- Physiotherapy with stretching and heat
- Oral nonsteroidal antiinflammatory medications have little supporting evidence

SUBSEQUENT NONOPERATIVE TREATMENT

- Injection of the tendon sheath or subcutaneous tissue around the sheath with a mixture of a steroid (usually triamcinolone, methylprednisolone, or betamethasone) and local anesthetic (e.g., lidocaine) is indicated for adult patients (Fig. E2). Steroid injections can transiently increase blood glucose levels in diabetic patients and are typically not as effective. Patients must be informed of this possibility before an injection is undertaken.
- If symptoms do not resolve or permanently improve, up to two repeat injections can be safe and efficacious.

SURGICAL TREATMENT

- Surgical release is indicated in patients with symptoms refractory to nonoperative care.

FIG. E2 Injection into the palm for trigger finger. (From Carr A, Hamilton W: *Orthopedics in primary care,* ed 2, Philadelphia, 2005, WB Saunders.)

- Percutaneous or open surgical release can be performed.
- Postoperative recurrence rate is about 3%.

DISPOSITION

- After steroid injection, symptoms usually resolve in 3 to 5 days, and locking resolves in most cases around 2 to 3 wk.
- If symptoms recur, one or two repeat steroid injections have a good chance to improve symptoms.
- Classically, diabetic patients have a lower success rate with steroid injections and surgical intervention compared to nondiabetic patients.

REFERRAL

Consultation with hand specialist is indicated with failure of nonsurgical management.

PEARLS & CONSIDERATIONS

COMMENTS

If more than one digit is involved, a workup for a contributing systemic disorder may be prudent.

Trochanteric Pain Syndrome (Trochanteric Bursitis) PTG

BASIC INFORMATION

DEFINITION

Greater trochanteric pain syndrome (GTPS) is a term used to describe chronic pain overlying lateral aspect of the hip. There are overlaps of trochanteric bursitis (TB) and GTPS. Unlike TB, GTPS is rarely accompanied by the principal symptoms of inflammation including erythema, edema, or warmth. GTPS often mimics pain generated from other sources such as myofascial pain, degenerative joint disease, and spinal pathology. Components of GTPS include tendinopathies and tears, bursal inflammation, and effusion.

SYNONYMS

Greater trochanteric pain syndrome
GTPS
Trochanteric bursitis
Trochanteric tendinitis

ICD-10CM CODES

M70.60 Trochanteric bursitis, unspecified hip
M70.61 Trochanteric bursitis, right hip
M70.62 Trochanteric bursitis, left hip

EPIDEMIOLOGY & DEMOGRAPHICS

- This commonly diagnosed regional pain syndrome is estimated to affect between 10% and 25% of the general population.
- In the primary care setting, the incidence of greater trochanteric pain is reported to be around 1.8 patients per 1000 per yr.
- Incidence peaks between the fourth and sixth decades of life but can occur at any age.
- Occurs more often in females than males (ratio of 4:1).
- One study found the prevalence of GTPS to be 17.6%, being higher in women and in patients with coexisting LBP, OA, ITB tenderness, and obesity.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- GTPS typically presents as chronic, persistent pain in the lateral hip and/or buttock that is exacerbated by lying on affected side, prolonged standing, driving, climbing stairs, running, or other high-impact activities.
- Pain may radiate along lateral aspect of the ipsilateral knee.
- Tenderness along the lateral or posterior aspect of the greater trochanter (Fig. E1).
- Pain can be reproduced by 10 provoking tests: Palpation of the greater trochanter, resisted external derotation test, modified resisted external derotation test, standard and modified Ober test, Patrick or FABER test, resisted hip abduction, single-leg stance test, and the resisted hip internal rotation test.

ETIOLOGY

- GTPS can be caused by repetitive high-intensity use of the tensor fasciae and gluteus medius over the outer femur trauma, infections such as tuberculosis, and crystal deposition.
- It can occur with other conditions such as osteoarthritis of the knee and hip, RA, sacroiliac joint disorders, leg length discrepancy, ankle sprain, and bunions of the feet causing changes in the patient's gait placing varus stress on the hip joint.
- It can also occur as a complication resulting from arthroscopic surgery of the hip (estimated 1.4% of cases). Cases with previous joint replacement were associated with worse outcomes.

DIFFERENTIAL DIAGNOSIS

- Piriformis tendinopathy
- L2 and L3 lumbar radiculopathy, and lumbar facet syndrome
- Iliotibial band syndrome
- Osteoarthritis of the hip
- Osteonecrosis of the hip
- Stress fracture of the femoral neck
- Meralgia paresthetica
- Acetabular labral tear
- Iliopsoas bursitis
- Osteomyelitis
- Metastatic bone disease
- Septic or pyogenic arthritis
- Gluteal medius tendon tears
- Abductor tendon tear (Table E1)

WORKUP

Since there is a wide differential for lateral hip pain, GTPS can be a challenging diagnosis to reach. Complete neurologic and musculoskeletal examination should be performed, including back, bilateral hip, knee, and observation of gait. Usually tenderness to palpation over the greater trochanter, pain with resisted abduction, and positive Patrick/FABER test are found.

LABORATORY TESTS

Not indicated in straightforward cases

IMAGING STUDIES

- Plain radiography: Plain x-rays are usually normal, but other potential causes can be excluded, including OA, femoroacetabular impingement, and fractures. Calcifications over the greater trochanter may be seen in 40% of patients presenting with GTPS.
- Ultrasound: Simple, dynamic, inexpensive test that can be very useful in establishing the cause of lateral hip pain.

FIG. E1 Typical location of pain in trochanteric bursitis syndrome. This is also a frequent pain radiation site for lumbar spine lesion, various nerve compression syndromes, and hip disease, particularly in osteonecrosis of the femoral head.

- CT and MRI will depict both osseous and soft tissue pathology but are not usually warranted unless the physician suspects associated conditions that would affect treatment decisions. MRI shows increased signal in bursitis, which can be found in symptomatic as well as asymptomatic patients.

Rx TREATMENT

Most cases of GTPS are self-limiting and tend to resolve with conservative measures.

NONPHARMACOLOGIC THERAPY

- Physical therapy and iliotibial band stretching exercises can reduce irritation of the trochanteric bursa area
- Warm compresses
- Ultrasound therapy
- Cryotherapy
- Treat gait disturbance by knee brace, shoe lift, ankle supports, and foot orthotics for the specific underlying conditions

ACUTE GENERAL Rx

- NSAIDs for pain relief: Ibuprofen 800 mg PO tid or naproxen 500 mg PO bid
- Topical corticosteroids delivered by percutaneous phonophoresis
- Corticosteroid injection
- Regional anesthetic block can be used as a treatment and may also help differentiate from referred pain

CHRONIC Rx

- Most patients respond to NSAIDs and/or nonpharmacologic therapy.
- Steroid injection: ~70% of patients respond after first injection and >90% respond after the second injection.
- Twenty-five percent of patients who receive steroid injection may experience relapse.
- A recent trial revealed that hip function improvement was greater with education plus exercise than with corticosteroid injections.[1]
- While the majority of patients with GTPS will improve with nonoperative management, endoscopic iliotibial band release and trochanteric bursectomy, with or without iliotibial band release, have shown significant benefit with minimum postoperative complications; gluteal tendon repair may also be effective treatment for severe recalcitrant cases.

REFERRAL

- Physical therapy
- Rheumatology or orthopedics referral if steroid injection therapy is indicated
- Orthopedics for possible bursectomy in chronic refractory cases

[1] Mellor R et al: Education plus exercise versus corticosteroid injection use versus a wait and see approach on global outcome and pain from gluteal tendinopathy: prospective, single blinded, randomised clinical trial, *BMJ* 361:k:1662, 2018.

TABLE E1 Trochanteric Bursitis Versus Abductor Tendon Tear

	Trochanteric bursitis	Abductor tendon tear
Symptoms	Peritrochanteric pain and tenderness to palpation over the greater trochanter Night pain	Peritrochanteric pain and tenderness to palpation over the greater trochanter Night pain
Examination	± Abductor limp ± Trendelenburg gait ± Abductor weakness	Abductor limp Trendelenburg gait Abductor weakness
MRI findings	Evidence of bursitis and increased signals at the greater trochanter Although tendinitis can be present, the tendon is intact with no tears	Tendinosis and tear of the abductor tendons with alterations in tendon signal and caliber Partial thickness and complete tears of the gluteus minimus or medius tendons
Nonoperative treatment	Walking aids (walker vs cane) NSAIDs Selective use of peritrochanteric injection with corticosteroid Structured physical therapy for strengthening	Walking aids (walker vs cane) NSAIDs Selective use of peritrochanteric injection with corticosteroid Structured physical therapy for strengthening
Operative treatment	Bursectomy (bursitis is recalcitrant to nonoperative treatment)	Tendon repair with suture anchors

MRI, Magnetic resonance imaging; *NSAID,* nonsteroidal antiinflammatory drug.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

PEARLS & CONSIDERATIONS

Patients with GTPS will commonly report "hip" pain. The physical examination readily distinguishes GTPS from other hip pathologies. Relief of pain with local corticosteroid injection is helpful in differentiating trochanteric bursitis from referred pain.

COMMENTS

- The absence of limitation in range of motion differentiates trochanteric bursitis from degenerative joint disease of the hip.
- Localization of pain over the lateral hip and thigh differentiates trochanteric bursitis from meralgia paresthetica located over the anterolateral thigh and osteoarthritis located over the inner thigh groin area.

Tropical Sprue

BASIC INFORMATION

DEFINITION

Tropical sprue is a malabsorption syndrome occurring primarily in tropical regions, including Puerto Rico, India, and Southeast Asia. The clinical features of tropical sprue include anorexia, diarrhea, weight loss, abdominal pain, and steatorrhea; these symptoms can develop in expatriates even several months after returning to temperate regions.

SYNONYMS

Postinfectious tropical malabsorption
"Tropical enteropathy," referring to a subclinical form of tropical sprue

ICD-10CM CODE
K90.1 Tropical sprue

EPIDEMIOLOGY & DEMOGRAPHICS

- Tropical sprue is endemic in tropical regions of Venezuela, Colombia, the Middle East, the Far East, the Caribbean (Puerto Rico, Haiti, Dominican Republic, Cuba), and India.
- The disease affects mainly adults, although it has been reported in all age groups.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The classic clinical features of tropical sprue are nonspecific and simply reflect the symptom of malabsorption. Onset is generally not insidious, and most patients can pinpoint when their disorder began.
- Diffuse, nonspecific abdominal tenderness and distention. Abdominal pain is crampy in nature.
- Low-grade fever.
- Glossitis, cheilosis, hyperkeratosis, hyperpigmentation (Fig. E1).
- Diarrhea, often with mucus and foul-smelling stools from fat malabsorption.
- Nausea, which leads to decreased appetite and decreased oral intake.
- Lactose intolerance often develops early in the course of tropical sprue.

ETIOLOGY

Fig. E2 illustrates the etiopathogenesis of sprue.

DIFFERENTIAL DIAGNOSIS

- Celiac disease
- Parasitic infestation
- Inflammatory bowel disease
- Other causes of malabsorption (e.g., Whipple disease)
- Lymphoma
- Pancreatic tumor
- Intestinal tuberculosis
- Microsporidia-associated HIV enteropathy

WORKUP

Diagnostic workup includes a comprehensive history (especially travel history), physical examination, laboratory evidence of malabsorption (see the following), and jejunal biopsy; the biopsy results are nonspecific, with blunting, atrophy, and even disappearance of the villi and subepithelial lymphocytic infiltration (Fig. E3). Partial villus atrophy distinguishes tropical sprue histologically from celiac sprue, which reveals flattened mucosa.

LABORATORY TESTS

- Megaloblastic anemia (>50% of cases)
- Vitamin B_{12} deficiency, folate deficiency
- Abnormal D-xylose absorption (72-hr fecal fat determination or serum carotene concentration)
- Stool examination to exclude *Giardia* spp.

IMAGING STUDIES

Gastrointestinal series with small-bowel follow-through may reveal coarsening of the jejunal folds.

FIG. E1 Hyperpigmentation of the palms in a patient with tropical sprue. This finding often is seen in southern Indian patients with tropical sprue and has been ascribed to vitamin B_{12} deficiency. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Saunders.)

TREATMENT

NONPHARMACOLOGIC THERAPY

Monitoring of weight and calorie intake

ACUTE GENERAL Rx

- Folic acid therapy (5 mg bid for 2 wk followed by a maintenance dose of 1 mg tid) will improve anemia and malabsorption in more than two thirds of patients.
- Tetracycline 250 mg qid for 4 to 6 wk in individuals who have returned to temperate zones, up to 6 mo in patients in endemic areas; ampicillin 500 mg bid for at least 4 wk in patients intolerant to tetracycline.
- Correction of vitamin B_{12} deficiency: Vitamin B_{12} 1000 mcg IM weekly for 4 wk, then monthly for 3 to 6 mo.
- Correction of other nutritional deficiencies (e.g., calcium, iron).

DISPOSITION

Complete recovery with appropriate therapy

REFERRAL

Gastrointestinal referral for jejunal biopsy

PEARLS & CONSIDERATIONS

COMMENTS

- Tropical sprue should be considered in any patient who presents with chronic diarrhea, weight loss, and malabsorption, especially if there is significant travel and exposure history.
- Important factors in the medical history in addition to travel history are use of medications that may predispose to a small-bowel overgrowth, HIV exposure (increased risk of chronic diarrhea), and any surgical procedure that may predispose to blind loop syndrome.
- Most of the functional changes in tropical sprue may be related to small-bowel mucosal damage; however, there is also dysfunctional hormonal regulation of the gut (increased enteroglucagon and motilin levels, decreased postprandial insulin and gastric inhibitory peptide), and decreased ability of the colon to absorb water.
- Even with prolonged therapy relapses can occur; however, some may be attributable to reexposure to an infecting organism rather than relapsing disease.

AUTHOR: **Fred F. Ferri, MD**

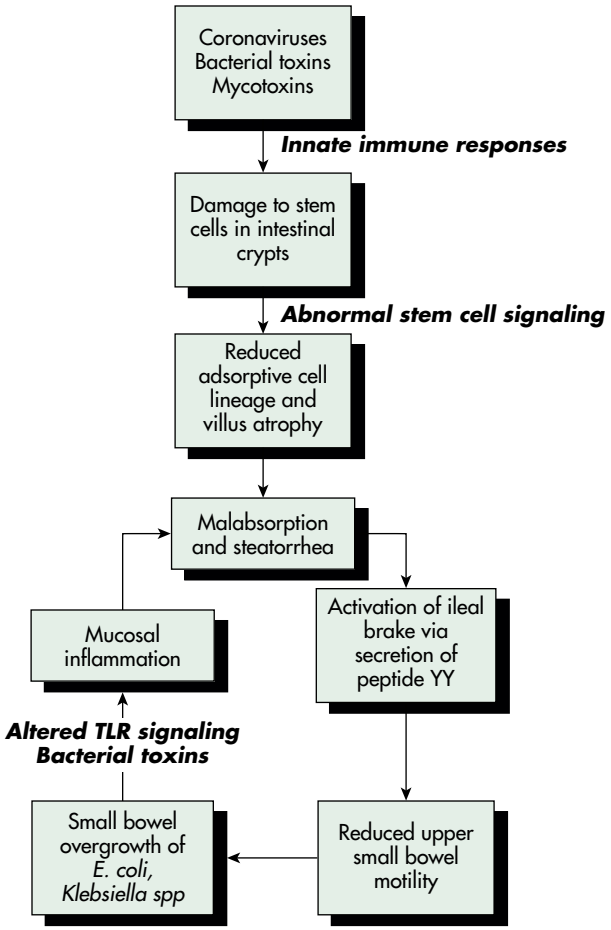

FIG. E2 Etiopathogenesis of sprue. This figure summarizes our current understanding of how etiologic agents that target intestinal epithelial stem cells lead to mucosal damage and malabsorption. This is perpetuated by small intestinal bacterial colonization because of ileal production of peptide YY, with resultant small bowel dysmotility. *TLR,* Toll-like receptor. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

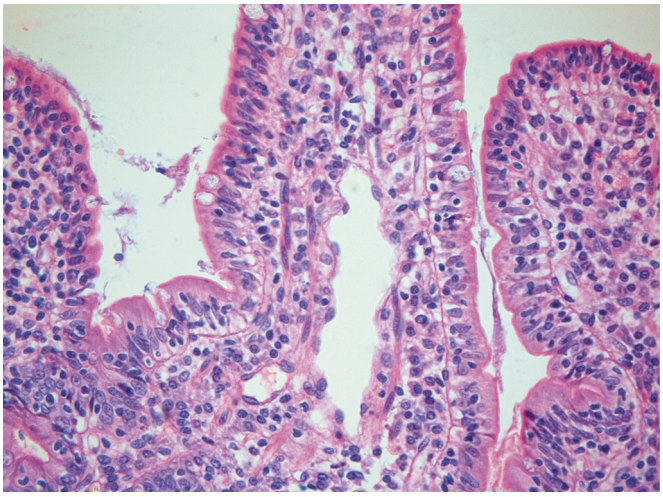

FIG. E3 Small intestinal mucosal biopsy from a patient with tropical sprue, showing an increase in intraepithelial lymphocytes. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

Tuberculosis, Miliary

BASIC INFORMATION

DEFINITION

Miliary tuberculosis (TB) is an infection of disseminated hematogenous disease, caused by the bacterium *Mycobacterium tuberculosis* (Mtb), and is often characterized as resembling millet seeds on pathologic or radiologic examination. Extrapulmonary disease may occur in virtually every organ site.

SYNONYM

Disseminated TB

ICD-10CM CODE
A19.9 Miliary tuberculosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): More than 38% of AIDS patients with TB have disseminated disease, often with concurrent pulmonary and extrapulmonary active sites. (See "Tuberculosis, Pulmonary" in Section I.)

PREVALENCE (IN U.S.):

- Undetermined
- Highest prevalence:
  1. AIDS patients
  2. Minorities
  3. Children
  4. Foreign-born persons
  5. Elderly

PREDOMINANT SEX:

- No specific predilection
- Male predominance in AIDS, shelters, and prisons reflected in disproportionate male TB incidence

PREDOMINANT AGE: Predominantly among 24 to 45 yr

PEAK INCIDENCE: HIV-positive patients, regardless of age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- See also "Etiology"
- Common symptoms:
  1. High intermittent fever (93%)
  2. Night sweats (79%)
  3. Weight loss (85%)
  4. Dyspnea (64%)
  5. Cough (82%)
- Symptoms referable to individual organ systems may predominate:
  1. Meninges
  2. Pericardium
  3. Liver
  4. Kidney
  5. Bone
  6. GI tract
  7. Lymph nodes
  8. Serous spaces:
     a. Pleural
     b. Pericardial
     c. Peritoneal
     d. Joint
  9. Skin
  10. Lung: Cough, shortness of breath
- Adrenal insufficiency possible, caused by infection of adrenal gland
- Pancytopenia:
  1. With fever and weight loss *or*
  2. Without other localizing symptoms or signs *or*
  3. With only splenomegaly
- TB hepatitis:
  1. Tender liver
  2. Obstructive enzymes (alkaline phosphatase) elevated out of proportion to minimal hepatocellular enzymes (SGOT, SGPT) and bilirubin
- TB meningitis:
  1. Gradual-onset headache
  2. Minimal meningeal signs
  3. Malaise
  4. Low-grade fever (may be absent)
  5. Sudden stupor or coma
  6. Cranial nerve VI palsy
- TB pericarditis:
  1. Effusions resembling TB pleurisy
  2. Cardiac tamponade
- Skeletal TB:
  1. Large joint arthritis (with effusions resembling TB pericarditis)
  2. Bone lesions (especially ribs)
  3. Pott disease:
     a. TB spondylitis, especially of lower thoracic spine
     b. Paraspinous TB abscess
     c. Possible psoas abscess
     d. Frequent cord compression (often relieved by steroids)
- Genitourinary TB:
  1. Renal TB:
     a. Papillary necrosis
     b. Destruction of renal pelvis
     c. Strictures of upper third of ureters
     d. Hematuria
     e. Pyuria with misleading bacterial cultures
     f. Preserved renal function
  2. TB orchitis or epididymitis:
     a. Scrotal mass
     b. Draining abscess
  3. Chronic prostatic TB
- GI TB:
  1. Diarrhea
  2. Pain
  3. Obstruction
  4. Bleeding
  5. Especially common with AIDS
  6. Bowel lesions:
     a. Circumferential ulcers
     b. Short strictures
     c. Calcified granulomas
     d. TB mesenteric caseous adenitis
     e. Abscess, but rare fistula formation
     f. Often difficult to distinguish from granulomatous bowel disease (Crohn disease)
- TB peritonitis:
  1. Fluid resembles TB pleurisy
  2. Purified protein derivative (PPD) often negative
  3. Tender abdomen
  4. Doughy peritoneal consistency, often with ascites
  5. Peritoneal biopsy indicated for diagnosis
- TB lymphadenitis (scrofula):
  1. May involve all node groups
  2. Common adenopathies:
     a. Cervical
     b. Supraclavicular
     c. Axillary
     d. Retroperitoneal
  3. Biopsy generally needed for diagnosis
  4. Surgical resection of nodes may be necessary
  5. Especially common with AIDS
- Cutaneous TB:
  1. Skin infection from autoinoculation or dissemination
  2. Nodules or abscesses
  3. Tuberculids (possibly allergic reactions)
  4. Erythema nodosum
- Miscellaneous presentations:
  1. TB laryngitis
  2. TB otitis
  3. Ocular TB:
     a. Choroidal tubercles
     b. Iritis
     c. Uveitis
     d. Episcleritis
  4. Adrenal TB
  5. Breast TB

ETIOLOGY

- See also "Tuberculosis, Pulmonary" in Section I.
- Mtb, a slow-growing, aerobic, nonspore-forming, nonmotile, acid-fast bacillus.
- Humans are the only reservoir for Mtb.
- Pathogenesis:
  1. Mtb are ingested by macrophages in alveoli, then transported to regional lymph nodes where spread is contained.
  2. Some Mtb reach the bloodstream and disseminate widely.
  3. Immediate active disseminated disease may ensue or a latent period may develop.
  4. During latent period, T-cell immune mechanisms contain infection in granulomas until later reactivation occurs as a result of immunosuppression or other undefined factors in conjunction with reactivated pulmonary TB or alone.
- Miliary TB may occur as a consequence of the following:
  1. Primary infection: Inability to contain primary infection leads to a hematogenous spread and progressive disseminated disease.
  2. In late chronic TB and in those with advanced age or poor immunity, a continuous seeding of the blood may develop and lead to disseminated disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Widespread sites of possible dissemination associated with myriad differential diagnostic possibilities:

- Lymphoma
- Typhoid fever

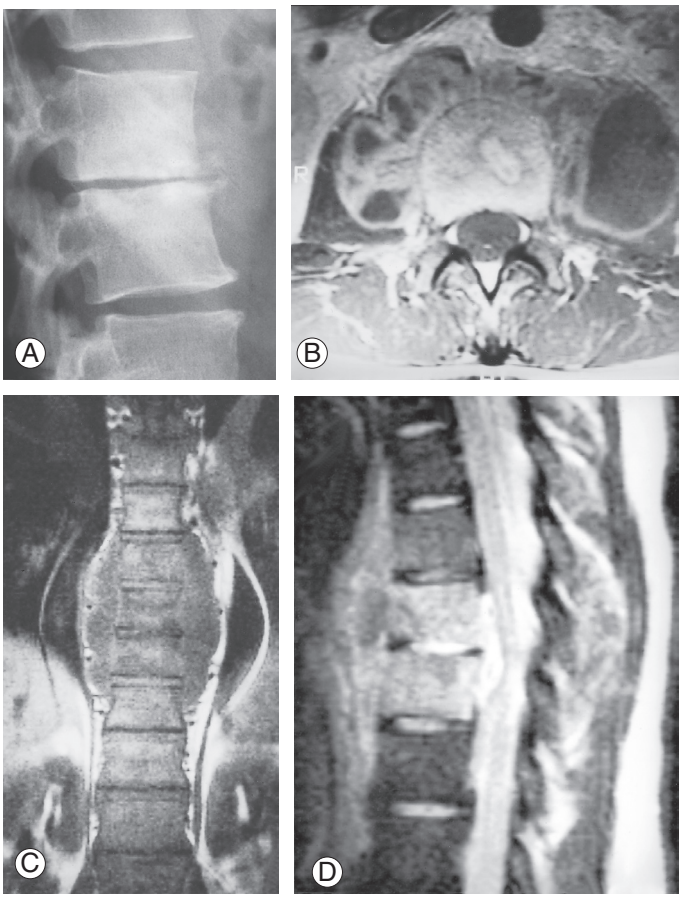

FIG. E1 Tuberculous discitis. (A) The plain x-ray changes are similar to a normal discitis with end-plate irregularity and reactive sclerosis. **(B)** Axial T1-weighted image shows the end-plate defect as well as psoas abscesses with central necrosis. **(C)** Coronal image in a different patient demonstrates intervertebral disc destruction at the point of maximal paraspinal widening and associated vertebral body signal change. **(D)** With fat suppression there is increased SI in adjacent vertebral bodies together with anterior and posterior masses (the latter compressing the spinal cord). (From Sutton D: *Textbook of radiology and imaging,* ed 7, 1998, Churchill Livingstone. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

- Brucellosis
- Other tumors
- Collagen-vascular disease

WORKUP

- Prompt evaluation is essential.
- Sputum for acid-fast bacilli (AFB) stain and culture and chest x-ray.
- High-resolution CT is more sensitive for miliary TB than CXR.
- Fluid analysis and mycobacterial culture wherever available.
  1. Sputum
  2. Blood: Particularly helpful in patients with AIDS
  3. Urine
  4. CSF
  5. Pleural
  6. Pericardial
  7. Peritoneal
  8. Gastric aspirates
- Biopsy of any involved tissue is advisable to make immediate diagnosis.
  1. Transbronchial biopsy preferred and easily accessible
  2. Bone marrow
  3. Lymph node
  4. Lumbar puncture for cerebrospinal fluid evaluation
  5. Scrotal mass if present
  6. Any other involved site
  7. Positive granuloma or AFB on biopsy specimen is diagnostic
- Imaging studies as needed (Fig. E1).

LABORATORY TESTS

- Culture and fluid analysis as described previously.
- Smear-negative sputum often is positive weeks later on culture (especially in HIV).
- CBC is usually normal.
- ESR is usually elevated.
- While not FDA approved for use in the U.S., internationally, assays to detect Mtb cell wall lipoarabinomannan in the urine (urine LAM assay) are used in HIV-infected patients with signs/symptoms of TB and CD4 <100 or severe illness.

IMAGING STUDIES

- Chest x-ray examination (may or may not be positive) (see "Tuberculosis, Pulmonary" in Section I)
- CT scan or MRI of brain and spinal cord (Fig. E2):
  1. Tuberculoma
  2. Basilar arachnoiditis
- Imaging of other sites based on clinical suspicion of involvement

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Bed rest or limited physical activity during acute phase of treatment
- High-calorie, high-protein diet to reverse malnutrition and enhance immune response to TB
- Isolation in negative-pressure rooms with high-volume air replacement and circulation (with health care provider wearing proper protective 0.5- to 1-micron filter respirators):
  1. Until three consecutive sputum AFB smears are negative or at least 2 weeks on multidrug treatment, if pulmonary disease coexists
  2. Isolation not required for closed-space TB infections such as peritonitis, osteomyelitis, and scrofula

ACUTE GENERAL Rx

- See "Tuberculosis, Pulmonary" in Section I.
- Therapy should be initiated immediately. Do not wait for definitive diagnosis.
- More rapid response to chemotherapy by disseminated TB foci than cavitary pulmonary TB.
- The American Thoracic Society/Centers for Disease Control and Prevention guidelines (2016) recommend 6 to 9 mo of treatment in patients with drug-susceptible acute TB. A four drug regimen is given for 2 mo followed by isoniazid and rifampin daily for 4 mo.
  1. Treatment for 12 mo often required for bone and renal TB.
  2. Prolonged treatment often required for CNS and pericardial.
  3. Prolonged treatment often required for all disseminated TB in infants.
- Compliance (rigid adherence to treatment regimen) is the chief determinant of success.
  1. Supervised directly observed therapy (DOT) is recommended for all patients.
  2. Supervised DOT is mandatory for patients at high risk of loss to follow-up.
- Steroids may be helpful in fulminant miliary disease with the hypoxemia and disseminated intravascular coagulation (DIC).

CHRONIC Rx

- Generally not indicated beyond treatment described previously
- Prolonged treatment supervised by infectious disease expert required in a few complicated infections caused by resistant organisms

DISPOSITION

- Monthly follow-up by physician experienced in TB treatment
- Confirm sensitivity testing, and alter treatment appropriately (see "Tuberculosis, Pulmonary" in Section I)

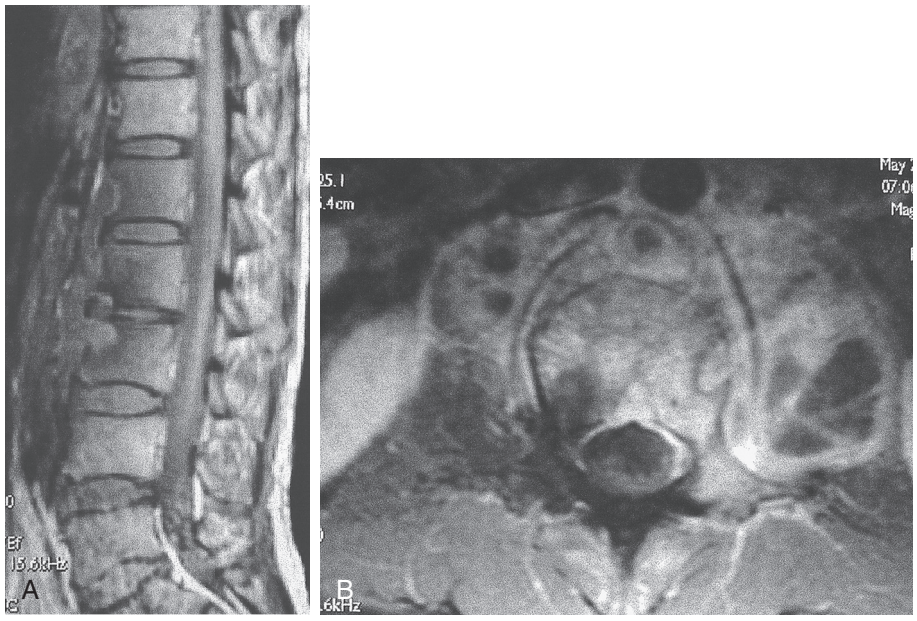

FIG. E2 A and **B,** Magnetic resonance images of tuberculous spinal osteomyelitis with scalloping of the vertebrae (tuberculous caries) and paraspinal "cold" abscesses. (From Grainger RG, Allison D: *Grainger & Allison's diagnostic radiology, a textbook of medical imaging,* ed 4, London, 2001, Churchill Livingstone.)

REFERRAL

- To infectious disease expert for extrapulmonary disease
- To pulmonary, orthopedic, or GI physicians for examinations or biopsy

PEARLS & CONSIDERATIONS

COMMENTS

- Consider acute TB in critically ill patients with enigmatic acute respiratory distress syndrome, shock, or DIC.
- All contacts (especially close household contacts and infants) should be properly tested for PPD conversions >3 mo following exposure.
- Those with positive PPD should be evaluated for active TB and properly treated or given prophylaxis.

BASIC INFORMATION

DEFINITION

Pulmonary tuberculosis (TB) is an infection of the lung and, occasionally, surrounding structures, caused by the bacterium *Mycobacterium tuberculosis* (Mtb). Multidrug-resistant (MDR) TB is defined as disease caused by strains of Mtb that are at least resistant to treatment with isoniazid and rifampin (two of the most effective first-line drugs); extensively drug-resistant (XDR) TB refers to disease caused by MDR strains that are also resistant to treatment with any fluoroquinolone and any of the injectable drugs used in second-line anti-TB treatment regimens.

SYNONYM

TB

ICD-10CM CODES
A15.0 Tuberculosis of lung
A15.7 Primary respiratory tuberculosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (WORLDWIDE):

- One fourth of the world's population is infected with TB, and it is still one of the deadliest diseases known to humans.
- In 2017, there were an estimated 10 million new cases of active tuberculosis; 9% involved coinfection with HIV; 1.3 million deaths from TB, including 300,000 among HIV-infected patients; 457,560 incident cases of multidrug-resistant TB worldwide.

INCIDENCE (IN U.S.):

- In 2018, a total of 9,029 new TB cases were reported in the U.S., representing a 0.7% decrease from 2017. The U.S. TB incidence in 2018 was 2.8 per 100,000 persons.
- The rate among non–U.S.-born persons was >14 times that in the U.S.-born persons.[1] Since 1993, TB case counts and rates have declined in the U.S (Fig. E1). As the number of cases decreases overall, an increasing percentage of cases occurs among non-U.S. born persons.
- More than 90% of new cases each yr from reactivated prior infections, while 9% represent new infections.
- Only 10% of patients with purified protein derivative (PPD) conversions will develop TB, most within 1 to 2 yr, though this is higher in HIV-positive patients (8%/yr).
- Two thirds of all new cases in racial and ethnic minorities and 80% of new cases in children occur in racial and ethnic minorities.
- Occurs most frequently in geographic areas and among populations with highest AIDS prevalence.
  1. Urban blacks and Hispanics between 25 and 45 yr old.
  2. Poor, crowded urban communities.
- Two thirds of new TB cases in 2018 occurred in non–U.S.-born persons, where the top five countries of birth were Mexico, the Philippines, India, Vietnam, and China.
- In 2017 in the U.S., 1.9% of cases were MDR TB, which is a decline from 8.2% in 2008. There were three cases of XDR TB in the U.S. in 2017.

PREVALENCE (IN U.S.):

- Between 3.1% and 5.0% of the U.S. population is estimated to be infected with latent TB infection
- Varies widely among population groups

PREDOMINANT SEX:

- Globally, in 2017, 6 million men contracted TB compared to 3.2 million women
- Male predominance in AIDS, shelters, and prisons reflected in disproportionate male incidence (Box 1)

PREDOMINANT AGE:

- Ages 24 to 45
- Childhood cases common among minorities
- Nursing home outbreaks among elderly

PEAK INCIDENCE:

- Infancy
- Teenage yr
- Pregnancy
- Elderly
- HIV-positive patients at highest risk regardless of age

BOX 1 High-risk Groups for Tuberculosis Infection and Disease

Groups at High Risk for Exposure or Infection
Close contacts of persons with tuberculosis
Foreign-born persons from high-risk regions (Asia, Africa, Latin America, Russia, eastern Europe)
Residents and employees of high-risk congregate settings (correctional institutions, nursing homes, homeless shelters, hospitals serving high-risk populations, drug treatment centers)
Medically underserved, low-income populations
High-risk racial or ethnic minority populations
Injectable drug users
Children exposed to adults in high-risk categories

Groups at Higher Risk for Disease Once Infected
Immunosuppressed patients, including those with HIV
Patients with recent tuberculosis infection (within past 2 yr)
Persons with certain medical conditions (diabetes mellitus, silicosis, cancer, end-stage renal disease, gastrectomy, body weight ≤90% of ideal)
Injectable drug users
History of inadequately treated tuberculosis
Children age ≤4 yr, especially infants

From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

GENETICS:

- Populations with widespread low native resistance have been intensely infected when initially exposed to TB.
- Following elimination of those with least native resistance, incidence and prevalence of TB tends to decline.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- See "Etiology"
- Primary pulmonary TB infection generally asymptomatic
- Reactivation pulmonary TB:
  1. Fever
  2. Night sweats
  3. Cough
  4. Hemoptysis
  5. Scanty nonpurulent sputum
  6. Weight loss
  7. Chest pain
- Progressive primary pulmonary TB disease: Same as reactivation pulmonary TB
- TB pleurisy:
  1. Pleuritic chest pain
  2. Fever
  3. Shortness of breath
- Rare massive, suffocating, fatal hemoptysis secondary to erosion of pulmonary artery within a cavity (Rasmussen aneurysm)
- Chest examination:
  1. Not specific
  2. Usually underestimates extent of disease
  3. Rales accentuated following a cough (posttussive rales)

ETIOLOGY

- Mtb, a slow-growing, aerobic, non-spore-forming, nonmotile bacillus, with a lipid-rich cell wall:
  1. Lacks pigment
  2. Produces niacin
  3. Reduces nitrate
  4. Produces heat-labile catalase
  5. Mtb staining, acid-fast and acid-alcohol fast by Ziehl-Neelsen method, appearing as red, slightly bent, beaded rods 2 to 4 microns long (acid-fast bacilli [AFB]), against a blue background
  6. Polymerase chain reaction (PCR) to detect <10 organisms/ml in sputum (compared with the requisite 10,000 organisms/ml for AFB smear detection)
  7. Culture:
     a. Growth on solid media (Löwenstein-Jensen; Middlebrook 7H11) in 2 to 6 weeks
     b. Growth in liquid media (BACTEC, using a radioactive carbon source for early growth detection) often in 9 to 16 days
     c. Enhanced in a 5% to 10% carbon dioxide atmosphere
  8. DNA fingerprinting (based on restriction fragment length polymorphism [RFLP]):
     a. Facilitates immediate identification of MTB strains in early growing cultures
     b. False negatives possible if growth suboptimal

[1]Colangeli R et al: Bacterial factors that predict relapse after tuberculosis therapy, *N Engl J Med* 379:823-833, 2018.

9. Humans are the only reservoir for Mtb
10. Transmission:
    a. Aerosolized droplets containing AFB generated through cough, speaking, singing, bronchoscopy, or autopsy are inhaled directly into alveoli
    b. Facilitated by close exposure to high-velocity cough (unprotected by proper mask or respirators) from patients with AFB-positive sputum and cavitary lesions.
    c. Locations of increased TB transmission risk include hospitals, homeless shelters, correctional facilities, nursing homes, and residential homes for those with HIV

- Pathogenesis:
  1. Mtb are ingested by macrophages in alveoli, then transported to regional lymph nodes, where spread is contained
  2. Some Mtb may reach bloodstream and disseminate widely
  3. Primary TB (often asymptomatic, minimal pneumonitis in lower or midlung fields, with hilar lymphadenopathy) is essentially an intracellular infection, with multiplication of organisms continuing 2 to 12 weeks after primary exposure, until cell-mediated hypersensitivity (detected by positive skin test reaction to tuberculin PPD) matures, and results in subsequent containment of infection
  4. Local and disseminated Mtb are thus contained by the following T-cell–mediated immune responses:
     a. Recruitment of monocytes
     b. Transformation of lymphocytes with secretion of lymphokines
     c. Activation of macrophages and histiocytes
     d. Organization into granulomas, where Mtb may survive within macrophages (Langhans giant cells), but within which multiplication essentially ceases (95%) and from which spread is prohibited
  5. Progressive primary pulmonary disease:
     a. May immediately follow the asymptomatic phase:
     b. Necrotizing pulmonary infiltrates
     c. Tuberculous bronchopneumonia
     d. Endobronchial TB
     e. Interstitial TB
     f. Widespread miliary lung lesions
  6. Postprimary TB pleurisy with pleural effusion:
     a. Develops after early primary infection, although often before conversion to positive PPD
     b. Results from pleural seeding from a peripheral lung lesion or rupture of lymph node into pleural space
     c. May produce a large (sometimes hemorrhagic) exudative effusion (with polymorphonuclear cells early, rapidly replaced by lymphocytes), frequently without pulmonary infiltrates
     d. Generally resolves without treatment
     e. Portends a high risk of subsequent clinical disease, and therefore must be diagnosed and treated early (pleural biopsy and culture) to prevent future catastrophic TB illness
     f. May result in disseminated extrapulmonary infection
  7. Reactivation pulmonary TB:
     a. Occurs months to yr following primary TB
     b. Preferentially involves the apical posterior segments of the upper lobes and superior segments of the lower lobes
     c. Associated with necrosis and cavitation of involved lung, hemoptysis, chronic fever, night sweats, weight loss
     d. Spread within lung occurs via cough and inhalation
  8. Reinfection TB:
     a. May mimic reactivation TB
     b. Ruptured caseous foci and cavities, which may produce endobronchial spread
  9. Mtb in both progressive primary and reactivation pulmonary TB:
     a. Intracellular (macrophage) lesions (undergoing slow multiplication)
     b. Closed caseous lesions (undergoing slow multiplication)
     c. Extracellular, open cavities (undergoing rapid multiplication)
     d. INH and rifampin are bactericidal in all three sites
     e. Pyrazinamide (PZA) especially active within acidic macrophage environment
     f. Extrapulmonary reactivation disease also possible
  10. Rapid local progression and dissemination in infants with devastating illness before PPD conversion occurs
  11. Most symptoms (fever, weight loss, anorexia) and tissue destruction (caseous necrosis) from cytokines and cell-mediated immune responses
  12. Mtb has no important endotoxins or exotoxins
  13. Granuloma formation related to tumor necrosis factor (TNF) secreted by activated macrophages

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Necrotizing pneumonia (anaerobic, gram-negative)
- Histoplasmosis
- Coccidioidomycosis
- Melioidosis
- Interstitial lung diseases (rarely)
- Cancer
- Sarcoidosis
- Silicosis
- Rare pneumonias:
  1. *Rhodococcus equi* (cavitation)
  2. *Bacillus cereus* (50% hemoptysis)
  3. *Eikenella corrodens* (cavitation)

WORKUP

- Sputum for AFB stains and Mtb culture.
- Chest x-ray (Fig. E2).
- PPD (tuberculin skin test [TST]) or interferon gamma release assays (IGRA) can be used for baseline testing:
  1. Recent conversion from negative to positive within 3 months of exposure is highly suggestive of recent infection.
  2. Single positive PPD is not helpful diagnostically.
  3. Negative PPD never rules out acute TB.
  4. Be certain that positive PPD does not reflect "booster phenomenon" (prior positive PPD may become negative after several yr and return to positive only after second repeated PPD; repeat second PPD within 1 wk), which thus may mimic skin test conversion.
  5. Positive PPD reaction is determined as follows:
     a. Induration after 72 hours of intradermal injection of 0.1 ml of 5 TU-PPD.
     b. 5-mm induration if HIV-positive (or other severe immunosuppressed state affecting cellular immune function), close contact of active TB, fibrotic chest lesions.
     c. 10-mm induration if in high–medical risk groups (immunosuppressive disease or therapy, renal failure, gastrectomy, silicosis, diabetes), foreign-born high-risk group (Southeast Asia, Latin America, Africa, India), low socioeconomic groups, IV drug addict, prisoner, health care worker.
     d. 15-mm induration if low risk.
  6. Anergy antigen testing (using mumps, *Candida,* tetanus toxoid) may identify patients who are truly anergic to PPD and these antigens, but results are often confusing. Not recommended.
  7. Patients with TB may be selectively anergic only to PPD.
  8. PPD cannot distinguish between TB disease and TB infection.
- Interferon gamma release assays (IGRAs): Diagnostic test for latent TB infection, known as the QuantiFERON TB Gold test (QFT-G) and T-SPOT.TB Assay. These blood tests measure interferon response to specific Mtb antigens. The test may assist in distinguishing true positive reactions from individuals with latent TB, from PPD reactions related to nontuberculous mycobacteria; prior BCG vaccination; or difficult-to-interpret skin-test results from people with dermatologic conditions or immediate allergic reactions to PPD. IGRAs have a specificity >95% for diagnosis of latent TB. The sensitivity of the T-SPOT assay (90%) appears to be higher than the QFT-G test (80%). It should be noted that IGRA sensitivity is diminished by HIV infection. Negative tests do not rule out active TB disease, and positive tests cannot distinguish between TB infection and disease.
- The Xpert MTB/RIF is an automated molecular test for Mtb and resistance to rifampin

(RIF) that provides sensitive detection of TB and rifampin resistance directly from untreated sputum in less than 2 hours with minimal hands-on time.

LABORATORY TESTS

- Sputum for AFB stains and culture:
  1. Induced sputum if patient not coughing productively
- Sputum from bronchoscopy if high suspicion of TB in patients unable to produce expectorated induced sputum for AFB:
  1. Positive AFB smear is essential before or shortly after treatment to ensure subsequent growth for definitive diagnosis and sensitivity testing
  2. Consider lung biopsy if sputum negative, especially if infiltrates are predominantly interstitial
- AFB stain-negative sputum may grow Mtb subsequently (especially in HIV)
- Gastric aspirates may be helpful, especially in children
- CBC:
  1. Variable values:
     a. WBCs: Low, normal, or elevated (including leukemoid reaction: >50,000)
     b. Normocytic, normochromic anemia often
  2. Rarely helpful diagnostically
- ESR usually elevated
- Thoracentesis:
  1. Exudative effusion:
     a. Elevated protein
     b. Decreased glucose
     c. Elevated WBCs (polymorphonuclear leukocytes early, replaced later by lymphocytes)
     d. May be hemorrhagic
  2. Pleural fluid usually AFB-negative
  3. Pleural biopsy often diagnostic—may need to be repeated for diagnosis
  4. Culture pleural biopsy tissue for AFB
- Bone marrow biopsy is often diagnostic in difficult-to-diagnose cases, especially miliary TB

IMAGING STUDIES

- Chest x-ray:
  1. Primary infection reflected by calcified peripheral lung nodule with calcified hilar lymph node
  2. Reactivation pulmonary TB:
     a. Necrosis
     b. Cavitation (especially on apical lordotic views)
     c. Fibrosis and hilar retraction
     d. Bronchopneumonia
     e. Interstitial infiltrates
     f. Miliary pattern
     g. Many of the previous findings may also accompany progressive primary TB
  3. TB pleurisy:
     a. Pleural effusion, often rapidly accumulating and massive
  4. TB activity not established by single chest x-ray examination
  5. Serial chest x-ray examinations are excellent indicators of progression or regression

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Increased rest during acute phase of treatment
- High-calorie, high-protein diet to reverse malnutrition and enhance immune response to TB
- Isolation in negative-pressure rooms with high-volume air replacement and circulation, with health care provider wearing proper protective 0.5- to 1-micron filter respirators, until three consecutive sputum AFB smears are negative during workup (taken in 8- to 24-hour intervals, with at least one being an early morning specimen) or a diagnosed case has been on standard multidrug treatment for at least 2 weeks and is clinically improving

ACUTE GENERAL Rx

- Generally, treatment of active tuberculosis consists of two phases: an intensive phase, followed by a continuation phase
- Compliance (rigid adherence to treatment regimen) chief determinant of success:
  1. Supervised directly observed therapy (DOT) recommended for all patients and mandatory for patients with high likelihood of loss to follow-up
- Adult initial regimen:
  1. Isoniazid 5 mg/kg (INH; max 300 mg), rifampin 10 mg/kg (RIF; max 600 mg), ethambutol by weight increments (EMB; 40 to 55 kg, 800 mg; 56 to 75 kg,1200 mg; 76 to 90 kg, 1600 mg), and pyrazinamide by weight increments (PZA; 40 to 55 kg, 1000 mg; 56 to 75 kg, 1500 mg; 76 to 90kg, 2000 mg) dosed daily
  2. Pyridoxine (vitamin B_6, 25 mg/day) should be given with INH to prevent peripheral neuropathy
  3. Usually decreased to INH and RIF after 8 weeks depending on susceptibilities, with ultimate duration of therapy dependent on HIV treatment status, extent of disease, regimen used, and treatment response, but generally at least 6 months
  4. Alternative, more complicated DOT regimens
- Monitor for clinical toxicity (especially hepatitis)
  1. Patient and physician awareness that anorexia, nausea, right upper quadrant pain, and unexplained malaise require immediate cessation of treatment
  2. Evaluation of liver function testing:
     a. Minimal SGOT/SGPT elevations without symptoms generally transient and not clinically significant
- Drug resistance (often multiple drug resistance TB [MDRTB]) increased by:
  1. 1 Prior treatment
  2. Acquisition of TB in high-TB-burden countries
  3. Homelessness, incarceration
  4. AIDS, intravenous drug use
  5. Known contact with MDRTB
- Other medications used in MDR or XDR TB include levofloxacin, moxifloxacin, cycloserine, aminoglycosides such as amikacin or kanamycin, PAS, clofazimine, bedaquiline, delaminid, pretomanid, linezolid, and ethionamide. A recent trial[2] with the combination of bedaquiline, pretomanid, and linezolid revealed a favorable outcome at 6 months after the end of therapy in a high percentage of patients with highly drug-resistant forms of TB
- Drug-resistant TB should be treated in consultation with a TB expert
- Preventive treatment for PPD conversion only (infection without disease):
  1. Must be certain that chest x-ray examination is negative and patient has no symptoms of TB
  2. Most important groups:
     a. HIV-positive and other severely immunocompromised patients
     b. Close contact with active TB
     c. Recent converter
     d. Old TB on chest x-ray examination
     e. IV drug addict
     f. Medical risk factor
     g. High-risk foreign country
     h. Homeless
     i. Box 2 summarizes persons in whom preventive therapy should be initiated to prevent progression to tuberculosis
  3. Treatment of **latent *M. tuberculosis***
- Infants generally given prophylaxis immediately if recent contact with active TB (even if infant PPD negative), then retested with PPD in 3 months (continuing INH if PPD becomes positive and stopping preventive treatment if PPD remains negative)

CHRONIC Rx

- Generally not indicated beyond treatment described previously

DISPOSITION

- Monthly follow-up by physician experienced in TB treatment.
- Confirm sensitivity testing and alter treatment appropriately.
- Frequent sputum samples until culture is negative.
- Confirm chest x-ray regression at 2 to 3 months.
- Approximately 5% of patients with drug-susceptible TB have a relapse after 6 months of first-line therapy. Higher MIC values of isoniazid or rifampin in predominant isolates of *M. tuberculosis* are associated with a greater risk of relapse.[3]

REFERRAL

- To infectious disease expert for:
  1. HIV-positive patient
  2. Patient with suspected drug-resistant TB
  3. Patients previously treated for TB

[2]Conradie F et al: Treatment of highly drug-resistant pulmonary tuberculosis, *N Engl J Med* 382:893-902, 2020.

[3]Talwar A et al: Tuberculosis-United States, 2018, *MMWR* 68(11):257-262, 2019.

BOX 2 Persons in Whom Treatment Should Be Initiated to Prevent Progression to Tuberculosis

Household members and other close associates of persons with potentially infectious tuberculosis
- Contacts of any age with a Mantoux tuberculin skin test reading of 5 mm or greater and no documented history of reaction in the past, or with a positive interferon gamma release assay (IGRA), should be considered recently infected and receive therapy if they have not been treated previously
- Newly infected people, regardless of age, who have had a tuberculin skin test or IGRA conversion within the past 2 yr
- People with HIV infection who have a reaction of 5 mm or greater to a Mantoux test or positive IGRA
- People of any age with past tuberculosis infection who received inadequate treatment
- People of any age with a positive tuberculin skin test or positive IGRA and an abnormal but stable chest radiograph
- People with significant tuberculin reactions or positive IGRAs who have special clinical situations, including silicosis, diabetes mellitus, prolonged corticosteroid therapy, immunosuppressive therapy, hematologic malignant disease, or end-stage renal disease
- All children and adolescents with a positive tuberculin skin test reaction or interferon release assay result

Adapted from Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

4. Patients whose fever has not decreased and sputum has not converted to negative in 2 to 4 weeks
5. Patients with overwhelming pulmonary or extrapulmonary TB

- To pulmonologist for bronchoscopy or pleural biopsy

PEARLS & CONSIDERATIONS

COMMENTS

- All contacts (especially close household contacts and infants) should be properly tested for PPD conversions during 3 months following exposure.
- Those with positive PPD should be evaluated for active TB and properly treated or given prophylaxis.
- Previous treatment is a common risk factor for XDR and MDR TB.
- In treatment of latent TB infections, evidence exists for the efficacy and safety of 6-month isoniazid monotherapy, rifampicin monotherapy, and combination therapies with 3 to 4 months of isoniazid and rifampicin.[4]
- Left untreated, 5% to 10% of patients with latent TB develop active TB. Updated guidelines from the CDC and the National Tuberculosis Controllers Association[5] for latent TB treatment include any of the following regimines:

1. Once-weekly isoniazid plus rifapentine for 3 mo administered under direct observation. The guideline recommends this regimen for adults and children (age < 2 yr), including patients who are HIV-positive.
2. Daily rifampin for 4 mo is also recommended strongly, especially for HIV-negative people, and perhaps has the lowest toxicity.
3. Daily rifampin plus isoniazid for 3 mo is another alternative.

BASIC INFORMATION

DEFINITION

Tuberous sclerosis (TS) is an inherited neurocutaneous disorder that is characterized by pleomorphic features involving many organ systems, including multiple benign neoplasms (hamartomas) of the brain, kidney, and skin.

SYNONYMS

TS
TSC
Tuberous sclerosis complex

ICD-10CM CODE
Q85.1 Tuberous sclerosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: TS has an estimated incidence of 1 case per 6000 live births. Thus, it is the second most common neurocutaneous syndrome after neurofibromatosis.
PREVALENCE: The disorder affects about 1 in 10,000 persons in the general population.
PREDOMINANT SEX: TS has no predilection for gender or race.
GENETICS:

- TS is an autosomal dominant disorder with almost complete penetrance but a wide range of clinical severity. However, only one third of cases are familial. The apparently nonfamilial cases can represent either spontaneous mutations or mosaicism.
- Genetic research has identified two TS genes. One is located on chromosome 9 (*TSC1* gene) and the other on chromosome 16 (*TSC2* gene). About 68% of cases occur as a result of new gene mutations. Because of the genetic transmission and new mutations, antenatal diagnosis is difficult.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Dermatologic manifestations (Figs. E1, E2, and E3) may be the only clues the family physician has to the diagnosis of the disorder, which is also marked by childhood seizures and mental retardation.
- The diagnostic criteria for TS were recently revised at a consensus conference. Major and minor features are listed in Table E1.
- The classic diagnostic triad of seizures, mental retardation, and facial angiofibromas (Fig. E4) (Vogt triad) occurs in fewer than 50% of patients with TS.
- All of the clinical features of TS may not be apparent in the first yr of life. Thus, a child is often initially diagnosed with possible or probable TS, and the diagnosis of definite TS is made after additional features are identified.
- Dermatologic manifestations: A careful skin examination of patients at risk for TS continues to be the easiest and most accessible method of establishing the diagnosis (Table E2).
- Neurologic manifestations: These are the leading cause of morbidity and mortality in patients with TS. Brain hamartomas in the form of cortical tubers, subependymal nodules, and subependymal giant cell astrocytomas are often responsible for intractable seizures, most commonly as infantile spasms. Approximately 90% to 96% of TS patients have seizures. Approximately 85% of patients have their first epileptic episode in the first 2 yr of life. Behavioral and cognitive dysfunction, including autism and mental retardation, can be seen in 40% to 50% of patients.
- Renal and pulmonary manifestations are strongly associated with TS.
- Angiomyolipoma is the most common renal lesion found in TS patients. Clinically evident pulmonary involvement in TS patients is relatively rare, with an estimated incidence of 1% to 6%. The most common lesion is lymphangiomyomatosis (LAM), a progressive cystic lung disease with progressive dyspnea and spontaneous pneumothorax in a childbearing woman.
- Cardiovascular manifestations: These are often the earliest diagnostic findings in patients with TS. Rhabdomyoma is the most common primary cardiac tumor in infants and children. Its incidence in TS patients ranges between 47% and 60%. In fact, 80% to 95% of patients with cardiac rhabdomyomas have TS.
- The most common ocular findings in TS are retinal hamartomas, appearing in 40% to 50% of patients.

ETIOLOGY

TS is an autosomal dominant disorder.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cutaneous manifestations:

- Nevus anemicus
- Nevus depigmentosus (nevus achromicus)
- Vitiligo

FIG. E1 A hypopigmented, ash leaf-shaped spot on the thigh of a patient with tuberous sclerosis. (From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

FIG. E2 A periungual fibroma in a patient with tuberous sclerosis. (From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

FIG. E3 An erythematous plaque representative of a connective tissue nevus in a patient with tuberous sclerosis. (From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

TABLE E1 Revised Diagnostic Criteria for Tuberous Sclerosis Complex (TSC)

Major Features

1. Facial angiofibromas or forehead plaque
2. Nontraumatic ungual or periungual fibroma
3. Hypomelanotic macule (three or more)
4. Shagreen patch (connective tissue nevus)
5. Multiple retinal nodular hamartomas
6. Cortical tuber
7. Subependymal nodule
8. Subependymal giant cell astrocytoma
9. Cardiac rhabdomyoma, single or multiple
10. Lymphangiomyomatosis
11. Renal angiomyolipoma

Minor Features

1. Multiple, randomly distributed pits in dental enamel
2. Hamartomatous rectal polyps
3. Bone cysts
4. Cerebral white matter radial migration lines
5. Gingival fibromas
6. Nonrenal hamartomas
7. Retinal achromic patch
8. "Confetti" skin lesions
9. Multiple renal cysts

Definite TSC: Either two major features or one major feature plus two minor features. Probable TSC: One major plus one minor feature. Possible TSC: Either one major feature or two or more minor features.

WORKUP

- The dermatologic manifestations of TS are helpful in diagnosing this disorder. When TS has been inherited in the autosomal dominant form, dermatologic signs are almost universally present in one of the patient's parents.
- No specific prenatal laboratory test is available.
- Early recognition of TS is vital because prompt implementation of the recommended diagnostic evaluation (neuroimaging studies, EEG, ECG, renal ultrasonography, brain MRI [Fig. E5] and chest CT) may prevent serious clinical consequences.
- Some findings in TS complex (TSC), notably renal angiomyolipomas and pulmonary lymphangioleiomyomatosis (LAM) emerge later, placing adults with undiagnosed TSC at increased risk for morbidity and mortality.

LABORATORY TESTS

- Molecular genetic testing: In recent yr, molecular genetic testing for TS has become clinically available. Such testing identifies mutations in the *TSC1* and *TSC2* genes by one of several methods, most commonly polymerase chain reaction (PCR) amplification of individual exons followed by DNA sequencing on DNA obtained from a patient's blood sample.
- DNA testing for TS is potentially useful in several settings:
  1. It can be helpful in confirming a clinical diagnosis of TS, especially in young patients in whom many clinical signs and symptoms have yet to develop.
  2. In many families with a history of TS in which there is a sporadic case of TS in a new child, genetic testing can provide reassurance to parents, children, and other family members that they do not carry the TS gene mutation.
  3. DNA testing is useful for prenatal diagnosis.

Rx TREATMENT

The management of TSC is presently symptomatic.

NONPHARMACOLOGIC THERAPY

Genetic counseling should be offered to families with affected members even though accurate counseling remains difficult because of the variability of gene expression.

ACUTE GENERAL Rx & CHRONIC Rx

- Treatment methods currently available for patients with disfiguring facial angiofibromas include cryosurgery, curettage, dermabrasion, chemical peeling, excision, and laser therapy.
- Some patients have been treated successfully with antiepileptic medications; unfortunately, there are multiple cases of intractable seizure in which medical treatment is ineffective. In some cases of intractable epilepsy, neurosurgical intervention becomes a lifesaving option.
- In such drug-resistant cases of TS, the early administration of vigabatrin (γ-vinyl-gamma aminobutyric acid), a selective irreversible inhibitor of GABA-transaminase, has been proved to result in 80% to 100% cessation rates of infantile spasms. Vigabatrin is marketed in many European countries but remains unavailable in the U.S. and has not been approved by the FDA.
- Embolization and/or renal sparing surgery are treatment options for renal angiomyolipomas.
- Oophorectomy, medroxyprogesterone, and tamoxifen have been advocated for patients with LAM, but the therapeutic benefit is unclear. Lung transplantation is reserved for patients with end-stage LAM.
- Most rhabdomyomas tend to regress with increasing age, although tumor growth has been documented in some at puberty. Surgery is recommended only for life-threatening situations, such as hemodynamic compromise.
- Oral rapamycin or sirolimus therapy can induce regression of brain astrocytomas associated with TS. Ongoing therapeutic trials with rapamycin in lymphangioleiomyomatosis appear promising.
- Neurosurgical resection is the standard treatment for subependymal giant cell astrocytomas in patients with the TSC. Trials with everolimus, which inhibits the mammalian target of rapamycin, a protein regulated by gene products involved in the TSC, have shown marked reduction in volume of subependymal giant cell astrocytomas and seizure frequency.

REFERRAL

A multidisciplinary team, including genetics, neurology, ophthalmology, nephrology, dermatology, neurosurgery, and plastic surgery, should evaluate children suspected of having TS.

! PEARLS & CONSIDERATIONS

PREVENTION

It is speculated that if one could establish the prenatal diagnosis of TS and have the patient begin using rapamycin early, one might prevent the development of TS manifestations.

Tuberous Sclerosis (Patient Information)

AUTHOR: **Ruby K. Satpathy, MD**

FIG. E4 Multiple facial angiofibromas in a patient with tuberous sclerosis. (From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

TABLE E2 Cutaneous Manifestations Associated with Tuberous Sclerosis Complex

Cutaneous Lesions	Descriptions	Age of Onset	Prevalence (%)	Diagnostic Classification
Hypomelanotic macules ("ash leaf" spots) or Fitzpatrick patches	Leaf-shaped or polygonal white spots enhanced by Wood lamp examination	Earliest cutaneous lesion; usually present on buttocks at birth or in infancy	97.2	Major
Facial angiofibromas	Red to pink papules with a smooth surface, symmetrically distributed over the centrofacial areas, sparing the upper lip	Second to fifth yr of life; become more prominent with age	74.5	Major
Shagreen patches	Slightly elevated patch or plaque, usually found on dorsal body surfaces, especially the lumbosacral area; its rough surface resembles an orange peel; represents a connective tissue nevus, sometimes called collagenoma	Rare during infancy; tend to increase in size and number with age	48.1	Major
Molluscum pendulum	Multiple soft pedunculated skin growths on neck; rarely in axillae or groin	More common during first decade of life; rare during infancy	22.6	Minor
Fibrous forehead plaque	Yellowish-brown or skin-colored plaques of variable size and shape, usually located on the forehead or scalp	Common at any age and can be seen at birth or in early infancy	18.9	Major
Periungual fibromas	Skin-colored or reddish nodules seen on the lateral nail groove or nail plate, or along the proximal nail folds; more commonly found on the toes than the fingers	Present at puberty or soon after; become more common with age	15.1	Major
"Confetti-like" macules	Multiple 1 mm to 2-mm white spots, symmetrically distributed over extremities	Second decade or adulthood	2.8	Minor

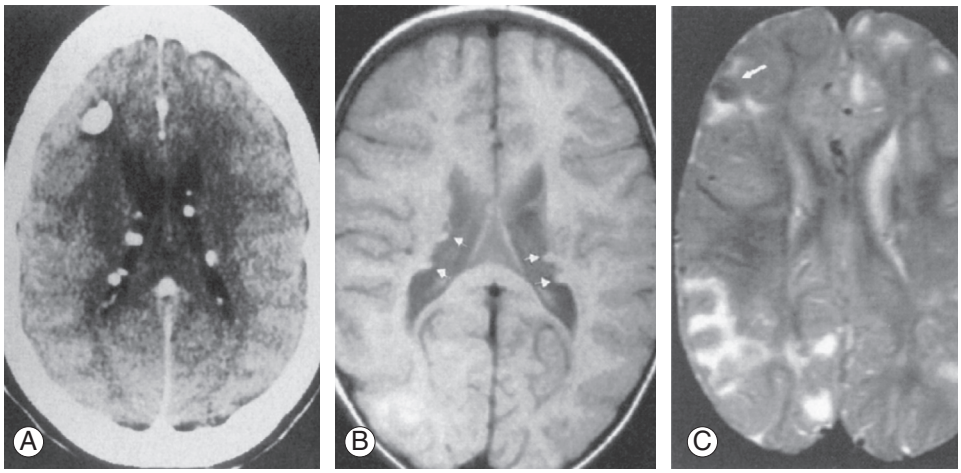

FIG. E5 Tuberous sclerosis. A, Computed tomography demonstrating periventricular calcified subependymal nodules. A cortical calcified tuber is also seen in the right frontal region. **B,** T1-weighted (WI) demonstrating the subependymal nodules *(arrows)* lining the lateral ventricles (isointense to white matter). **C,** T2WI demonstrating foci of abnormal SI throughout the subcortical white matter and in the cortex corresponding to cortical tubers. A right frontal tuber *(arrows)* is probably calcified (low SI). (From Grossman R, Yousem D: *Neuroradiology: the requisites,* 2003, Mosby. In Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

Tularemia

BASIC INFORMATION

DEFINITION

Tularemia is a zoonosis caused by the small, facultative gram-negative intracellular coccobacillus *Francisella tularensis.* Clinical manifestations range from asymptomatic illness to septic shock and death.

SYNONYMS

Rabbit fever
Deerfly fever
O'Hara disease

ICD-10CM CODES
A21.9 Tularemia, unspecified
A21.0 Ulceroglandular tularemia
A21.1 Oculoglandular tularemia
A21.2 Pulmonary tularemia
A21.3 Gastrointestinal tularemia
A21.7 Generalized tularemia
A21.8 Other forms of tularemia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Overall incidence in the U.S. had been about 120 cases/yr with the highest reported incidence found in South Dakota, Arkansas, Missouri, and Oklahoma (Fig. E1). However, in 2015 there were 314 cases in the U.S. and 230 in 2016. It is also found in Canada, Mexico, European countries, Turkey, Israel, China, and Japan.

PREDOMINANT SEX: Male
PREDOMINANT AGE: Occurs at any age but is most common in 5- to 9-yr-old children and in men >55 yr of age
PEAK INCIDENCE: June through August and in December

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical findings:

- Incubation period is 3 to 5 days but may range from 1 to 21 days
- Most common initial signs and symptoms are abrupt onset of fever and respiratory symptoms. The following signs and symptoms may also be present:
  1. Chills
  2. Headache
  3. Malaise
  4. Anorexia
  5. Fatigue
  6. Cough
  7. Myalgias
  8. Chest discomfort
  9. Vomiting
  10. Abdominal pain
  11. Diarrhea
  12. Conjunctivitis
  13. Lymphadenitis

Clinical presentation:

- Ulceroglandular and glandular: Account for 75% to 80% of cases. Fever and a single erythematous papuloulcerative lesion with a central eschar (Fig. E2) accompanied by tender lymphadenopathy. Overall mortality rate for this form of tularemia is generally low (<2%).
- Oculoglandular: Accounts for 1% to 2% of cases. Painful inflamed conjunctiva with numerous yellowish nodules and pinpoint ulcers. Purulent conjunctivitis with regional lymphadenopathy. Corneal perforation may occur.
- Oropharyngeal and gastrointestinal: Account for 1% to 4% of cases. Acute, exudative, or membranous pharyngitis associated with cervical lymphadenopathy. Ulcerative intestinal lesion associated with mesenteric lymphadenopathy, diarrhea, abdominal pain, nausea, vomiting, and GI bleeding.
- Pulmonary: Occurs often in older adults and has a higher mortality rate. Symptoms include nonproductive cough, dyspnea, or pleuritic chest pain.
- Typhoidal: 10% of all cases of tularemia, usually after ingestion of viable *F. tularensis* bacteria. Rare in the U.S. Symptoms include high continuous fever, signs of endotoxemia, abdominal pain, and severe headache. Mortality rate can approach 30%.

COMPLICATIONS

- Intravascular coagulation
- Renal failure
- Rhabdomyolysis
- Jaundice
- Hepatitis
- Meningitis
- Encephalitis
- Pericarditis
- Peritonitis
- Osteomyelitis
- Splenic rupture
- Thrombophlebitis
- Myositis and sepsis

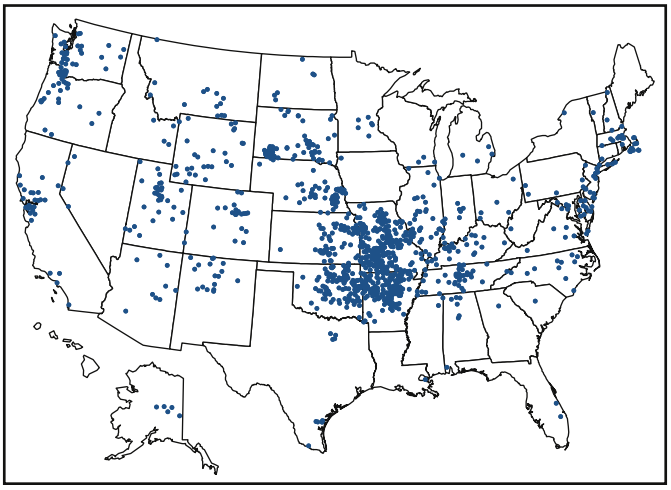

FIG. E1 Reported cases of tularemia in the United States, 2001 to 2010. One dot is placed randomly within the county of residence for each reported case. Cases were reported from 47 states. Six states accounted for 59% of reported cases: Missouri (19%), Arkansas (13%), Oklahoma (9%), Massachusetts (7%), South Dakota (5%), and Kansas (5%). (From Centers for Disease Control and Prevention [CDC]. Tularemia—United States, 2001-2010, *MMWR.* 2013;62:963-6, In Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.)

FIG. E2 Tularemia. (Courtesy of Steve Hess, MD. From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

ETIOLOGY

- Caused by infection with *F. tularensis*
- Two main biovars of *F. tularensis*: Types A and B. Type A produces severe disease in humans. Type B produces milder subclinical infection
- Transmitted by ticks, tabanid flies, and mosquitoes. Also acquired by inhalation and ingestion
- Cases also occur after exposure to animals (wild rabbit, squirrels, birds, sheep, beavers, muskrats, and domestic dogs and cats) or animal products
- Laboratory acquisition is possible
- Pathogenesis: After inoculation into the skin, the organism multiplies locally within 2 to 5 days; then it produces an erythematous tender or pruritic papule. The papule rapidly enlarges and forms an ulcer with a black base. The bacteria actively inhibit the protective host response by inducing antiinflammatory cytokines and spread to the regional lymph nodes, producing lymphadenopathy, and with bacteremia may spread to distant organs

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rickettsial infections
- Meningococcal infections
- Cat-scratch disease
- Infectious mononucleosis
- Atypical pneumonia
- Group A strep pharyngitis
- Typhoid fever
- Fungal infection—sporotrichosis
- Anthrax
- Plague
- Bacterial skin infections

WORKUP

- CBC
- Chest radiography
- Cultures of blood, lymph node, pleural fluid, wounds, sputum, and gastric aspirate
- Antigen detection in urine
- Polymerase chain reaction (PCR)
- Serology

LABORATORY TESTS

- Antibodies to *F. tularensis* demonstrated by tube agglutination, microagglutination, hemagglutination, and ELISA; definitive serologic diagnosis requires a fourfold or greater rise in titer between acute and convalescent specimens
- PCR to facilitate early diagnosis
- WBC count and ESR normal or elevated
- Rarely seen on Gram-stained smears or tissue biopsies; a tiny gram-negative bacillus

IMAGING STUDIES

Chest x-ray examination to show bilateral patchy infiltrate, lobar parenchymal infiltrate, cavitary lesion, pleural effusion, or emphysema

TREATMENT

ACUTE GENERAL Rx

- Immediate therapy to limit extent of acute illness and complications
- Streptomycin 15 mg/kg IV q12h (daily dose should not exceed 2 g) or gentamicin 5 mg/kg/day in 2 or 3 divided doses for 10 days or in the once-a-day dosing schedule
- Doxycycline 100 mg IV or PO bid
- Ciprofloxacin 400 mg IV or 750 mg PO bid for 14 to 21 days
- Combination antibiotics required for tularemic meningitis—chloramphenicol or doxycycline plus streptomycin
- Surgical therapies are limited to drainage of abscessed lymph nodes and chest tube drainage of empyemas

PROGNOSIS

The mortality rate of severe untreated infection (tularemic pneumonia and typhoidal tularemia) can be as high as 30%. The overall mortality rate associated with tularemia is 2% to 4% with appropriate treatment. Lifelong immunity usually follows tularemia.

DISPOSITION

Follow up as outpatient

PREVENTION

- Educate the public in the handling of sick or dead animals.
- Use only EPA-registered insect repellents, such as DEET or picaridin sprays.
- Remove ticks promptly.
- Drink only potable water.
- Adequately cook wild meats.
- Tularemia vaccine has been developed but is not commercially available in the U.S.; however, it is available from the CDC. Vaccination of high-risk individuals working with large quantities of cultured organism is recommended.
- Avoid skinning wild animals, especially rabbits; wear gloves while handling animal carcasses.
- Do not use wells or other water that is contaminated by dead animals.
- Hospitalized patients with tularemia do not need special isolation (no person-to-person transmission). Standard universal precautions for contaminated secretion are adequate when handling drainage from wounds.
- Laboratory personnel should be notified of potential danger of growing this organism in the laboratory and generation of an infectious aerosol from dried culture media.

REFERRAL

- For consultation with infectious diseases specialist in suspected cases.
- A cluster of tularemia cases, particularly in an urban area or nonendemic regions, should prompt concern over the possibility of bioterrorism; the local public health authorities should be contacted immediately to investigate the possibility of deliberate release of tularemia as a weapon of terror.

PEARLS & CONSIDERATIONS

- Alert the microbiology laboratory to the possibility of tularemia; this is a major biohazard in the laboratory.
- Do not use doxycycline or tetracycline in children or pregnant women.
- Because of its highly contagious nature with low inoculums, tularemia is considered an agent that could be used by terrorists. It is classified as a category A critical biologic agent by the CDC.

BASIC INFORMATION

DEFINITION

- Tumor lysis syndrome (TLS) is an oncologic emergency referring to the acute release of potentially injurious intracellular contents into the systemic circulation from tumor cell breakdown.
- TLS is a constellation of metabolic disturbances that occurs typically in the setting of rapid tumor cell lysis induced by cancer-targeted treatment (chemotherapy and/or other interventions such as embolization or radiation). However, spontaneous tumor cell turnover has induced TLS without precipitation by chemotherapy.
- TLS is characterized by hyperuricemia, hyperphosphatemia, hypocalcemia, hyperkalemia, and acute kidney injury (AKI), often with progressive oliguria.
- In the current 2004 Cairo and Bishop classification system, TLS may be defined by laboratory or clinical parameters (Table 1). Grading of clinical tumor lysis syndrome is summarized in Table 2.
  1. **Laboratory TLS** is clinically silent and defined by the presence of at least two of the following biochemical variables within 3 days before or 7 days after initiation of chemotherapy despite adequate volume status and uric acid–lowering agents.
     a. Hyperuricemia:
        (1) Results from the rapid release and catabolism of intracellular nucleic acids.
        (2) Purine nucleic acids are metabolized to hypoxanthine, xanthine, and finally, uric acid.
        (3) In an acidic environment, uric acid can precipitate in the renal tubular lumen causing obstruction.
     b. Hyperkalemia.
     c. Hyperphosphatemia: Phosphate may precipitate with calcium to form calcium phosphate stones in renal tubules.
     d. Hypocalcemia: Occurs secondary to precipitation with phosphorus.
  2. **Clinical TLS** occurs when laboratory TLS is complicated by at least one of the following clinical complications (severe renal impairment, cardiac arrhythmias, central nervous system toxicity, and/or death) that are not attributed to chemotherapy regimen.

SYNONYM

TLS

ICD-10CM CODE
E88.3 Tumor lysis syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The frequency of TLS is unknown, but it is the most common disease-related emergency encountered by physicians who treat children or adults with hematologic cancers. Incidence depends on cancer mass (greater mass correlates with greater cellular content release at cell death), patient characteristics (e.g., preexisting chronic kidney disease, volume depletion, hypotension), and supportive care. Tumor bulk, proliferation rate, and treatment sensitivity are associated with greater frequency of TLS.

PREVALENCE: Variable

PREDOMINANT SEX AND AGE:

- No sex predilection exists.
- Occurs in all age groups. Older adults are more susceptible to TLS due to a decline in glomerular filtration rate with age.

GENETICS: No racial predilection

RISK FACTORS:

- High tumor burden:
  1. Large-size tumor
  2. LDH >1500 IU/L
  3. WBC >25,000/mm^3
  4. Risk of TLS is further stratified by tumor type:
     a. High risk:
        (1) Burkitt lymphoma
        (2) High-grade non-Hodgkin lymphoma
        (3) Lymphoblastic lymphoma
        (4) Acute T-cell leukemia
        (5) Other acute leukemias
     b. Moderate risk:
        (1) Low-grade lymphoma treated with chemotherapy/radiation/corticosteroids
        (2) Multiple myeloma
        (3) Breast carcinoma treated with chemotherapy/hormonal therapy
        (4) Small-cell lung carcinoma
        (5) Germ-cell tumors (e.g., seminoma, ovarian)
     c. Low risk:
        (1) Low-grade lymphoma treated with interferon
        (2) Merkel cell carcinoma
        (3) Adenocarcinoma of the gastrointestinal tract
- Administration of certain agents, including:
  1. Paclitaxel
  2. Hydroxyurea
  3. Etoposide
  4. Fludarabine
  5. Sorafenib
- Extensive bone marrow involvement
- Elevated pretreatment uric acid, potassium, or phosphorus levels
- Tumor highly sensitive to treatment
- Volume depletion
- Chronic kidney disease
- Decreased urine output
- Acidic urine
- Tumor involvement of the kidney/renal vasculature
- Advanced age
- Post-transcatheter arterial chemoembolization (TACE), radiofrequency thermal ablation
- Chimeric antigen receptor T-cells therapy (CAR-T cell)

ETIOLOGY

Most commonly occurs in patients with acute leukemias; bulky, solid tumors; or high-grade lymphomas. The pathophysiology of tumor lysis syndrome is illustrated in Fig. E1.

- Can occur spontaneously or after antitumor intervention (chemotherapy, radiation, etc.)
- Associated with administration of certain chemotherapeutic agents (whether intravenous, intrathecal, etc.):
  1. Paclitaxel
  2. Hydroxyurea
  3. Etoposide
  4. Fludarabine
- Spontaneous TLS:
  1. Rare
  2. Lysis of tumor cells without chemotherapy or in setting of minimal chemotherapy (e.g., steroid monotherapy in case of lymphomas)
  3. Related to rapid cell turnover rate

TABLE 1 Classification of Tumor Lysis Syndrome

Laboratory tumor lysis syndrome	Two or more of the metabolic abnormalities in the next column present on the same day Occurring within 3 days before initiation of therapy or 7 days after initiation of therapy Assumes the patient receives adequate hydration and a hypouricemic agent	Uric acid ≥476 μmol/L (8 mg/dl) in adults or the upper limits of normal in children Potassium ≥6.0 mmol/L Phosphorus ≥1.5 mmol/L (4.5 mg/dl) in adults or ≥2.1 mmol/L (6.5 mg/dl) in children Calcium ≤1.75 mmol/L (7 mg/dl) or ionized calcium <1.2 mmol/L (4.5 mg/dl)
Clinical tumor lysis syndrome	Laboratory tumor lysis syndrome plus any of the criteria in the next column (not attributable to other causes)	Acute kidney injury, defined as an increase in creatinine of 26.5 μmol /L (0.3 mg/dl) or when no baseline creatinine is documented, a single value ≥1.5 times the upper limits of normal for the patient's age and sex Symptomatic hypocalcemia (e.g., tetany or paresthesias), seizure, cardiac dysrhythmia, or sudden death attributed to hypocalcemia or hyperkalemia

From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE 2 Grading of Clinical Tumor Lysis Syndrome

Stage I	Stage II	Stage III	Stage IV	Stage V
Renal failure	Serum creatinine = 1.5 UNL or creatinine clearance 30-45 ml/min	Serum creatinine = 1.5-3 UNL or creatinine clearance 20-30 ml/min	Serum creatinine = 3-6 UNL or creatinine clearance 10-20 ml/min	Serum creatinine >6 UNL or creatinine clearance <10 ml/min
Cardiac arrhythmia	Intervention not indicated	Nonurgent intervention indicated	Symptomatic and incompletely controlled or controlled with device (e.g., defibrillator)	Life-threatening (e.g., arrhythmia associated with heart failure, hypotension, syncope, shock)
Seizures	None	One brief, generalized seizure; seizure(s) well controlled by anticonvulsant, or infrequent focal motor seizures	Seizure in which consciousness is altered; poorly controlled seizure disorder, with generalized breakthrough seizures despite medical intervention	Seizure of any kind that is prolonged, repetitive, or difficult to control (e.g., status epilepticus, intractable epilepsy)

From Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.

4. Can be associated with pregnancy; fever; and rarely, generalized anesthesia in predisposed individuals
5. Hyperphosphatemia may not recur because of the reutilization of released phosphorus for resynthesis of newer tumor cells

PHYSICAL FINDINGS & CLINICAL PRESENTATION

CLINICAL PRESENTATION: Patients may present with a number of symptoms either before starting chemotherapy or commonly within 3 days after initiating cytotoxic treatment. Common symptoms include:

- Nausea
- Vomiting
- Edema
- Shortness of breath (from fluid overload or CHF)
- Lethargy or weakness
- Seizure
- Syncope
- Muscle cramp
- Tetany

PHYSICAL FINDINGS:

- Associated with specific metabolic abnormalities, including hyperkalemia, hyperphosphatemia, hyperuricemia, and hypocalcemia
- Findings often overlap for these metabolic derangements
  1. Hyperkalemia:
     a. Generalized weakness
     b. Paresthesias
     c. Paralysis
     d. ECG abnormalities:
        (1) Peaked T waves
        (2) Flattened P waves
        (3) Widened QRS complexes
        (4) Bradycardia
     e. Cardiac arrhythmias, including:
        (1) Ventricular tachycardia
        (2) Ventricular fibrillation
        (3) Asystole
        (4) Pulseless electrical activity
     f. Cardiac arrest
  2. Hyperphosphatemia:
     a. Oliguric or anuric AKI
     b. Cardiac arrhythmias
  3. Hypocalcemia:
     a. Paresthesias
     b. Tetany
     c. Neuromuscular irritability: Twitching, Chvostek sign (nonspecific), and carpopedal spasm
     d. Bronchospasm
     e. ECG abnormalities, including:
        (1) Inverted T waves
        (2) Prolonged QT interval
        (3) Ventricular arrhythmias
        (4) Heart block
     f. Cardiac arrest

ETIOLOGY

- TLS is caused by massive release of intracellular contents into the bloodstream at the time of death of neoplastic cells.
- Can occur spontaneously or after initiation of therapy in patients with:
  1. Acute leukemias
  2. Bulky solid tumors
  3. High-grade lymphomas
- Administration of certain agents:
  1. Paclitaxel
  2. Hydroxyurea
  3. Etoposide
  4. Fludarabine
- It has been reported in some cancer patients who received:
  1. Intrathecal administration of chemotherapy
  2. Rare causes: Pregnancy, fever, and rarely general anesthesia in predisposed individuals

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

See "Acute Kidney Injury" topic in Section I.

LABORATORY TESTS

- Early identification of abnormal laboratory values may prevent or reduce complications of TLS
- Laboratory TLS is defined by the presence of at least two of the following biochemical criteria within 3 days before or 7 days after initiation of chemotherapy despite adequate volume repletion or use of uric acid-lowering agents:
  1. Uric acid: >8.0 mg/dl in adults or above the upper limit of the normal range for age in children
  2. Phosphorus: >4.5 mg/dl in adults or >6.5 mg/dl in children
  3. Potassium: >6.0 mEq/L
  4. Calcium: Corrected calcium <7.0 mg/dl or ionized calcium <1.12 mg/dl
- Patients should have careful and frequent laboratory and clinic monitoring:
  1. Perform frequent ECGs or continuous cardiac monitoring for arrhythmia detection
  2. Monitor renal status closely and follow daily weights and fluid intakes and outputs
  3. Monitor BUN, creatinine, phosphorus, potassium, calcium, uric acid, and LDH in high-risk patients before and up to 72 hours after initiating therapy:
     a. If evidence of TLS develops, laboratory parameters should be checked twice daily

IMAGING STUDIES

- Consider abdominal/renal ultrasound if kidney failure present.
- Consider CT chest/abdominal/pelvis to evaluate for underlying malignancies.

Rx TREATMENT

GENERAL PRINCIPLES

- Prevention is mainstay of therapy.
- Identify high-risk patients (evaluate extent of tumor burden, kidney function, and pathologic findings) to initiate prophylactic measures in a timely fashion. Delayed treatment may lead to life-threatening complications.
- Optimal treatment involves preservation of renal function and prevention of cardiac dysrhythmias and neuromuscular irritability.
- Any metabolic derangements should be corrected before starting cancer treatment.
- Prevention for high-risk patients without TLS:
  1. Prompt, vigorous volume repletion and administration of uricosuric agent are mainstays of therapy. Box 1 summarizes treatment recommendations for tumor lysis syndrome.
     a. Volume repletion:
        (1) Prevents volume depletion and corrects electrolyte derangement.

(2) Fluid intake (whether oral or intravenous) should be maintained at 2 to 3 L/m^2 per day.
(3) Begin 24 to 48 hours before initiating cancer treatment and continue for up to 72 hours after treatment.
(4) If intravenous fluids are required, isotonic solutions are appropriate (e.g., 0.9% saline or 1 L D_5W plus 3, 50-ml ampules of 1 M $NaHCO_3$).
(5) Maintain urine output at 80–100 ml/m^2 per hour.
(6) Patients with underlying cardiac or kidney dysfunction should be monitored for volume overload and necessity for loop diuretics.
(7) Hypouricemic agents (e.g., allopurinol, rasburicase, and febuxostat). Uric acid is freely filtered at the glomerulus, and handling in the renal proximal tubule is a combination of reabsorption and secretion mediated by luminal urate/anion exchanger urate transporter 1 (URAT-1) and the basolateral organic anion transporter (OAT). When the capacity to transport luminal uric acid is overwhelmed, there is potential for uric acid to crystallize within the tubular lumen. An acidic urine pH favors this process. Uric acid crystals can cause direct tubular injury by obstruction. Furthermore, intratubular and parenchymatous uric acid precipitations causes renal injury by a granulomatous reaction and necrosis of the distal tubule epithelium through induction of chemokine-mediated inflammation from monocyte chemoattractant protein-1 (MCP-1) and macrophage migration inhibition factor (MIF). There are also crystal-independent mechanisms, which target hemodynamics: these include increased peritubular capillary pressures, increased vasoconstriction, and decreased blood flow. Uric acid also may prevent recovery from AKI in TLS, because it has been shown to inhibit proximal tubule cell proliferation. These diverse mechanisms are united in their propensity to cause AKI, as reported in Fig. 2.[1]
(8) Allopurinol:
  (a) Xanthine oxidase inhibitor, which prevents the conversion of xanthine and hypoxanthine to uric acid.
  (b) The prophylactic dose is 200 to 400 mg/m^2 daily in 1 to 3 divided doses, up to a maximum of 800 mg daily. The treatment dose is 300 to 900 mg/day.
  (c) In patients with high-grade liquid tumors, Allopurinol prophylaxis may cause xanthine nephropathy/nephrolithiasis:
    • Low serum uric acid levels and high urinary xanthine levels aid in diagnosis.
    • Consideration for reduction/cessation of allopurinol therapy should then be considered.
(9) Rasburicase:
  (a) Recombinant urate oxidase is used when uric acid levels cannot be lowered by standard measures.
  (b) Given by intravenous or intramuscular route in dosages from 50 to 100 units/kg per day for 1 to 5 days.
  (c) Should not be administered at same time as allopurinol, because allopurinol reduces uric acid levels and may reduce rasburicase efficacy.
  (d) Contraindicated in pregnancy and glucose-6-phosphate dehydrogenase deficiency due to hemolytic concerns.
  (e) Cost is a limiting factor.
(10) Febuxostat dose is 120 mg by mouth daily. It has fewer drug-drug interactions than allopurinol, and dose adjustment is not needed in patients with mild to moderate renal impairment. Cost is a limiting factor.
b. Urinary alkalinization:
  (1) Uric acid more soluble at urinary alkaline pH.
  (2) Remains controversial and has fallen out of favor.
  (3) Contraindicated with hyperphosphatemia because of risk of calcium phosphate deposition leading to stones/nephrocalcinosis.

[1]Ronco C: *Critical care nephrology,* 3rd ed, Elsevier 2019.

BOX 1 Tumor Lysis Syndrome: Treatment Recommendations

When no metabolic aberration exists:
- Allopurinol 300 mg/day, reduce to 100 mg/day after 3 days of chemotherapy

OR
- Rasburicase 0.2 mg/kg IV daily × 5 days
- Hydration: 0.45% saline 3000 ml/day
- Initiate chemotherapy within 24-48 hours of admission
- Monitor serum chemistry values every 12-24 hours

When metabolic aberration exists:
- Allopurinol or rasburicase as above; reduce dose if hyperuricemia is controlled or for renal insufficiency.
- Hydration with D_5W with 2 ampules/L of $NaCO_3$, add nonthiazide diuretics as needed.
- Urinary alkalization to keep urine pH >7.0; may discontinue when serum uric acid level is normal.
- Postpone chemotherapy until uric acid has decreased and electrolytes are stable.
- Monitor serum chemistries every 6-8 hours.
- Replace calcium with slow intravenous infusion of calcium gluconate (if symptomatic or for ECG changes).
- Treat hyperkalemia and hyperphosphatemia with exchange resins and phosphate binders, respectively.

Criteria for hemodialysis in patients unresponsive to the measures listed above:
- Serum potassium >6.0 mEq/L
- Serum uric acid >20 mg/dl
- Serum phosphorus >10 mg/dl
- Fluid overload unresponsive to diuretics

Symptomatic hypercalcemia D_5W, 5% dextrose in water; *ECG*, electrocardiogram; *$NaCO_3$*, sodium carbonate.

From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 4, Philadelphia, 2014, Elsevier. From Brudno JN et al: Toxicities of chimeric antigen receptor T cells: Recognition and management, *Blood*, May 20, 2016.

TREATMENT OF PATIENTS WITH TUMOR LYSIS SYNDROME

- Principles:
  1. Early consultations for nephrology and critical care teams
  2. Preventive measures as indicated previously
  3. Aggressive treatment of electrolyte disturbances to prevent cardiac arrhythmias and neuromuscular irritability
    a. Arrhythmias tend to be resistant to conventional therapy
    b. Arrhythmias are a leading cause of death in patients with severe TLS
  4. Treatment of kidney failure
- Management of electrolyte disturbances:
  1. Multiple, coexisting electrolyte abnormalities may make conservative management strategies difficult
    a. Systemic alkalinization may be required for concurrent hyperphosphatemia, hyperuricemia, and acidemia. Alkalinization may worsen hypocalcemia

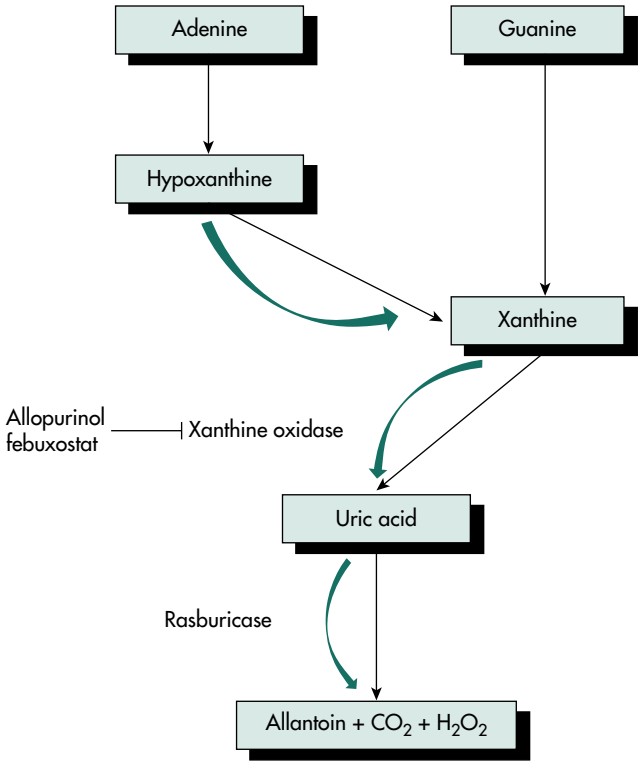

FIG. 2 Principles of therapy for the prevention and treatment of tumor lysis syndrome. (From Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.)

2. Hyperuricemia:
   a. Uric acid–lowering agents including allopurinol or rasburicase
3. Hyperkalemia:
   a. Low-potassium diet
   b. Intravenous calcium chloride/gluconate for ECG changes of hyperkalemia
   c. Intravenous infusions of glucose and insulin to shift potassium into intracellular compartments
   d. Oral potassium-exchange resins (not for acute management)
   e. Hemodialysis
4. Hyperphosphatemia:
   a. Low phosphorus diet
   b. Intravenous infusion of glucose and insulin to shift phosphorus into cells
   c. Oral phosphate binders
5. Hypocalcemia:
   a. Treat only if neuromuscular irritability is present
   b. Intravenous calcium chloride/gluconate
   c. Calcitriol can be used if the serum phosphorus level is normal, but is a relatively slow form of therapy

- Management of kidney failure:
  1. Perform standard workup for kidney failure, including urinalysis, urine microscopy, urinary electrolytes, kidney ultrasound, etc.
  2. Supportive care with intravenous fluids and diuretics (if required)
  3. Consider early dialysis if above methods fail (especially if cardiac abnormalities present)

REFERRAL

- Nephrology
- Critical care

PEARLS & CONSIDERATIONS

COMMENTS

- TLS is an oncologic emergency, which can occur spontaneously, or, more commonly, during chemotherapy-related tumor cell lysis.
- TLS is associated with the release of several intracellular contents, including potassium, phosphorus, and uric acid. With concomitant renal failure, these products are retained to pathological levels, leading to cardiac and neurological abnormalities.
- Common risk factors for TLS include highly proliferative tumors and large tumor burdens (e.g., high-grade lymphomas and acute leukemias), and preexisting metabolic derangements and renal failure.
- High-risk patients should undergo prophylactic measures initiated 24 to 48 hours before initiation of cytotoxic agents.
- Prophylactic measures include aggressive intravenous volume repletion and administration of uric acid–lowering drugs.
- Frequent laboratory testing and monitoring of vital signs, intakes and outputs, and cardiac/neurological abnormalities are recommended.
- Complications may include continued electrolyte disturbances, renal failure, uremic complications, cardiac arrhythmias, and pulmonary edema from aggressive volume repletion.

SUGGESTED READINGS

Halfdanarson TR et al: Emergencies in hematology and oncology, *Mayo Clin Proc* 92(4):609-641, 2017.

Howard SC: The tumor lysis syndrome, *N Engl J Med* 364:1844-1854, 2011.

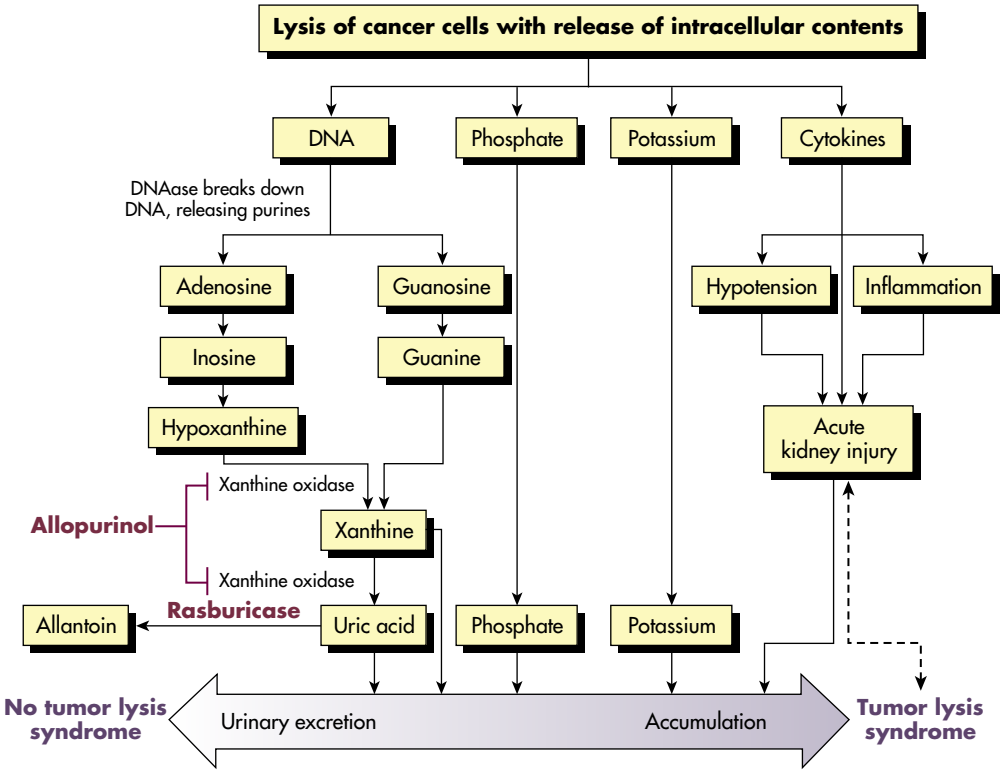

FIG. E1 Pathophysiology of tumor lysis syndrome. Lysis of cancer cells releases DNA, phosphate, potassium, and cytokines. DNA released from the lysed cells is metabolized into adenosine and guanosine, both of which are converted into xanthine. Xanthine is then oxidized by xanthine oxidase, leading to the production of uric acid, which is excreted by the kidneys. When the accumulation of phosphate, potassium, xanthine, or uric acid is more rapid than excretion, tumor lysis syndrome develops. Cytokines cause hypotension, inflammation, and acute kidney injury, which increase the risk for tumor lysis syndrome. The bidirectional dashed line between acute kidney injury and tumor lysis syndrome indicates that acute kidney injury increases the risk of tumor lysis syndrome by reducing the ability of the kidneys to excrete uric acid, xanthine, phosphate, and potassium. By the same token, development of tumor lysis syndrome can cause acute kidney injury by renal precipitation of uric acid, xanthine, and calcium phosphate crystals and by crystal-independent mechanisms. Allopurinol inhibits xanthine oxidase and prevents the conversion of hypoxanthine and xanthine into uric acid but does not remove existing uric acid. In contrast, rasburicase removes uric acid by enzymatically degrading it into allantoin, a highly soluble product that has no known adverse effects on health. (From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.)

Turner Syndrome

BASIC INFORMATION

DEFINITION

Turner syndrome is a pattern of malformation characterized by short stature, ovarian hypofunction, loose nuchal skin, and cubitus valgus, as described by Turner in 1938. An associated 45,X chromosome constitution was recognized by Ford et al in 1959.

ICD-10CM CODES

Q96.9 Turner syndrome, unspecified
Q96.8 Other variants of Turner syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

One case in every 2500 to 5000 live female births

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Turner phenotype is recognizable at any point on the developmental spectrum
- In spontaneous abortions, it is the most common sex chromosome abnormality detected (45,X chromosome constitution) and accounts for 20% of such cases
- In fetuses, it is suspected when ultrasonographic manifestations such as thickening of the nuchal folds, frank nuchal cystic hygromas, or mild shortness of the femur at midtrimester are identified
- In infants (Fig. E1):
  1. At birth may display loose nuchal skin (pterygium colli) and edema on the dorsa of hands and feet
  2. Canthal folds reflecting midface hypoplasia and redundant skin in the periorbital region
  3. Nipples appearing widely spaced (interthelial distance greater than one fourth the chest circumference)
  4. Heart and cardiovascular system: Murmur of aortic stenosis or bicuspid aortic valve or diminished femoral pulses suggestive of aortic coarctation
  5. Renal ultrasonography: Renal ectopia such as pelvic kidney or horseshoe kidneys
- In older children:
  1. Slow linear growth
  2. Short stature: May be improved with growth hormone therapy. Combining childhood ultra-low-dose estrogen with growth hormone may improve growth and provide other potential benefits associated with early initiation of estrogen replacement
  3. Delayed or absent menses: Secondary sex characteristics possibly normalized with estrogen replacement therapy
  4. Intelligence is often normal, but delays in spatial perception or visual-motor integration are commonly observed; frank mental retardation is rare

ETIOLOGY

- Abnormal phenotype caused by absence of the second sex chromosome, whether X or Y
- 45,X chromosome constitution in approximately 50% of affected individuals
- Other chromosome aberrations (40% of cases): Isochromosome Xq (46,X,i[Xq]) or mosaicism (XX/X)
- With deletions involving the short (or "p") arm of the X chromosome: Short stature but little ovarian hypofunction
- Deletions involving Xq13-q27: Ovarian failure
- Usually a deficiency of paternal contribution of sex chromosome, reflecting paternal nondisjunction

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Noonan syndrome (PTPN11 mutation), an autosomally dominant inherited disorder also characterized by loose nuchal skin, midface hypoplasia, canthal folds, and stenotic cardiac valvular defects and affecting males and females equally; also have normal chromosome constitutions
- Other conditions in the differential diagnosis of loose skin, whether or not associated with edema:
  1. Fetal hydantoin syndrome (loose nuchal skin, midface hypoplasia, distal digital hypoplasia)
  2. Disorders of chromosome constitution (trisomy 21, tetrasomy 12p mosaicism)
  3. Congenital lymphedema (Milroy edema)

WORKUP

- Giemsa banded karyotype to confirm clinical diagnosis
- Cardiologic consultation for evaluation for cardiac valvular abnormalities or aortic coarctation
- Renal ultrasonography after diagnosis is established
- Endocrine evaluations in older patients with short stature or amenorrhea
- Psychometrics to document known or suspected learning disabilities

LABORATORY TESTS

- As noted, routine Giemsa banded karyotype on peripheral lymphocytes is the gold standard to confirm the clinical impression in all suspected cases of Turner syndrome
- Important to exclude the presence of Y chromosome in mosaics
- Recognition of associated medical problems, such as hypergonadotropic hypogonadism or autoimmune thyroiditis, prompting periodic evaluation of these potential areas

IMAGING STUDIES

- Echocardiography
- Renal ultrasonography
- Abdominal ultrasonography for evaluation of ovarian and uterine size and morphology
- MRI of brain (especially in cases with known or suspected neurologic impairment)
- Radiography (for evaluation of carpal/metacarpal abnormalities, radioulnar synostosis)
- Bone age (for evaluation of short stature)

TREATMENT

Recognition of the multisystem involvement of Turner syndrome necessitates multiple medical specialists working in concert with the primary care provider to maximize and improve outcome while minimizing unnecessary or redundant testing.

NONPHARMACOLOGIC THERAPY

General medical care guided by normal medical standards with special attention paid to identifying such age-related problems as developmental delays, learning disabilities, slow growth, or amenorrhea

ACUTE GENERAL Rx

Specific treatment geared to the specific medical problem (e.g., cardiac or renal dysfunction)

CHRONIC Rx

- Estrogen-replacement therapy in early adolescents
- Some benefit from recombinant human growth hormone therapy

REFERRAL

- To geneticist: Clinical diagnosis, differential diagnosis, recurrence risk counseling, cytogenetic tests
- To endocrinologist (pediatric): Evaluation of short stature, estrogen or growth hormone replacement therapy
- To cardiologist: For cardiac valvular abnormalities or aortic coarctation

PEARLS & CONSIDERATIONS

COMMENTS

- Although newer studies are optimistic regarding outcomes, previous reports suffered from retrospective observations, case reports, and ascertainment bias, contributing to a generally poor interaction between the physician and patient.
- Affected individuals and families often benefit from the contemporary experiences and expertise of members of genetic support groups. The Turner Syndrome Society of the United States (800-365-9944; http://www.turnersyndrome.org) and the Alliance of Genetic Support Groups (800-336-4363 or 202-966-5557; http://geneticalliance.org) are valuable resources.
- A diagnosis of Turner syndrome should be considered in all girls with short stature or primary amenorrhea.
- Almost all women with Turner syndrome are infertile, although some conceive with assisted reproduction.

SUGGESTED READING

Ross JL et al: Growth hormone plus childhood low-dose estrogen in Turner's syndrome, *N Engl J Med* 364:1230-1242, 2011.

FIG. E1 Physical manifestations associated with Turner syndrome. A, This newborn shows a webbed neck with low hairline, shield chest with widespread nipples, abnormal ears, and micrognathia. **B,** The low-set posterior hairline can be better appreciated in this older child, who also has protruding ears. **C,** In this frontal view, mild webbing of the neck and small, widely spaced nipples are evident, along with a midline scar from prior cardiac surgery. The ears are low set and prominent, protruding forward. **D** and **E,** The newborn shown in **A** also has prominent lymphedema of the hands and feet. (From Madan-Khetarpal S, Arnold G: Genetic disorders and dysmorphic conditions. In Zitelli BJ [eds]: *Zitelli and Davis' atlas of pediatric physical diagnosis,* ed 6, Philadelphia, 2012, Elsevier, Fig 1.25.)

BASIC INFORMATION

DEFINITION

Typhoid fever is a systemic infection caused by *Salmonella typhi* and S*almonella paratyphi* (A, B, and C).

SYNONYMS

Typhoid
Enteric fever

ICD-10CM CODES
A01.00 Typhoid fever, unspecified
A01.02 Typhoid fever with heart involvement
A01.09 Typhoid fever with other complications

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Approximately 400 cases of *S. typhi* infections are reported annually in the U.S. (Fig. E1). Over three quarters of the cases reported in the U.S. are now associated with foreign travel (most from Asia, Africa, and Central America).

PHYSICAL FINDINGS & CLINICAL PRESENTATION (TABLE E1)

- Incubation period is 8 to 16 days
- Usual manifestations:
  1. Prolonged fever (enteric fever). Temperature increases progressively and can remain elevated daily for 4 to 8 wk
  2. Myalgias
  3. Headache
  4. Cough
  5. Sore throat
  6. Malaise
  7. Anorexia, at times with abdominal pain and hepatosplenomegaly
  8. Diarrhea or constipation may occur early in the course of illness. One fifth of patients have constipation at diagnosis
  9. Rose spots, which are faint, maculopapular, blanching lesions, may sometimes be seen on the chest or abdomen
- Relative bradycardia (despite high fever) may occur
- Moderate hepatosplenomegaly may be present
- In an untreated patient, fever may last 1 to 2 mo. The main complication of untreated disease is GI bleeding as a result of perforation from ulceration of Peyer patches in the ileum. Mental status changes and shock are rare complications. The relapse rate is approximately 10%

ETIOLOGY

- *S. typhi* or *S. paratyphi* found only in humans
- Acquisition of disease by ingestion of food or water contaminated by human feces
- In the U.S., most cases are acquired either during foreign travel or by ingestion of food prepared by chronic carriers, many of whom acquired the organism outside of the U.S., most common in the Indian subcontinent (South, East, and Southeast Asia) and portions of sub-Saharan Africa

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Malaria
- Tuberculosis
- Brucellosis
- Amebic liver abscess
- Table E2 summarizes differential diagnoses of infectious diseases to consider in patients with possible typhoid or enteric fever

WORKUP

- Diagnosis is made by isolating *Salmonella typhi* from blood, stool, urine, or bone marrow.
- Blood, stool, and urine cultures are helpful.
- Cultures should be repeated if results are initially negative.
- Blood cultures are more likely to be positive early in the course of illness.
- Stool and urine cultures are more commonly positive in the second and third week of illness.
- Bone marrow biopsy cultures are 90% positive, although this procedure is usually not necessary.
- Rapid serologic tests can distinguish *Salmonella enterica* serotype *typhi* antibodies.

LABORATORY TESTS

- Neutropenia is common. Anemia and thrombocytopenia may be present
- Transaminitis is possible
- Culture:
  1. Blood
  2. Body fluids
  3. Biopsy specimens

DIAGNOSTIC IMAGING

- Chest x-ray may reveal pulmonary infiltrates.

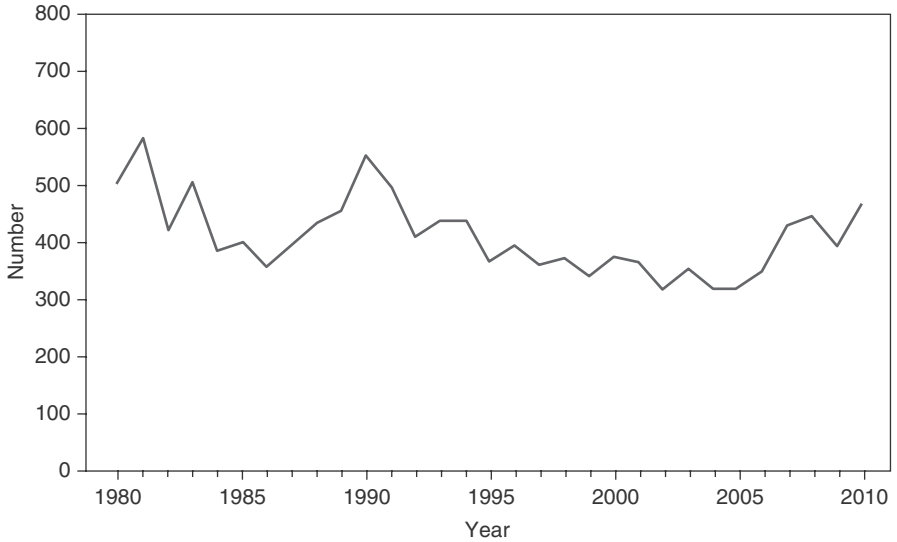

FIG. E1 Typhoid fever. Number of reported cases by yr, U.S., 1980 to 2010. (From Centers for Disease Control and Prevention: Summary of notifiable diseases—United States, 2010, *MMWR Morb Mortal Wkly Rep* 59[53]:1-111, 2012.)

TREATMENT

ACUTE GENERAL Rx

- Multidrug-resistant strains (MDR) are now common worldwide with resistance to ampicillin, Bactrim, and chloramphenicol. Resistance to quinolones is increasing, especially in Southeast Asia
- If not acquired in Asia: Ciprofloxacin 400 mg PO/IV q12h or levofloxacin 750 mg PO/IV q24h for 7 to 10 days
- If acquired in Asia: Ceftriaxone 2 g IV daily for 7 to 14 days
- An alternative agent for treatment remains azithromycin: Adults: 1 g PO on day 1, then 500 mg PO daily for 5 to 7 days. Children: 20 mg/kg orally on day 1, then 10 to 20 mg/kg (maximum 100 mg per day) for 5 to 7 days
- Dexamethasone, 3 mg/kg IV initially, followed by 1 mg/kg IV q6h for 8 doses for patients with septic shock or typhoid meningitis with antibiotic therapy
- Table E3 summarizes antibiotics commonly used in treating patients with enteric fever
- In vitro susceptibility testing should be done due to increasing antibiotic resistance

CHRONIC Rx

- Carrier states possible
- More common in age >60 yr and in people with gallstones
- Usual site of colonization: Gallbladder
- Treatment in those with persistently positive stool cultures and in food handlers
- Suggested regimens for eradication of carrier state:
  1. Ciprofloxacin 500 mg PO bid for 4 wk
  2. SMX/TMP 1 to 2 tabs PO bid for 6 wk (if susceptible)
  3. Amoxicillin, 2 g PO q8h for 6 wk (if susceptible)
- Cholecystectomy possibly required in carriers with gallstones who fail medical therapy

TABLE E1 Clinical Features of Typhoid and Paratyphoid Fever

	Clinical Feature	Approximate Frequency (%)*
Flulike symptoms	Fever	>95
	Headache	80
	Chills	40
	Cough	30
	Myalgia	20
	Arthralgia	<5
Abdominal symptoms	Anorexia	50
	Abdominal pain	30
	Diarrhea	20
	Constipation	20
Physical findings	Coated tongue	50
	Hepatomegaly	10
	Splenomegaly	10
	Abdominal tenderness	5
	Rash	<5
	Generalized adenopathy	<5

*The proportion of patients demonstrating these clinical features of enteric fever varies depending on the time, region, and type of clinical population (hospitalized or ambulatory) assessed. Estimates are drawn from recent case series in an endemic area, with patients presenting for ambulatory or inpatient care.

From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

TABLE E2 Differential Diagnoses of Infectious Diseases to Consider in Patients with Possible Typhoid or Enteric Fever

Common Infectious Causes of Nonspecific Acute Febrile Illness in Resource-limited Areas

- *Salmonella* bacteremia (typhoidal and nontyphoidal serotypes)
- Malaria
- Dengue and other arboviral fevers
- Leptospirosis
- Influenza
- Rickettsioses
- Bartonelloses

Infectious Causes of Typhoidal Illnesses, Including Prolonged Nonlocalizing Febrile Illnesses

- Persistent nontyphoidal bacteremia or abscess formation
- Typhus (rickettsiosis)
- Brucellosis
- Typhoidal tularemia
- Q fever
- Bartonellosis (including trench fever)
- Melioidosis
- Rat-bite fever, Haverhill fever *(Streptobacillus moniliformis)*
- Relapsing fever (borreliosis)
- Infective endocarditis
- Malaria
- Babesiosis
- Visceral leishmaniasis
- West African trypanosomiasis
- Tuberculosis
- Endemic mycoses (histoplasmosis)

From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

DISPOSITION

- Treated patients usually respond to therapy, with a small percentage becoming chronic carriers.
- The relapse rate is approximately 10%.
- Untreated patients may have serious complications.
- Complications of typhoid and paratyphoid fever are summarized in Table E4.

REFERRAL

- Failure of therapy
- Chronic carrier

PEARLS & CONSIDERATIONS

COMMENTS

- Live attenuated oral and IM parenteral vaccines are available for travelers to areas of high risk (Table E5).
- Oral vaccines are about 70% effective and last up to 5 yr. It is a series of four capsules taken on alternate days for persons ≥6 yr of age.
- The intramuscular vaccine is over 75% effective but lasts only 2 yr but can be given to persons ≥2 yr of age.
- Infection with antimicrobial-resistant *S. typhi* strains among U.S. patients with typhoid fever is associated with travel to the Indian subcontinent, and an increasing proportion of these infections are caused by *S. typhi* strains with decreased susceptibility to fluoroquinolones and beta-lactam antibiotics.
- Beginning in 2017 in the U.S., there has been an outbreak in 32 states of over 250 cases, including two deaths, with a strain of *Salmonella* resistant to cipro and azithromycin whose source is contaminated beef from the U.S. and soft Mexican cheese.

Typhoid Fever (Patient Information)
Salmonellosis (Related Key Topic)

AUTHOR: **Glenn G. Fort, MD, MPH**

TABLE E3 Antibiotics Commonly Used in Treating Patients with Enteric Fever

	Antibiotic	Route	Typical Pediatric Dosage*	Adult Dosage	Typical Duration	Comments
Original first-line agents	Chloramphenicol	PO/IV	12.5-25 mg/kg qid	2-3 g/day (divided qid)	14-21 days	These agents are effective for susceptible strains; however, multidrug resistance to all of these agents is common in many areas.
	Amoxicillin	PO	25-35 mg/kg tid	1 g tid	14 days	
	Ampicillin	IV	25-50 mg/kg q6h	2 g q6h	14 days	
	TMP/SMX	PO/IV	8-12 mg/kg/day (TMP) 40-60 mg/kg/day (SMX) (divided qid)	160 mg/800 mg qid	14 days	
Fluoroquinolones	Ofloxacin	PO/IV	15 mg/kg bid	400 mg PO bid	5-14 days	Ofloxacin and ciprofloxacin are effective for nalidixic acid–susceptible strains. Short courses of 5-7 days are acceptable in uncomplicated cases. Courses of 10-14 days are recommended in patients requiring hospitalization or parenteral therapy. Gatifloxacin appears effective for uncomplicated cases caused by NaR strains.
	Ciprofloxacin	PO/IV	15 mg/kg bid	500 mg PO bid	5-14 days	
	Gatifloxacin	PO	10 mg/kg qd	10 mg/kg/day qd	7 days	
Third-generation cephalosporins	Ceftriaxone	IV	50-100 mg/kg qd	1-2 g IV qd	10-14 days†	These are an alternative to fluoroquinolones for NaR strains, and for empirical therapy in areas where NaR is common.
	Cefixime	PO	10 mg/kg bid	200 mg PO bid	7-14 days	
Macrolides	Azithromycin	PO	20 mg/kg qd	500-1000 mg PO qd	7 days	These are an alternative for uncomplicated infections caused by NaR strains and for empirical therapy where multidrug resistance and NaR are common.
Eradication of carriage	Ciprofloxacin	PO	—	500-750 mg bid	28 days	If eradication is indicated for public health reasons, a trial of medical therapy is justified, even in patients with evidence of cholelithiasis. Cholecystectomy may be considered.

NaR, Nalidixic acid resistant (see text); *TMP-SMX,* trimethoprim-sulfamethoxazole.
*Weight-based pediatric dosage should not exceed adult maximum.
†Recommended that treatment continue for at least 7 days post-defervescence to minimize relapse.
From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

TABLE E4 Complications of Typhoid and Paratyphoid Fever

System	Complication	Notes
Gastrointestinal	Hemorrhage	10%-15% in hospitalized patients
	Perforation	3% in hospitalized patients
Hepatobiliary	Jaundice	1%-3% in hospitalized patients
	Hepatitis	Usually subclinical (↑ ALT/AST)
	Acute cholecystitis	Rare; gallbladder may perforate
Neurologic	Mild encephalopathy	Confusion or apathy common
	Severe encephalopathy	Delirium, stupor, or coma
	Seizures	Common in children ≤5 yr
	Meningitis	Rare, primarily infants
	Guillain-Barré syndrome	Reported
Respiratory	Bronchitis	Dry cough is common
	Pneumonia	May be other concomitant bacterial infection (e.g., *Streptococcus pneumoniae*)
	Empyema	Rare reports
Cardiovascular	Myocarditis	Usually subclinical (ECG changes)
	Endocarditis	Rare reports
Hematologic	Anemia	Usually subclinical
	Disseminated intravascular coagulation	Usually subclinical (↑ PT/PTT)
Other	Musculoskeletal pyogenic infections	Osteomyelitis (particularly vertebral), psoas abscess and others reported
	Hemolytic-uremic syndrome	Reported
	Miscarriage	Reported

ALT, Alanine aminotransferase; *AST,* aspartate aminotransferase; *ECG,* electrocardiogram; *PT,* prothrombin time; *PTT,* partial thromboplastin time.
From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

TABLE E5 Typhoid Fever Vaccines Commercially Available Internationally

Vaccine	Type	Route	Dose and Interval	Minimum Age (yr)	Protection Against *S. Typhi*	Boosting Interval in Travelers
Ty21a	Live attenuated	Oral	Four doses (in U.S.) Administer one dose every other day until complete	5*	50%-80%†	Every 5 yr
Vi capsule antigen	Polysaccharide	Intramuscular	1	2	50%-80%	Every 2 yr

*Five yr and older per World Health Organization; 6 yr and older per U.S. Advisory Committee on Immunization Practices.
†Has some efficacy against *S. paratyphi* B (see text). Additional vaccines are in development, including conjugate vaccines.
From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

BASIC INFORMATION

DEFINITION

Ulcerative colitis (UC) is an idiopathic, remitting and relapsing, chronic inflammatory bowel disease that starts in the rectum and extends proximally.

SYNONYMS

UC
Inflammatory bowel disease (IBD)
Idiopathic proctocolitis
Pancolitis

ICD-10CM CODES

K51.0	Ulcerative pancolitis
K51.2	Ulcerative proctitis
K51.3	Ulcerative rectosigmoiditis
K51.5	Left-sided colitis
K51.90	Ulcerative colitis, unspecified, without complications
K51.80	Other ulcerative colitis without complications
K51.811	Other ulcerative colitis with rectal bleeding
K51.812	Other ulcerative colitis with intestinal obstruction
K51.813	Other ulcerative colitis with fistula
K51.814	Other ulcerative colitis with abscess
K51.818	Other ulcerative colitis with other complication
K51.819	Other ulcerative colitis with unspecified complications
K51.911	Ulcerative colitis, unspecified with rectal bleeding
K51.912	Ulcerative colitis, unspecified with intestinal obstruction
K51.913	Ulcerative colitis, unspecified with fistula
K51.914	Ulcerative colitis, unspecified with abscess
K51.918	Ulcerative colitis, unspecified with other complication
K51.919	Ulcerative colitis, unspecified with unspecified complications

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence of UC is 9 to 12 cases per 100,000 persons per yr in the U.S.; worldwide, the estimated incidence ranges from 1.2 to 20.3 cases per 100,000 person-yrs and its prevalence ranges from 7.6 to 246.0 per 100,000 persons. It is most common between ages 15 and 40 yr, with a second peak between 50 and 80 yr. The disease affects men and women at similar rates. Infection with nontyphoid salmonella or campylobacter is associated with an 8-10 times higher risk of developing ulcerative colitis in the following yr. Worldwide UC is more common than Crohn disease.

PREVALENCE: The prevalence of UC is 7.6 to 246.0 cases per 100,000 per yr. Higher prevalence in Ashkenazi Jewish descendants.

GEOGRAPHIC DISTRIBUTION: The highest incidence and prevalence of IBD are seen in northern Europe and North America, and the lowest in continental Asia.

GENETICS:

- Both specific and nonspecific gene variants are associated with UC.
- There are 47 loci associated with UC, of which 19 are specific for UC and 28 are shared with Crohn disease.
- Abnormalities in humoral and cellular adaptive immunity are also found in UC.

ETIOLOGY AND PATHOGENESIS

Accumulating evidence suggests that it may result from an inappropriate inflammatory response to environmental triggers and immune dysregulation involving CD4+ T-cell Th2 response in a genetically susceptible host.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with UC often present with acute onset of bloody diarrhea accompanied by tenesmus, fever, and dehydration. At presentation 40% of adults have proctitis, 40% have left-sided colitis, and 20% have pancolitis. Diarrhea is not always present in UC patients with proctosigmoiditis and proctitis, and patients may have constipation.
- Abdominal pain is not usually a prominent symptom. Abdominal distention and tenderness may indicate the presence of complications such as toxic megacolon.
- The onset of symptoms is typically acute and is generally followed by periods of spontaneous remission and frequent relapses.
- Fever, evidence of dehydration may be present during the acute flare-up.
- Evidence of extraintestinal manifestations may be present in nearly 25% of patients: Liver disease, sclerosing cholangitis, iritis, uveitis, episcleritis, arthritis, erythema nodosum, pyoderma gangrenosum, aphthous stomatitis. Box 1 summarizes common extraintestinal manifestations of UC.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (TABLE 1, BOX 2)

- Crohn disease
- Bacterial infections:
  1. Acute: *Campylobacter, Yersinia, Salmonella, Shigella, Chlamydia, Escherichia coli, Clostridium difficile,* gonococcal proctitis
  2. Chronic: Whipple disease, tuberculosis, enterocolitis
- Irritable bowel syndrome
- Protozoal and parasitic infections (amebiasis, giardiasis, cryptosporidiosis)
- Neoplasm (intestinal lymphoma, carcinoma of colon)
- Ischemic bowel disease
- Diverticulitis
- Celiac sprue, lymphocytic or collagenous colitis, radiation enteritis, endometriosis
- Solitary rectal ulcer
- Acute self-limited colitis
- Medication (NSAIDs, chemotherapy)

WORKUP

An accurate diagnosis of UC should define the extent and severity of inflammation. Diagnostic workup includes:

- Comprehensive history, physical examination.
- Laboratory tests (see "Laboratory Tests").
- Colonoscopy to establish the presence of mucosal inflammation; typical endoscopic findings in UC are areas of continuous friable mucosa; diffuse, uniform erythema replacing the usual mucosal vascular pattern (Table 2); and pseudopolyps. The transition from abnormal to normal tissue tends to be abrupt. Rectal involvement is invariably present if the disease is active. Pathologic findings suggestive of UC include crypt abscesses and atrophy, mucin depletion, basal plasmacytosis, basal lymphoid aggregates, increased lamina propria cellularity, and Paneth cell metaplasia.

LABORATORY TESTS

- Anemia and high erythrocyte sedimentation rate (in severe colitis) are common but normal levels do not rule out the disorder.

BOX 1 Common Extraintestinal Manifestations of Ulcerative Colitis

Cutaneous/Oral
Angular stomatitis
Aphthous stomatitis
Erythema nodosum
Oral ulcerations
Psoriasis
Pyoderma gangrenosum
Pyostomatitis vegetans
Sweet syndrome (acute febrile neutrophilic dermatosis)

Ophthalmologic
Conjunctivitis
Episcleritis
Retinal vascular disease
Scleritis
Uveitis, iritis

Musculoskeletal
Ankylosing spondylitis
Osteomalacia
Osteonecrosis
Osteopenia
Osteoporosis
Peripheral arthropathy
Sacroiliitis

Hepatobiliary
Autoimmune hepatitis
Cholangiocarcinoma
Pericholangitis
PSC
Hepatic steatosis

Hematologic
Anemia of chronic disease
Autoimmune hemolytic anemia
Hypercoagulable state
Iron deficiency anemia
Leukocytosis or thrombocytosis
Leukopenia or thrombocytopenia

PSC, Primary sclerosing cholangitis.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

TABLE 1 Features That Distinguish Ulcerative Colitis from Other Diagnoses

Diagnosis	Clinical Features	Radiologic and Colonoscopic Features	Histologic Features
UC	Bloody diarrhea	Extends proximally from rectum; fine mucosal ulceration	Distortion of crypts; acute and chronic diffuse inflammatory cell infiltrate; goblet cell depletion; crypt abscesses; lymphoid aggregates
Crohn colitis	Perianal lesions are common; may be associated with ileitis; frank bleeding is less common than in UC	Segmental disease; rectal sparing; strictures, fissures, ulcers, fistulas; small bowel involvement	Focal inflammation; submucosal involvement; granulomas; goblet cell preservation; transmural inflammation; fissuring
Ischemic colitis	Occurs in older adults; sudden onset, often painful; usually resolves spontaneously in several days	Segmental splenic flexure and sigmoid involvement are most common, with thumbprinting early and ulceration after 24-72 hr; rectal involvement is rare	Mucosal necrosis with ghost cells; congestion with red blood cells; hemosiderin-laden macrophages and fibrosis (when disease is chronic)
Microscopic colitis	Watery diarrhea; normal-appearing mucosa at colonoscopy	Usually normal	Chronic inflammatory infiltrate; increased intraepithelial lymphocytes (lymphocytic colitis) and/or subepithelial collagen band (collagenous colitis)
Infectious colitis	Sudden onset; identifiable source in some cases (e.g., *Salmonella* spp.); pain may predominate (e.g., *Campylobacter* spp.); pathogens are present in stool	Nonspecific findings	Crypt architecture is usually normal; edema, superficial neutrophilic infiltrate, crypt abscesses
Amebic colitis	History of travel to endemic area; amebae may be detected in a fresh stool specimen but ELISA for amebic lectin antigen is the preferable diagnostic test	Discrete ulcers; ameboma or strictures	Similar to UC; amebae present in lamina propria or in flask-shaped ulcers, identified by periodic acid–Schiff stain
Gonococcal proctitis	Rectal pain; pus	Granular changes in rectum	Intense polymorphonuclear neutrophil infiltration; purulent exudate; Gram-negative diplococci
Pseudomembranous colitis	Often a history of antibiotic use; characteristic pseudomembranes may be seen on sigmoidoscopy; *Clostridium difficile* toxin is detectable in stools	Edematous; shaggy outline of colon; pseudomembranes may be identified radiologically or seen at colonoscopy	May resemble acute ischemic colitis; summit lesions of fibrinopurulent exudate

ELISA, Enzyme-linked immunosorbent assay; *UC,* ulcerative colitis.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

- Potassium, magnesium, calcium, and albumin may be decreased.
- Antineutrophil cytoplasmic antibodies (ANCA) with a perinuclear staining pattern (pANCA) can be found in >45% of patients; there is an increased frequency in treatment-resistant left-sided colitis, suggesting a possible association between these antibodies and a relative resistance to medical therapy in patients with UC.
- Calprotectin is a protein that is measured in feces as a marker of intestinal mucosa leukocyte activity that may be useful for screening of patients with suspected IBD. Trials have shown that based on a pretest probability of IBD of 32% in adults, an abnormal fecal calprotectin test would increase the posttest probability to 91% and a normal result would reduce the probability to 3%.
- Fecal lactoferrin is also a sensitive marker of intestinal inflammation.
- Stool examinations for ova and parasites, stool culture, and testing for *Clostridium difficile* toxin and *E. coli* O157:H7 may be useful to eliminate other causes of diarrhea in selected patients with risk factors.

IMAGING STUDIES

Image studies (plain radiography, CT scan [Fig. E1]) are generally reserved for suspected complications such as perforation of bowel or toxic megacolon.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Correct nutritional deficiencies; total parenteral nutrition with bowel rest may be necessary in severe cases. Folate supplementation may reduce the incidence of dysplasia and cancer in chronic UC.
- Avoid oral feedings during acute exacerbation to decrease colonic activity; a low-roughage diet may be helpful in early relapse.
- Psychotherapy is useful in most patients. Referral to self-help groups is also important because of the chronicity of the disease and the young age of the patients.

ACUTE GENERAL Rx

The therapeutic options vary with the degree of disease (mild, severe, fulminant) and areas of involvement (distal, extensive).

- Mild disease can be treated with 5-aminosalicylate agents (mesalamine, olsalazine, balsalazide, sulfasalazine). It can be administered as an enema (40 mg once daily at bedtime for 3 to 6 wk) or suppository (500 mg bid) for patients with distal colonic disease. Oral forms in which the 5-acetyl salicylic acid is in a slow-release or pH-dependent matrix (Pentasa 1 g qid, Asacol 800 mg PO tid) can deliver therapeutic concentrations to the more proximal small bowel or distal ileum. Olsalazine can be useful for maintenance of remission of UC in patients intolerant to sulfasalazine. Usual dose is 500 mg bid taken with food. Balsalazide is indicated for mild to moderately active UC. Usual dose is three 750-mg capsules tid. Probiotics may also be helpful in inducing remission in mild-to-moderate UC.
- Mild-to-moderate UC is often treated with a combination of rectal and oral 5-aminosalicylate. Refractory patients are candidates for oral glucocorticoids or immunosuppressive agents (e.g., cyclosporine). An algorithm for the management of mildly to moderately active UC is illustrated in Fig. 2.
- Severe disease usually responds to oral corticosteroids (e.g., prednisone 40 to 60 mg/day); the FDA has recently approved an extended-release formulation of the corticosteroid budesonide for induction of remission in mild to moderate ulcerative colitis. Corticosteroid suppositories or enemas are also useful for distal colitis. The immunosuppressant azathioprine or mercaptopurine also provides effective long-term treatment for Crohn disease. Fig. 3 describes an algorithm for the management of severely active UC.
- Biological agents are emerging treatment options for the management of ulcerative colitis. Infliximab, a chimeric monoclonal

BOX 2 Differential Diagnosis of Ulcerative Colitis

Infectious Causes
Aeromonas hydrophila
Campylobacter jejuni
Chlamydia spp.
Clostridium difficile
Cytomegalovirus
Entamoeba histolytica
Escherichia coli O157:H7, other EHEC
HSV
Listeria monocytogenes
Neisseria gonorrhoeae
Salmonella spp.
Schistosomiasis
Shigella spp.
Yersinia enterocolitica

Noninfectious Causes
Acute self-limited colitis
Behçet disease
Crohn disease
Diversion colitis
Diverticulitis
Drugs and toxins
  Chemotherapy
  Gold
  Penicillamine
Eosinophilic colitis
Graft-versus-host disease
Ischemic colitis
Microscopic colitis
  Collagenous
  Lymphocytic
Neutropenic colitis (typhlitis)
NSAIDs
Radiation colitis
SCAD
Solitary rectal ulcer syndrome

EHEC, enterohemorrhagic *Escherichia coli; HSV,* herpes simplex virus; *SCAD,* segmental colitis associated with diverticulosis.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

antibody, has been shown to be effective in patients who have not responded to corticosteroid therapy. Newer tumor necrosis factor inhibitors include adalimumab (ADA), golimumab, and vedolizumab for treatment of moderate-to-severe ulcerative colitis. These agents can be used for induction and maintenance of remission in patients that have not responded to other therapies or are corticosteroid-dependent. Head-to-head trials of these biologic agents are necessary to establish the best therapeutic option.

- Fulminant disease generally requires hospital admission and parenteral corticosteroids (e.g., IV hydrocortisone 100 mg q6h). When bowel movements have returned to normal and the patient is able to eat normally, oral prednisone is resumed. IV cyclosporine can also be used in severe refractory cases; renal toxicity is a potential complication.
- Surgery is indicated in patients who do not respond to intensive medical therapy. Fig. 4 illustrates the surgical management of chronic UC.
- Proctocolectomy is usually curative in these patients and also eliminates the high risk of developing adenocarcinoma of the colon (10% to 20% of patients develop it after 10 yr with the disease). Total proctocolectomy with ileal pouch-anal anastomosis (IPAA) is the procedure of choice for most patients who require elective surgery, since it preserves anal sphincter function. Continent ileostomy is an alternative procedure.

TABLE 2 Endoscopic Differentiation of Ulcerative Colitis and Crohn Disease

Feature	Ulcerative Colitis	Crohn Disease
Distribution	Diffuse inflammation that extends proximally from the anorectal junction	Rectal sparing, frequent skip lesions
Inflammation	Diffuse erythema, early loss of vascular markings with mucosal granularity or friability	Focal and asymmetrical, cobblestoning; granularity and friability less commonly seen
Ulceration	Small ulcers in a diffusely inflamed mucosa; deep, ragged ulcers in severe disease	Aphthoid ulcers, linear or serpiginous ulceration; intervening mucosa is often normal
Colonic lumen	Often narrowed in long-standing chronic disease; tubular colon; strictures are rare	Strictures are common

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

CHRONIC Rx

- Colonoscopic surveillance and multiple biopsies should be instituted approximately 10 yr after diagnosis because of the increased risk of colon carcinoma.
- Erythropoietin is useful in patients with anemia refractory to treatment with iron and vitamins.
- In patients on long-term steroid therapy, periodic bone density scans are recommended to screen for glucocorticoid-induced osteoporosis.

DISPOSITION

- The natural history of the disease is one of remission and episodic flares.
- The clinical course is variable. ~66% of patients will achieve clinical remission with medical therapy, and nearly 80% of treatment-compliant patients maintain remission. Fifteen percent to 20% of patients eventually require colectomy. Pouchitis is the most common long-term complication of IPAA (up to 40% of patients). >75% of patients treated medically will experience relapse.

REFERRAL

- Gastrointestinal consultation for initial diagnostic sigmoidoscopy/colonoscopy in suspected cases
- Surgical referral for patients with severe disease unresponsive to medical therapy. Indications for surgery in patients with UC are summarized in Box 3.

Unruptured Intracranial Aneurysms (UIAs)

BASIC INFORMATION

DEFINITION

Unruptured intracranial aneurysms (UIAs) are acquired aneurysms found at bifurcations of major arteries. Most are found in the circle of Willis, with 85% being at the anterior circulation. Rupture of these aneurysms results in more than 80% of nontraumatic subarachnoid hemorrhages (SAH).

SYNONYMS

Berry aneurysms
Saccular aneurysms
UIAs

ICD-10CM CODE
I67.1 Cerebral aneurysm, nonruptured

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: The incidence of UIAs is currently unknown.

PREVALENCE: The prevalence of UIAs is approximately 3% in a population without comorbidity and with a mean age of 50 yr.

PREDOMINANT SEX & AGE: UIAs are 3× more common in women and are more likely to occur in those aged 60 and older. In the pediatric population, UIAs are twice as common in males.

GENETICS: No specific genetic mutations have been shown to cause UIAs. However, more than 19 single nucleotide polymorphisms (SNP) have been associated with sporadic aneurysms. SNPs on the *EDNRA, CDKN2B,* and *SOX17* genes located on chromosomes 4, 8, and 9 have been found to have the strongest association with developing UIAs.

- Genetic disorders that increase the risk of UIAs include autosomal dominant polycystic kidney disease, Marfan syndrome, Ehlers-Danlos syndrome type IV, multiple endocrine neoplasia type I, neurofibromatosis type 1, and hereditary hemorrhagic telangiectasia. Less commonly, aneurysms can occur with systemic lupus erythematosus, fibromuscular dysplasia, sickle-cell disease, and coarctation of the aorta.

RISK FACTORS: Risk factors include female gender, older age, family history, genetic factors, cigarette smoking, and hypertension.

- Risk factors that increase the risk of subarachnoid hemorrhage are also relevant to consider, as aneurysm rupture results in subarachnoid hemorrhages. These factors include heavy alcohol use, high dose estrogen, cocaine use in young populations, and low body mass index.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

UIAs often remain asymptomatic and undetected for long periods of time but also may present with nonspecific symptoms such as headaches or vertigo. A phase of aneurysm growth usually precedes any cases of rupture. Small aneurysms (<5 mm) are likely to remain asymptomatic, while those that grow to a large size may compress surrounding structures and present with specific neurological deficits. Examples include third cranial nerve palsy due to an aneurysm of the posterior communicating or basilar arteries, hemiparesis due to middle cerebral artery aneurysms, and cavernous sinus syndrome due to aneurysms in the cavernous sinus. In rare cases, emboli may originate from aneurysms and cause transient ischemic attacks or infarctions in other regions.

ETIOLOGY

The development of aneurysms is a multifactorial process that involves hemodynamic stress, inflammation, and molecular changes that result in a weakened arterial wall. Saccular aneurysms form as protrusions that are often thin-walled and lack tunica media. Fusiform aneurysms are less common and form due to dilatation of the artery itself. It's currently thought that hemodynamic stress causes endothelial dysfunction and starts the process of arterial wall inflammation and remodeling, while other factors such as smoking and connective tissue disorders are contributory.

DIAGNOSIS

WORKUP

- The presence of UIAs should be investigated in those with a history of SAH.
- Patients with significant family history (>2 first-degree relatives with UIA or SAH), autosomal dominant polycystic kidney disease, coarctation of the aorta, or microcephalic osteodysplastic primordial dwarfism should be offered screening with MRA or CTA.

LABORATORY TEST

Lab tests are unrevealing when investigating UIAs.

IMAGING STUDIES

- Most UIAs are discovered incidentally on brain MRI or CT. However, MRA and CTA have been shown to detect smaller aneurysms and are the tests of choice in screening for UIAs. Patients with contraindications to contrast administration can be screened with MRA.
- Digital subtraction angiography is used when surgical treatment of UIA is considered.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Reduction of risk factors such as smoking.
- Exercise is associated with a reduced risk of aneurysm formation and rupture.

ACUTE GENERAL Rx

- The main surgical treatments for UIAs are endovascular coiling and surgical clipping. However, there are few guidelines for surgical treatment of UIAs. Currently, it's believed that stable UIAs at <3 mm should not undergo surgical treatment, while patients who present with headaches or nerve palsies likely should be treated surgically. Beyond this, a detailed discussion of the risks and benefits and an individualized treatment plan are necessary.
- Patients with known UIAs presenting with severe headaches or symptoms of nerve compression should raise high suspicion for development of SAH.

CHRONIC Rx

- Blood pressure management, with the goal of systolic blood pressure <140.
- Aspirin use has been associated with lower risk of aneurysm rupture.

COMPLEMENTARY & ALTERNATIVE MEDICINE

None

DISPOSITION

The risk of rupture for patients managed conservatively is related to age, smoking status, blood pressure, size and location of the aneurysm, and history of previous SAH. This risk is estimated to be 1.4% in 1 yr and 3.4% in 5 yr. Currently, it's recommended that those with family history, multiple UIAs, or a high number of risk factors should be monitored for aneurysm growth.

REFERRAL

Vascular neurology or neurosurgery

PREVENTION

Decreasing modifiable risk factors such as smoking

Upper Extremity Deep Vein Thrombosis

BASIC INFORMATION

DEFINITION

Deep vein thrombosis of the upper extremity (UEDVT) refers to the thrombosis of the subclavian, axillary, and brachial veins (Fig. E1). UEDVT has become more common due to the increased use of central venous catheters (CVCs), cardiac pacemakers, and defibrillators.

SYNONYMS

UEDVT
Upper extremity deep venous thrombosis

ICD-10CM CODES

I82.621	Acute embolism and thrombosis of deep veins of right upper extremity
I82.622	Acute embolism and thrombosis of deep veins of left upper extremity
I82.623	Acute embolism and thrombosis of deep veins of upper extremity, bilateral

EPIDEMIOLOGY & DEMOGRAPHICS

- UEDVT accounts for approximately 10% of all cases of deep vein thrombosis, resulting in an annual incidence of 0.4 to 1 case per 10,000 people.
- Complications of upper extremity deep vein thrombosis include pulmonary embolism (6%), recurrent venous thromboembolism (between 4% and 8%), and postthrombotic syndrome (15%).
- The overall 3-mo mortality rate of patients with UEDVT is 11%, which is significantly high compared to patients with lower extremity DVT.

RISK FACTORS:

- Prior line infection
- Obstructed central venous catheter
- Upper extremity surgery
- Casting of the arm with immobility
- Malignancy

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients with upper extremity deep vein thrombosis most commonly present with swelling, discoloration, or both, and pain and tenderness to palpation of the affected upper limb. Most thrombotic episodes secondary to indwelling CVCs remain subclinical and are only discovered during workup of catheter sepsis, catheter malfunction, or pulmonary embolism.

ETIOLOGY

- Primary UEDVT is a rare disorder (2 per 100,000 persons per yr) and includes idiopathic thrombosis and thrombosis associated with the thoracic outlet syndrome (TOS) or effort (Paget-Schroetter syndrome). TOS refers to compression of the neurovascular bundle as it exits the thoracic inlet. Effort thrombosis is frequently associated with TOS and occurs in young and physically active individuals.
- In contrast, individuals with idiopathic UEDVT have no known cause or underlying disease; however, it may be associated with an occult cancer.
- Secondary UEDVT represents the majority of cases and occurs in patients with CVCs, pacemakers, or cancer.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The differential diagnosis includes superficial thrombophlebitis, cellulitis, venous congestion due to external vein compression, and lymphedema.

WORKUP

Clinical signs and symptoms are often nonspecific or unreliable. A venogram, once the gold standard, is no longer used; compression ultrasonography is now the preferred imaging exam for these patients.

LABORATORY TESTS

The D-dimer test cannot be recommended for use in screening patients with suspected upper extremity deep vein thrombosis because many of these patients have coexisting conditions that are associated with an elevated D-dimer level.

IMAGING STUDIES

Compression ultrasonography (Fig. E2), which relies on the noncompressibility of a thrombosed vein, is the preferred imaging modality for patients suspected of upper extremity deep vein thrombosis. A complete examination of the internal jugular vein, the brachial and axillary vein, as well as the subclavian vein distal to the clavicle is needed. The superficial veins, the cephalic and basilic, should also be insonated at their confluence with the deep system. A recent systemic review reported a sensitivity of 97% and a specificity of 96% for the diagnosis of UEDVT with ultrasonography.

TREATMENT

No randomized controlled trials have been performed to determine the optimal treatment and duration for patients with UEDVT.

NONPHARMACOLOGIC THERAPY

In patients with catheter-associated thrombosis of the upper extremity, routine catheter removal is not recommended. Removal is indicated when there is a nonworking catheter, infection, or a contraindication to anticoagulation therapy.

ACUTE GENERAL Rx

For acute upper extremity DVT, anticoagulation therapy should be started promptly on oral factor Xa inhibitors, rivaroxaban, or apixaban. Alternatives to these agents are unfractionated heparin or low–molecular-weight heparin, with simultaneous administration of vitamin K antagonists (warfarin). Warfarin treatment should be continued for at least 3 mo, with a goal INR of 2.0 to 3.0. The ultimate treatment duration with warfarin follows the same guidelines as treatment with an LEDVT.

Although prophylaxis is not routinely recommended, dosing 1 mg of warfarin beginning 3 days before subsequent CVC placement should be considered if patient requires a future CV.

For patients with extensive swelling, recent onset of functional impairment, and low risk for bleeding complications, catheter-directed thrombolysis should be considered. Mechanical catheter interventions (aspiration, thrombectomy, balloon angioplasty, or stenting) or surgical procedures (thrombectomy, venoplasty, venous bypass, or decompression at the venous thoracic outlet) should be considered only for patients with persistent evidence of severe DVT after anticoagulation therapy or thrombolysis,

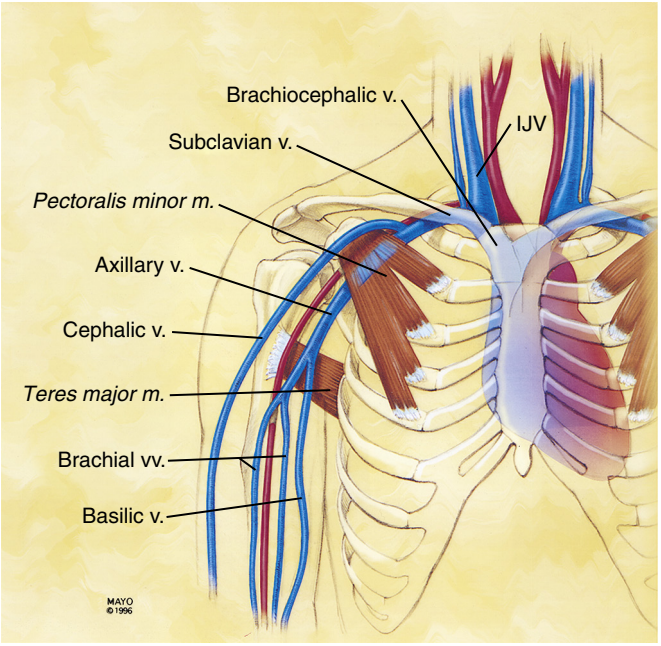

FIG. E1 Anatomy of the upper extremity veins. *IJV,* Internal jugular vein. (From Rumack CM et al: *Diagnostic ultrasound,* ed 4, Philadelphia, 2011, Elsevier.)

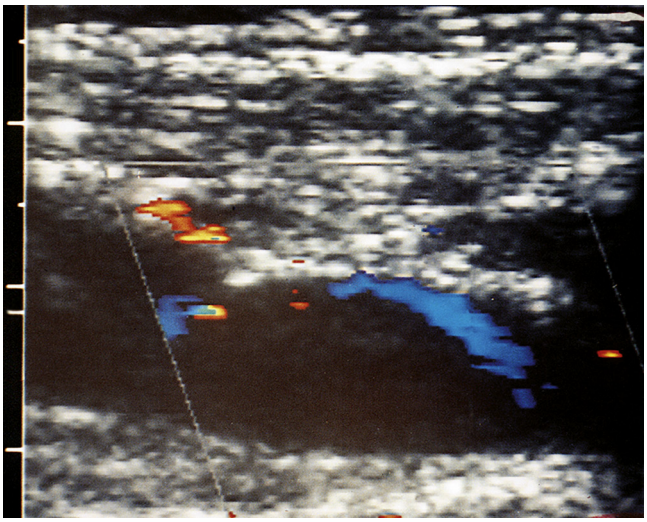

FIG. E2 Acute subclavian vein thrombosis. Color flow Doppler sonography of the subclavian vein shows extensive hypoechoic thrombus with minimal peripheral flow remaining. (From Rumack CM et al: *Diagnostic ultrasound,* ed 4, Philadelphia, 2011, Elsevier.)

and only in settings with sufficient expertise and resources.

PEARLS & CONSIDERATIONS

- Diagnosing UEDVT rapidly and accurately is essential to preventing thrombotic related morbidity and mortality.
- Catheter factors that increase the incidence of UEDVT include large luminal diameter, multiple ports, incorrect positioning, bacteremia, and prior line infection.
- The use of compression arm sleeves is recommended only in patients with persistent symptoms or in the postthrombotic syndrome.

SUGGESTED READING

Kucher N: Clinical practice. Deep vein thrombosis of the upper extremities, *N Engl J Med* 364(9):861-869, 2011.

PREVENTION

At this time, there is no convincing evidence to support routine thromboprophylaxis in all patients with central venous catheters; therefore, routine pharmacological prophylaxis is not recommended.

AUTHOR: **Frank G. Fort, MD, FACS, RPHS**

Urethritis, Gonococcal PTG ALG

BASIC INFORMATION

DEFINITION

Urethritis is a well-defined clinical syndrome manifested by dysuria, a urethral discharge, or both.

SYNONYMS

Gonococcal urethritis
GCU

ICD-10CM CODE

A54.00 Gonococcal infection of lower genitourinary tract, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Urethritis commonly is divided into two major categories based on etiology: gonococcal urethritis (GCU, *Neisseria gonorrhoeae* species) and nongonococcal urethritis (NGU, all other pathogens, most commonly *Chlamydia trachomatis*).
- This differentiation is based historically on *N. gonorrhoeae*'s easy visualization on Gram stain as gram-negative, kidney-shaped diplococci.
- In the U.S., rates of gonorrheal urethritis are rising; however, the incidence varies greatly based on race and geography; the prevalence of GCU is disproportionately higher in the South and among black, non-Hispanic men. The urethra is the most common site of infection in all men.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms of GCU: Dysuria is the most common chief complaint in patients with GCU. Additional common complaints include discharge and pruritus. Purulent discharge, meatal edema, and urethral tenderness to palpation also may occur, and 5% to 10% of patients with GCU remain asymptomatic.
- GCU may spread to other parts of the GU system. Prostatic involvement can cause urinary frequency, urgency, and nocturia and may present with mucopurulent discharge. Epididymal involvement can result in unilateral testicular pain and edema.
- Time frame: The incubation period of GCU is variable but is commonly 4 to 7 days. Without treatment, urethritis will persist for 3 to 7 wk, with 95% of men becoming asymptomatic after 3 mo.
- Complications: Periurethritis leading to urethral stenosis can occur. Additionally, disseminated infection can lead to tenosynovitis and arthritis. Rarely, hepatitis, myocarditis, endocarditis, and meningitis can occur.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- NGU
- Herpes simplex virus

LABORATORY TESTS

- If Gram staining is available, it is indicated and should be performed first, with modified Thayer-Martin media.
- Nucleic acid amplification tests (NAATs): These tests have largely replaced culture in many health care settings. They are not more sensitive than culture for detecting *N. gonorrhoeae* in cervical or urethral specimen; however, they have specificities of >99% and retain sensitivity when used to test first-catch urine or self-collected vaginal swabs. The performance of NAATs with respect to overall sensitivity, specificity, and ease of specimen transport is better than that of any of the other tests available for the diagnosis of chlamydial and gonococcal infections. NAATs should be used to detect chlamydia and gonorrhea except in cases of child sexual assault, rectal and oropharyngeal infections in prepubescent girls, and when evaluating a potential gonorrhea treatment failure in which case culture and susceptibility testing might be required.
- For culture and susceptibility testing: Rayon, Dacron, or calcium alginate tips with plastic or wire shafts should be used (not cotton-tipped swabs, which are bactericidal). A swab of the urethra should be performed within 2 to 4 hours after voiding to prevent bacterial washout with urination. Collect cultures of the pharynx and rectum when indicated for concomitant *Chlamydia* testing on all patients.
- Concomitant serologic testing for syphilis on all patients.
- Offer HIV counseling and testing to all patients.

TREATMENT

NONPHARMACOLOGIC THERAPY

Behavioral management: Avoid intercourse until cure has been attained and sexual partners have been evaluated and treated.

ACUTE GENERAL Rx

- Ceftriaxone 250 mg IM ×1 dose *plus* azithromycin 1 g orally single dose
- Dual therapy is intended for both cotreatment of potential *C. trachomatis* and to address the rising rates of gonococcal resistance to cephalosporins
- Severe allergy to cephalosporins: High-dose azithromycin with parenteral gentamicin or oral gemifloxacin

Alternative regimens:

- For penicillin-allergic patients, ceftriaxone still is recommended unless they have a history of an IgE-mediated penicillin allergy.
- Alternate regimens for those who cannot tolerate any penicillins include: Azithromycin, 2g orally plus either gentamicin 240 mg IM or gemifloxacin 320 mg orally.
- Fluoroquinolone antibiotics are no longer recommended to treat gonorrhea in the U.S. due to high rates of resistance.
- A test of cure is recommended by the CDC if any alternative regimen is administered, and should be a culture-based test collected 7 days after treatment.

CHRONIC Rx

Postgonococcal urethritis (PGU): Reinfection is the most common cause of recurrence. Repeat swab and culture of the urethra, pharynx, and rectum (where applicable) are mandatory. Persistence of polymorphonuclear cells (PMNs) with the absence of gram-negative intracellular diplococci suggests a diagnosis of PGU. This occurs when GCU is treated with a regimen that is ineffective against coincident nongonococcal infection; it represents NGU after GCU and should be treated as such. However, persistence of *N. gonorrhoeae* by smear or culture requires treatment for *N. gonorrhoeae*.

PEARLS & CONSIDERATIONS

COMMENTS

- Partner notification: The names and contact information of sexual partners should be gathered at the time of diagnosis and referred to the health department, or the patient can notify the contact directly. Expedited partner treatment is recommended by the Centers for Disease Control and Prevention (CDC) and is approved in most states. This consists of giving prescriptions to the infected patient for their partner(s) who has not been evaluated by a physician and is unlikely to seek medical care.
- On examination of the urethral smear, the presence of small numbers of PMNs provides objective evidence of urethritis. The complete absence of PMNs on a urethral smear argues against urethritis. If in addition to the PMNs there are gram-negative, intracellular diplococci, the diagnosis of gonorrhea is established.
- Patients should be advised to abstain from sex for 7 days after initiation of treatment.

Brill JR: Diagnosis and treatment of urethritis in men, *Am Fam Physician* 81(70):873-879, 2010.

Workowski KA et al: Sexually transmitted diseases treatment guidelines 2015, *MMWR Morb Mortal Wkly Rep* 64(3), 2015.

BASIC INFORMATION

DEFINITION

Nongonococcal urethritis (NGU) is urethral inflammation caused by any of several organisms (see "Etiology").

SYNONYMS

NGU
Nongonococcal urethritis

ICD-10CM CODES

A56.0 Chlamydial infection of lower genitourinary tract
N34.1 Nonspecific urethritis

EPIDEMIOLOGY & DEMOGRAPHICS

- The occurrence is 50% in sexually transmitted disease clinics. *Chlamydia trachomatis* is the most common notifiable disease in the U.S., with >1.3 million infections reported to the Centers for Disease Control and Prevention (CDC) in 2010.
- NGU most commonly affects men in a higher socioeconomic class, affecting heterosexual men more frequently than men who have sex with men.
- NGU carries a greater morbidity rate than gonococcal urethritis (GCU).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation period: 2 to 35 days.
- Symptoms: Dysuria, whitish-clear urethral discharge, and urethral itching. The onset of symptoms in NGU is less acute than GCU. The majority of persons with *C. trachomatis* infection are not aware of their infection because they do not have symptoms that would prompt them to seek medical care.
- Signs: Whitish-clear urethral discharge, meatal edema, and erythema. Infected women manifest pyuria, and the disease can present as acute urethral syndrome.

COMPLICATIONS

- Epididymitis in heterosexual men may be linked to nonbacterial prostatitis, proctitis in men who have sex with men, or Reiter syndrome.
- Urethritis complications are more common in women and can be associated with pelvic inflammatory disease or infertility.

ETIOLOGY

- Most common agent is *Chlamydia* spp., an obligate intracellular parasite possessing both DNA and RNA, which replicates by binary fission. It causes 20% to 50% of NGU cases. Two species exist:
  1. *Chlamydia psittaci*
  2. *Chlamydia trachomatis* with its 15 serotypes:
     a. Serotypes A through C cause hyperendemic-blinding trachoma.
     b. Serotypes D through K cause genital tract infection.
     c. Serotypes L1 through L3 cause lymphogranuloma venereum.
- Other causes of NGU: *Mycoplasma genitalium* (found in 44% of treatment failures with double infection with *C. trachomatis* in up to 15% of cases); *Ureaplasma urealyticum*, causing 15% to 30% of the cases of NGU; *Trichomonas vaginalis*; herpes simplex virus; and Adenovirus. The cause of 20% of the cases of NGU has not been identified.
- Asymptomatic infection occurs in 28% of the contacts of women with chlamydial cervical infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- GCU
- Herpes simplex virus
- Trichomoniasis

LABORATORY TESTS

- Requires demonstration of urethritis and exclusion of infection with *N. gonorrhoeae.*
- Nucleic acid amplification tests (NAATs): These tests have replaced culture in many settings where persons are screened for asymptomatic genital infection. The performance of NAATs with respect to overall sensitivity, specificity, and ease of specimen transport is better than that of any of the other tests available for the diagnosis of chlamydial and gonococcal infections. NAATs should be used to detect chlamydia and gonorrhea except in cases of child sexual assault involving boys, rectal and oropharyngeal infections in prepubescent girls, and when evaluating a potential gonorrhea treatment failure, in which case culture and susceptibility testing might be required.
- *Chlamydia* culture: The appearance of PMNs on urethral smear confirms the diagnosis of urethritis. Because *Chlamydia* is an intracellular parasite of the columnar epithelium, the best specimen for culture is an endourethral swab taken from an area 2 to 4 cm inside the urethra. For culture, a Dacron-tipped swab is used; avoid calcium alginate or cotton swabs. The organism can only be grown in tissue culture, which is expensive.

TREATMENT

- Because it is impossible to differentiate among the common etiologies of NGU, the condition is treated syndromically, including in the initial treatment regimen those drugs effective against the common causative agents.
- In patients with isolated uncomplicated NGU, recommended regimens are azithromycin 1 g orally single dose or doxycycline 100 mg bid × 7 days. Recommended regimen in pregnancy is azithromycin, 1 g orally as a single dose.
- In patients with confirmed urethritis and unclear etiology, concurrent treatment for gonorrhea and *Chlamydia* is recommended. In these patients, uncomplicated infections of the urethra can be treated with combination of a single 1-g dose of oral azithromycin or 100 mg doxycycline bid × 7 days *plus* ceftriaxone 250 mg × 1 dose.
- In areas where *T. vaginitis* is prevalent, men who have sex with women and have persistent or recurrent urethritis should be presumably treated with metronidazole 2 g orally in a single dose of tinidazole 2 g orally in a single dose.
- Recurrent NGU in patients initially treated with doxycycline should be treated with a single dose of azithromycin 1 g. If azithromycin was used for initial treatment, patients with recurrent NGU should be retreated with moxifloxacin 400 mg daily × 6 days.

PEARLS & CONSIDERATIONS

COMMENTS

- Partner notification: The names and contact information of all sexual partners within preceding 60 days should be gathered at the time of the visit and referred to the health department, or the patient notifies the contacts directly. Expedited partner treatment is recommended by the CDC and approved in several states. This consists of giving prescriptions to the infected patient for their partner(s) who have not been evaluated by a physician and are unlikely to seek medical care.
- Patients should abstain from intercourse for 7 days after therapy completion.

BASIC INFORMATION

DEFINITION

Urinary tract infection (UTI) is a term that encompasses a broad range of clinical entities that have in common a positive urine culture. A conventional threshold is growth of >100,000 colony-forming units per milliliter from a midstream-catch urine sample with no more than two species of organisms and at least one sign or symptom of UTI (urgency, frequency, dysuria, suprapubic tenderness, fever >38.0° C [100.4° F]). In symptomatic patients, a smaller number of bacteria (between 100 and 10,000 colony-forming units per milliliter of midstream urine) is recognized as an infection.

ICD-10CM CODES

N39.0	Urinary tract infection, site not specified
N99.521	Infection of other external stoma of urinary tract
N99.531	Infection of other stoma of urinary tract
N30.00	Acute cystitis without hematuria
N30.30	Trigonitis without hematuria
N30.20	Other chronic cystitis without hematuria

CLASSIFICATION

- Uncomplicated UTI: Occurs in a normal urinary tract and resolves rapidly with conventional antimicrobials. Patients have a low risk of upper UTI.
- Complicated UTI: Occurs in patients with coexisting pathology (strictures, stones, comorbidities [diabetes mellitus, multiple sclerosis, spinal cord injuries]). Patients are considered at high risk for upper UTI.
- First infection: The first documented UTI; tends to be uncomplicated and is easily treated.
- Unresolved bacteriuria: UTI in which the urinary tract is not sterilized during therapy. Main causes are bacterial resistance, patient noncompliance with medication, mixed bacterial infection, rapid reinfection, azotemia, infected stones, Munchausen syndrome, and papillary necrosis.
- Bacterial persistence: UTI in which the urine cultures become sterile during therapy, but a persistent source of infection gives rise to reinfection by the same organism. Causes include infected stone, chronic bacterial prostatitis, atrophic infected kidney, vesicovaginal or enterovesical fistulas, obstructive uropathy, infected pyelocaliceal diverticula, infected ureteral stump after nephrectomy, infected necrotic papillae from papillary necrosis, infected urachal cysts, infected medullary sponge kidney, urethral diverticula, and foreign bodies.
- Reinfection: UTI in which a new infection occurs with new pathogens at variable intervals after a previous infection has been eradicated.
- Relapse: The less common form of recurrent infection; occurs within 2 wk of treatment when the same organism reappears in the same site as the previous infection. Relapsing infections of the urinary tract most commonly occur in pyelonephritis, kidney obstruction from a stone, foreign body, and prostatitis.

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- UTI is the most common bacterial infection encountered in the ambulatory care setting in the U.S. The self-reported annual incidence of UTI in women is 12%, and by age 32 half of all women report having had at least one UTI.
- UTIs account for 8 million health care visits per yr and 15% of all outpatient prescriptions.
- In neonates: More common in boys as a result of anatomic abnormalities such as the posterior urethral valves.
- In preschool children: More common in girls (4.5% vs. 0.5% for boys).
- In adulthood: More common in women, with a 1% to 3% prevalence in nonpregnant women. Table 1 describes factors modulating risk for acute uncomplicated UTIs in women. In pregnancy at 12 wk, the incidence of asymptomatic bacteriuria is similar to nonpregnant women, at 2% to 10%. However, 25% to 30% of pregnant women with untreated asymptomatic bacteriuria develop acute pyelonephritis, especially in the second and third trimesters, and have a pyelonephritic recurrence rate of 10%. In adults aged ≥65 yr, at least 10% of men and 20% of women have bacteriuria.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Typical symptoms of UTI include:
  1. Urinary frequency, urgency
  2. Dysuria
  3. Suprapubic pain
  4. Gross or microscopic hematuria
- The probability of cystitis is greater than 50% in women with any symptom of UTI and greater than 90% in women who have dysuria and frequency without vaginal symptoms.
- Clinical symptoms alone can be used to make the diagnosis of uncomplicated UTI in women without a urine culture.
- When negative cultures are associated with significant pyuria, vaginal discharge, or hematuria, infections with *Chlamydia trachomatis, Neisseria gonorrhoeae*, and *Trichomonas vaginalis* should be considered.
- Acute pyelonephritis presents with fever, flank or abdominal pain, chills, malaise, and vomiting. It is these systemic symptoms that distinguish pyelonephritis from cystitis. Complications of acute pyelonephritis are renal abscess, perinephric abscess, emphysematous pyelonephritis, and pyonephrosis.

ETIOLOGY & PATHOGENESIS

- Most UTIs are caused by ascending fecal flora, which can colonize the vaginal and periurethral tissues and eventually enter the bladder.
- Other risk factors: Incomplete bladder emptying due to neurologic disease, bladder outlet obstruction or urethral stricture, renal failure, diabetes, vesicoureteral reflux, fistula, urinary diversion, infected stones, age, pregnancy, instrumentation, and poor patient compliance.
- Catheters: All patients who require a long-term Foley catheter eventually develop significant levels of bacteriuria. Treatment is reserved for individuals who become symptomatic (leukocytosis, fever, chills, malaise, loss of appetite, etc.) Using prophylactic antibiotics to treat patients who have chronic catheters is not indicated because of the risk of acquiring bacteria resistant to antibiotic therapy.
- Once bacteria reach the urinary tract, three factors determine whether symptomatic infection occurs (Box 1). These factors also determine the anatomic level of the UTI:
  1. Virulence of the microorganism
  2. Inoculum size
  3. Adequacy of the host defense mechanisms
- Urinary pathogens: In 90% of UTIs the infecting organism is gram-negative bacilli. *Escherichia coli* is the most common pathogen (85% of UTI cases). *Staphylococcus saprophyticus* causes 10% of infections, especially in young women. Other common urinary pathogens include *Klebsiella, Enterobacter, Serratia, Proteus,* and *Pseudomonas.*
- In contrast, the organisms that commonly colonize the distal urethra and skin of both men and women and the vagina of women

TABLE 1 Factors Modulating Risk for Acute Uncomplicated Urinary Tract Infections in Women

Host Determinants	Uropathogen Determinants
Behavioral: Sexual intercourse, use of spermicidal products, recent antimicrobial use, suboptimal voiding habits	*Escherichia coli* virulence determinants: P, S, Dr, and type I fimbriae; hemolysin; aerobactin; serum resistance
Genetic: Innate and adaptive immune response, enhanced epithelial cell adherence, antibacterial factors in urine and bladder mucosa, nonsecretor of ABO blood group antigens, P_1 blood group phenotype, reduced *CXCR1* expression, previous history of recurrent cystitis	
Biologic: Estrogen deficiency in postmenopausal women, micturition	

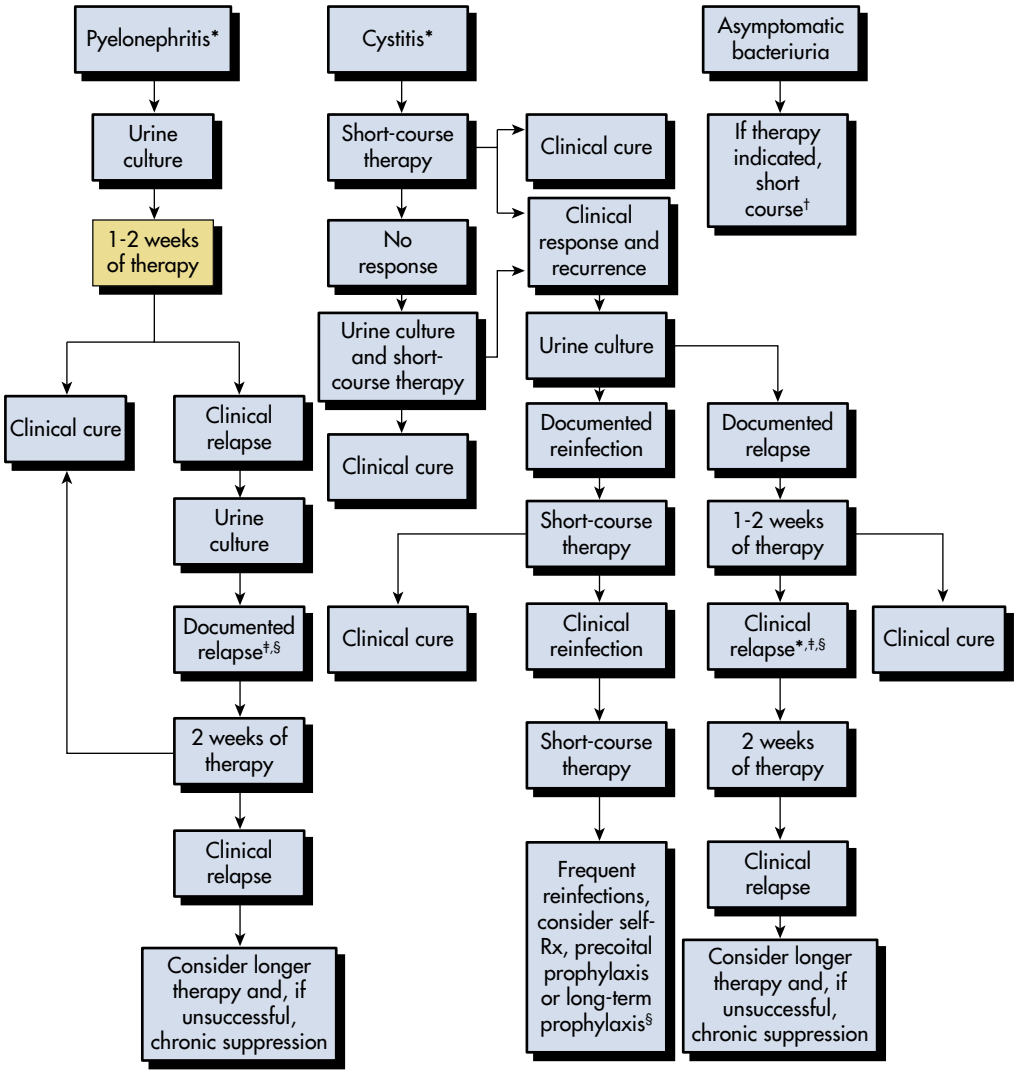
From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.

BOX 1 Bacterial Factors

- The size of the inoculum
  1. The virulence of the infecting organism
  2. Virulence factors
     a. P-fimbriae facilitate the adherence of bacteria to biologic surfaces.
     b. K-antigens facilitate adherence and protect the organisms from the host-immune response.
     c. O-antigens are an important source of systemic reactions such as fever and shock that occur with bacterial infections.
     d. H-antigens are associated with flagella and are related to bacterial locomotion.
     e. Hemolysin may potentiate tissue damage and facilitate local bacterial growth.
     f. Urease alkalinizes the urine and facilitates stone formation, thus potentiating infection.
  3. Biofilms harbor bacteria on prosthetic devices and may be a source of recurrent infections.
  4. The presence of sialosyl galactosyl globoside on the surface of kidney cells. This compound is a highly powerful receptor for *Escherichia coli* bacteria.
  5. Women with a deficiency in human beta-defensin-1 are at greater risk for urinary tract infection.
- Adequacy of host defense mechanisms

are *Staphylococcus epidermidis*, diphtheroids, lactobacilli, *Gardnerella vaginalis*, and a variety of anaerobes that rarely cause UTIs. In general, the isolation of two or more bacterial species from a urine culture signifies a contaminated specimen unless the patient is being managed with an indwelling catheter or urinary diversion or has a chronic complicated infection.

- Defense mechanisms against cystitis: Low urine pH and high urine osmolarity, mucopolysaccharide glycosaminoglycan (GAG) protective layer, normal bladder that empties completely, and low vaginal pH due to the presence of estrogen and resulting colonization of the genital tract by lactobacillus. According to Walters and Karram, Tamm-Horsfall proteins are secreted in the kidney to help inhibit adherence of bacteria to urothelial cells.



*Consider imaging studies in all men and in women with complicated urinary tract infection.
†No therapy except for renal transplant patients or prior to urologic procedures. Follow-up culture only in transplant patients.
‡Evaluate men for chronic bacterial prostatitis.
§Consider imaging studies in women.

FIG. 1 Approach to the management of urinary tract infection in nonpregnant adults. (From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.)

- In uncomplicated, nonpregnant patients, cystitis rarely progresses to pyelonephritis or other serious infections such as bacteremia.

Dx DIAGNOSIS (FIG. 1)

DIFFERENTIAL DIAGNOSIS

- Vaginitis
- Urethritis (gonococcal, nongonococcal, *Trichomonas*)
- Interstitial cystitis (painful bladder syndrome)
- Pelvic inflammatory disease
- Nephrolithiasis
- Structural urethral abnormalities such as diverticulum or stricture

LABORATORY TESTS

- Microscopic urinalysis of clean-catch urine for bacteria and pyuria. The presence of ≥10 leukocytes/μl of unspun urine from a midstream catch indicates possible UTI. The absence of pyuria should call into question the diagnosis of UTI.
- Dipstick urinalysis with the presence of nitrites or leukocyte esterase is indicative of UTI. However, dipstick urinalysis may not be useful in symptomatic patients with typical symptoms and a negative dipstick urinalysis does not exclude the diagnosis of UTI such cases; additionally, dipsticks may be falsely positive when the urine is contaminated (dipstick nitrate and leukocyte esterase have a sensitivity of 75% and specificity of 82% in patients with >100,000 CFU/ml).
- Urine culture and sensitivity are useful in complicated UTIs and to help guide therapy in women who fail initial therapy. They are generally not needed in uncomplicated UTIs.

IMAGING STUDIES

- Warranted only if renal infection or genitourinary abnormality is suspected
- CT urogram, voiding cystourethrogram, renal ultrasound, and intravenous pyelogram
- Specialty examination: Cystoscopy and retrograde pyelography to rule out obstructive uropathy, if suspected urethral diverticulum, suspected mesh, or to rule out cancer in older patients.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Urinary analgesics such as phenazopyridine and aggressive hydration

ACUTE GENERAL Rx

- First-line antimicrobials for uncomplicated UTI as recommended by the Infectious Disease Society of North America, the American Urologic Society, and ACOG include: Nitrofurantoin bid for 5 days, trimethoprim plus sulfamethoxazole (TMP-SMX) bid for 3 days, or fosfomycin 3-g sachet in a single dose.
- Antimicrobial stewardship and drug resistance needs to be considered when choosing antibiotic therapy. Empiric treatment with TMP-SMX is considered appropriate when resistance rates are below 20%. Nitrofurantoin continues to have the lowest rates of antimicrobial resistance. Beta lactam antibiotics may be appropriate in cases of known patient hypersensitivity to conventional first-line agents.
  1. Nitrofurantoin may have lower rates of bioavailability in patients >65 yr due to decline in renal function (if Cr Cl < 30 ml/min) and thus should be avoided, as it may not reach therapeutic concentration in the urine.
- High rates of resistance and the potential for serious side effects should limit the use of fluoroquinolone antimicrobials. The U.S. FDA has warned against the use of fluoroquinolone antibiotics for routine infections when suitable alternatives are available.
- Pyelonephritis may be treated as an outpatient in stable, well-hydrated patients with close follow-up. Antimicrobial selection is ideally based on urine culture results. Empiric treatment with fluoroquinolone antimicrobials or TMP-SMX is acceptable. Initiation of treatment in the emergency room setting with a single parenteral dose of a long-acting beta lactam or aminoglycoside antibiotic followed by oral treatment with fluoroquinolones or TMP-SMX is an acceptable regimen. Patients should be assessed for a proper response to treatment within 48 hr. Nitrofurantoin and fosfomycin are not indicated for the treatment of pyelonephritis due to inadequate renal tissue levels.
- Inpatient management of pyelonephritis should begin with parenteral antimicrobials followed by transition to oral agents based on clinical response and culture results.
- Pyelonephritis requires a total duration of 10 to 14 days of therapy, although evidence exists that 7 to 10 days may be equally effective in low-risk patients.See Table 2.

PEARLS & CONSIDERATIONS

COMMENTS

- Asymptomatic bacteriuria occurs commonly in postmenopausal women. Treatment of asymptomatic bacteriuria with antimicrobials is discouraged because it seldom resolves and can result in the development of drug-resistant organisms. Patients with cloudy or foul-smelling urine should be encouraged to aggressively hydrate to eliminate these symptoms. Postmenopausal women with vaginal atrophy can be treated with vaginal estrogen to reduce the incidence of bacteriuria. Exceptions include immunocompromised patients, patients with structural urinary tract abnormalities, and pregnant patients.
- Pregnancy: 25% to 30% of pregnant women with untreated asymptomatic bacteriuria develop pyelonephritis. All pregnant women should be screened for asymptomatic bacteriuria and treated. Nitrofurantoin, TMP-SMX, and beta lactam antibiotics are appropriate first-line choices in pregnancy.
- Recurrent UTI: Two or more symptomatic UTIs over a 6-mo period or three or more episodes over a 12-mo period. Causes include unresolved infection, abnormal vaginal colonization by the originally infecting organism, or reinfection with a new strain. Management of recurrent UTI includes antibiotic prophylaxis for 6 months or longer, intermittent self-treatment, and postcoital prophylaxis depending on the circumstances. Patients with recurrent UTIs can be considered for an anatomic evaluation including office cystoscopy and upper urinary tract imaging (renal ultrasound or CT urography).

TABLE 2 Dosage and Toxicity of Antibiotics Commonly Used to Treat Urinary Tract Infections

Drug	Oral Dose and Frequency	Minor Toxicity	Major Toxicity
Trimethoprim-sulfamethoxazole	160 mg/800 mg, q12h	Allergic	Serious skin reactions, blood dyscrasia
Nitrofurantoin macrocrystals	100 mg, q12h	GI upset	Peripheral neuropathy, pneumonitis
Ampicillin	250-500 mg, q6h	Allergic, candidal overgrowth	Allergic reactions, pseudomembranous colitis
Tetracycline	250-500 mg, q6h	GI upset, skin rash, candidal overgrowth	Hepatic dysfunction, nephrotoxicity
Cephalexin	250-500 mg, q6h	Allergic	Hepatic dysfunction
Ciprofloxacin	250 mg, q12h	Nausea, vomiting, diarrhea, abdominal pain, headache, skin rash	Arrhythmias, angina, convulsions, gastrointestinal bleeding, nephritis

From Walters M, Karram M: *Urogynecology and reconstructive pelvic surgery, ed 4*, Philadelphia, 2015, Elsevier.

TABLE 3 Spectrum of Antimicrobial Activity against Common Lower Urinary Tract Pathogens

Organism	Nitrofurantoin	TMP-SMX	Ciprofloxacin	Levofloxacin	Cephalexin	Ampicillin	Fosfomycin
Escherichia coli	+	±	+	+	+	±	+
Pseudomonas	–	–	+	±	–	–	+
Klebsiella	–	±	+	+	+	–	+
Proteus	±	±	+	+	±	+	±
Enterobacter	±	±	+	+	–	–	±
Enterococcus	+	–	–	±	–	+	±
Staphylococcus	+	+	±	±	±	+	+
Serratia marcescens	–	±	+	+	–	–	±

From Walters M, Karram M: *Urogynecology and reconstructive pelvic surgery, ed 4,* Philadelphia, 2015, Elsevier.

- Nonantimicrobial strategies to prevent UTI have shown mixed results. Nonantimicrobial agents with antiseptic effects on the lower urinary tract include cranberry supplements with vitamin C, d-mannose, and methenamine. Studies demonstrating clinical effectiveness of these agents show at best modest effects with few side effects. Topical estrogen has been shown to normalize the vaginal flora and may increase the thickness of the urothelium over time and should be used as an adjunct in postmenopausal women with recurrent UTI. Oral probiotics may also be beneficial by decreasing the vaginal pH.

ANTIMICROBIAL RESISTANCE:

- Because of the overuse of antibiotics, organisms once sensitive to a number of antimicrobial agents are now increasingly resistant, making effective management of UTI and pyelonephritis more difficult and potentially more dangerous. Most important has been the increasing resistance to trimethoprim plus sulfamethoxazole (TMP-SMX), the current primary care provider drug of choice for acute uncomplicated UTI in women.
- Fluoroquinolone use for the treatment of acute cystitis in women should be avoided when suitable alternatives exist. The U.S. FDA has changed the labeling of quinolone antibiotics to reflect this recommendation.
- When choosing a treatment regimen, physicians should consider such factors as:
  1. In vitro susceptibility
  2. Adverse effects on individual patients
  3. Adverse effects on the population (stewardship)
  4. Cost-effectiveness
  5. Resistance rates in their respective communities
- Meropenem (1 g IV every 8 hr) or IV plazomicin (15 mg/kg BW once daily) are effective for the treatment of complicated UTIs and acute pyelonephritis caused by Enterobacteriaceae, including multidrug-resistant strains.See Table 3.

Urolithiasis (Nephrolithiasis) PTG ALG

BASIC INFORMATION

DEFINITION

Urolithiasis is the presence of calculi within the urinary tract. The five major types of urinary stones are calcium oxalate (60% to 70%), calcium phosphate (20%), uric acid (7%), struvite (7%), and cystine (1%) (Table 1).

SYNONYMS

Kidney stones
Kidney calculi
Renal stones
Renal calculi
Ureteral stones
Ureteral calculi
Nephrolithiasis
Ureterolithiasis

ICD-10CM CODES

N20.0	Calculus of kidney
N20.1	Calculus of ureter
N20.2	Calculus of kidney with calculus of ureter
N20.9	Urinary calculus, unspecified
N21.0	Calculus in bladder
N21.1	Calculus in urethra
N21.8	Other lower urinary tract calculus
N21.9	Calculus of lower urinary tract, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Urinary stones affect approximately 1 in 11 people in the U.S., with a lifetime prevalence of approximately 10% in males and 7% in females.
- Peak incidence is in the fourth to sixth decade of life.
- Urolithiasis appears to be more common among whites than Hispanics, Asians, or African Americans.
- The incidence of urinary stone disease is increasing, likely due to increased use of cross-sectional imaging and changing dietary and lifestyle factors.
- The incidence of symptomatic urolithiasis is greatest during the summer as a result of increased temperature with resulting dehydration and urinary concentration.
- Annually, between 1 and 2 million emergency department visits are due to kidney stones and renal colic.
- Approximately 90% of all urinary stones are radiopaque. Cystine stones are faintly radiopaque. Uric acid stones are radiolucent.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Stones may be asymptomatic, or may cause the following signs and symptoms, often from urinary tract obstruction:

- Acute, often severe, flank pain (renal colic)
- Pain radiating from the flank downward and anteriorly with referred pain to the groin and genitalia (common as the stone progresses down the ureter)
- Low back and lower abdominal pain, often ipsilateral to the stone
- Nausea and vomiting
- Hematuria, gross or microscopic
- Inability to find a comfortable position
- Urinary urgency and frequency with distal ureteral stones mimicking a urinary tract infection
- Fever and chills accompanying acute colic with superimposed infection
- Elderly patients, children, and patients with neurologic deficits may present with nonspecific and vague abdominal discomfort and pain

ETIOLOGY

- Urine composition: Supersaturation of various solutes and stone constituents is the driving force in kidney stone formation. Various metabolic abnormalities such as low or high urine pH, idiopathic hypercalciuria, hypocitraturia, hyperoxaluria, and hyperuricosuria predispose patients to urinary stone formation.
- Low urine volume is the most common cause in many stone–formers.
- Dietary factors: Diets high in sodium and animal protein increase the risk of urinary stone formation. Very high dietary oxalate consumption and heavy intake of phosphoric acid-containing carbonated drinks likely increase the risk of stone formation. Foods with high potential renal acid load such as cheese and meats increase the risk of urinary stone formation, while fruits and vegetables with low potential renal acid load may reduce the risk.
- Anatomic factors predisposing patients to urinary stasis: Malrotated, horseshoe or ectopic kidney; ureteropelvic junction obstruction; vesicoureteral reflux in young children; bladder outlet obstruction; and strictures affecting the urinary tract.
- Disease states:
  1. Hyperparathyroidism with hypercalcemia and hypercalciuria
  2. Sarcoidosis with hypercalcemia
  3. Malabsorption (e.g., inflammatory bowel disease) with increased oxalate absorption
  4. Chronic diarrheal states
  5. Gastric bypass surgery with enteric hyperoxaluria
  6. Metabolic syndrome (e.g., diabetes, overweight) produces acidic urine predisposing patients to uric acid stones; it has also been suggested that metabolic syndrome increases calcium oxalate stone formation by increasing the excretion of promoters of stone formation
  7. Gouty diathesis
  8. Primary hyperoxaluria: Genetic, rare, and usually presenting as a childhood disorder
  9. Medullary sponge kidney
  10. Hyperuricosuria (e.g., metabolic defects, dietary excess) (Box 1)
  11. Type I (distal tubule) renal tubular acidosis (>1% of calcium phosphate stones)
  12. Cystinuria: Autosomal recessive disorder produces 1% of stones
- Chronic infections: Urease-producing organisms (e.g., *Proteus* [most common], *Providencia, Pseudomonas, Klebsiella, Staphylococcus*) cause alkaline urine favoring struvite or magnesium ammonium phosphate crystal formation (Box 2).
- Medications: Protease inhibitors (e.g., indinavir, ritonavir), topiramate, and chronic laxative overuse.

TABLE 1 Types of Urinary Tract Stones and Their Etiology

Composition	Etiological factors	Percentage of all stones
Calcium oxalate/calcium oxalate mixed with calcium phosphate	An underlying metabolic disorder (e.g. idiopathic hypercalciuria or hyperoxaluria) ▸ in 25% no metabolic abnormality is identified	75
Struvite or matrix calculi (composed of magnesium ammonium phosphate)	Renal infection	10-15
Uric acid	Hyperuricemia or hyperuricosuria ▸ it is idiopathic in 50%	6
Cysteine	A renal tubular defect	1-2

Other stones (e.g., xanthine stones, which may be related to a metabolic abnormality, or indinavir stones, which are drug related) are uncommon and account for <5% of all renal stones.
From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.

BOX 1 Uric Acid Stones

Low urine pH (≤5.5)
High animal protein diet
Diarrhea
Insulin resistance (high body mass index, metabolic syndrome, type 2 diabetes)

Low Urine Volume
Inadequate fluid intake
Excessive extrarenal fluid losses
Diarrhea
Insensible losses (e.g., perspiration)

Hyperuricosuria
Excessive dietary purine intake
Hyperuricemia
- Gout
- Intracellular-to-extracellular uric acid shift
- Myeloproliferative disorders
- Tumor lysis syndrome

Inborn errors of metabolism
- Lesch-Nyhan syndrome
- Glucose-6-phosphatase deficiency

From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.

BOX 2 Factors Associated with Struvite Stone Formation

- Urease-producing bacteria:
  1. *Proteus*
  2. *Klebsiella*
  3. *Providencia*
  4. *Pseudomonas*
  5. *Staphylococcus epidermidis*
  6. *Haemophilus*
  7. *Yersinia species*
  8. *Serratia*
  9. *Citrobacter*
  10. *Ureaplasma*
- Elevated urinary pH

Modified from Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.

BOX 3 Indications for a Metabolic Stone Evaluation

Recurrent stone formers
Strong family history of stones
Intestinal disease (particularly chronic diarrhea)
Pathologic skeletal fractures
Osteoporosis
History of urinary tract infection with calculi
Personal history of gout
Infirm health (unable to tolerate repeat stone episodes)
Solitary kidney
Anatomic abnormalities
Renal insufficiency
Stones composed of cystine, uric acid, struvite

From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Urinary tract infection (e.g., cystitis)
- Pyelonephritis
- Diverticulitis
- Appendicitis
- Pelvic inflammatory disease
- Ovarian pathology, including torsion
- Dysmenorrhea
- Ectopic pregnancy
- Small bowel obstruction
- Constipation
- Malignancy (primary urinary tract or retroperitoneal lymphadenopathy causing ureteral/kidney obstruction)
- Ureteropelvic junction obstruction
- Testicular torsion in children and teenagers
- Musculoskeletal back pain
- Renal infarction and renal bleeds
- Factitious (illicit substance-seeking behavior), often with recurrent stone formers

The differential diagnosis of obstructive uropathy is described in Section II.

WORKUP

- Stone composition of recovered stones should be determined by infrared spectroscopy or x-ray crystallography. Box 3 summarizes indications for a metabolic stone evaluation.
- Box 4 describes events in the medical history that may be significant with regard to urolithiasis.

LABORATORY TESTS

- Urinalysis: Hematuria is often present, but absence of hematuria does not exclude stones. Urine pH may help identify stone type: pH >7.5 is associated with struvite stones; pH <5.5 is generally associated with uric acid stones, and low serum bicarbonate concentration with urine pH ≥6 is consistent with a renal tubular acidosis.
- Urine culture and sensitivity results should be obtained selectively in patients who may have superimposed infections, based on clinical symptoms of dysuria, fever, chills or urinalysis suggestive of infection, or when surgical intervention is planned.
- Serum chemistries include electrolytes, BUN, creatinine, calcium, phosphate, uric acid and parathyroid hormone.
- Additional tests: 24-hr urine collection for volume, creatinine, calcium, uric acid, phosphate, oxalate and citrate excretion is generally reserved for patients with recurrent stones, young patients, bilateral stones and large stone burden. A 24-hr urine collection may be appropriate for motivated, first-time stone patients interested in preventing recurrent stones. An abbreviated evaluation of single-stone formers is described in Box 5. Table 2 summarizes diagnostic criteria for various disorders associated with urolithiasis.

IMAGING STUDIES

- Common diagnostic modalities for renal colic are summarized in Table 3.
- Noncontrast CT scanning ("low-dose") is rapid and accurate, has greatest sensitivity (nearly 100%) and specificity (94% to 96%), and can identify almost all stone types in essentially all locations. CT scan is the best test upon which to base stone treatment recommendations, evaluate stone persistence or passage, and plan for surgery. Indinavir antiviral therapy produces stones that are typically radiolucent and poorly visualized by noncontrast CT and usually require contrast-enhanced CT for visualization. A high index of suspicion is required for diagnosis.
- CT scans may be ordered by urologists planning surgical intervention because a CT yields information on adjacent organs and stone density that ultrasound and plain film radiography cannot reveal.
- Ultra-low-dose CT protocols specific to kidney stone evaluation are becoming more common and readily available.
- Ultrasonography or ultrasound (Fig. E1) may be an adequate initial study to detect stones or stone presence (i.e., hydronephrosis), especially in patients known to have a history of stones and in patients where radiation should be avoided (e.g., pregnancy and children). Ultrasonography is 50% to 70% sensitive in detecting stones within the kidneys, and about 90% sensitive in detecting hydronephrosis.
- Point-of-care ultrasound use is increasing in emergency departments and some clinic settings.
- Initial ultrasonography may be associated with lower cumulative radiation exposure than initial CT, without significant differences in missing, serious, or alternative diagnoses; adverse events; pain scores; return emergency department visits; or hospitalizations. It is reasonable to use ultrasonography as the initial imaging modality in suspected nephrolithiasis and to monitor known stones.
- Accuracy of sonography in detecting distal ureteral stones is variable due to variable stone size, body habitus, and operator expertise. The absence of an ipsilateral ureteral jet suggests the possibility of renal tract obstruction, but this sign is not pathognomonic.
- Abdominal radiography or a kidney-ureter-bladder x-ray (KUB) can identify radiopaque stones (e.g., calcium-containing but not radiolucent uric acid stones). However, 20% to 30% of stones will not be visible because of stone composition, poor film quality, or inadequate visualization due to overlying structures (bowel gas or bone).

Rx TREATMENT

ACUTE GENERAL Rx

- Diagnosis with labs, imaging, and patient history.
- Pain control: NSAIDs are excellent for managing renal colic (e.g., ketorolac, ibuprofen) and are preferred first-line agents. Opiates may be required for severe pain. Initial pain control with NSAIDs can reduce overall opiate dosing for renal colic. Fig. 2 illustrates a guideline algorithm for the evaluation, treatment and disposition of patients with presumed renal colic.
- IV fluids and antiemetics may be required.
- Patients with suspected urinary tract infections and obstructing stones require urgent kidney drainage (ureteral stent by a urologist or nephrostomy tube placement) and antibiotics. Patients with acute kidney injury or electrolyte derangements or those whose pain cannot be controlled also may require urgent kidney drainage.
- For patients who have a stone with a high probability of passage (i.e., small stone, especially distal ureter), medical expulsive therapy with α-blockers or calcium channel blockers (used less often due to side effects) may be helpful. New Level 1 evidence suggests that medical expulsive treatment may not be superior to placebo when considering all stone sizes; however, contemporary and numerous older studies have shown benefit to passage of distal stones ≥5 mm in size with the use of medical expulsive therapy.

BOX 4 Components of the Medical History that Are Significant for Urolithiasis

- Diseases associated with disturbances of calcium metabolism: Primary hyperparathyroidism, medullary sponge kidney, osteoporosis, immobilization, sarcoidosis, osteolytic metastases, plasmacytoma, neuroendocrine tumors, Paget disease
- Dietary history: Purine gluttony, calcium excess, milk alkali, oxalate excess, sodium excess, low citrus fruit intake
- Medications: Uricosurics, diuretics, analgesics, vitamins C and D, antacids (especially phosphorus-binding agents), acetazolamide, calcium channel blockers, triamterene, estrogens, theophylline, protease inhibitors (indinavir), sulfonamides
- Diseases associated with disturbances of oxalate metabolism: Primary hyperoxaluria types I and II, Crohn disease, ulcerative colitis, intestinal bypass surgery (especially jejunoileal bypass), ileal resection
- Diseases associated with disturbances of purine metabolism
- Intrinsic metabolic disorders: Anemia, neoplastic disorders (especially leukemias), intoxication, myocardial infarction, irradiation, cytotoxic chemotherapy
- Enzyme deficiency: Primary gout, Lesch-Nyhan syndrome
- Altered excretion: Renal insufficiency, metabolic acidosis
- Infectious history: Organisms (particularly *Proteus* and *Klebsiella*), febrile, upper tract involvement, and dates (if hospitalized)

BOX 5 Abbreviated Evaluation of Single-Stone Formers

History
  Underlying predisposing conditions (as per Box 3 and Etiology section in text)
  Medications (calcium, vitamin C, vitamin D, acetazolamide, steroids)
  Dietary excesses, inadequate fluid intake, excessive fluid loss
Multichannel blood screen
  Basic metabolic panel (sodium, potassium, chloride, carbon dioxide, blood urea nitrogen, creatinine)
  Calcium
  Intact parathyroid hormone
  Uric acid
Urine
  Urinalysis
    pH >7.5: Infection lithiasis
    pH <5.5: Uric acid lithiasis
    Sediment for crystalluria
  Urine culture
    Urea-splitting organisms: Suggestive of infection lithiasis
  Qualitative cystine
Radiography
  Radiopaque stones: Calcium oxalate, calcium phosphate, magnesium ammonium phosphate (struvite), cystine.
  Radiolucent stones: Uric acid, xanthine, triamterene
  CT scan, renal ultrasound or intravenous pyelogram: Radiolucent stones, anatomic abnormalities
Stone analysis

CT, Computed tomography.

TABLE 3 Common Diagnostic Imaging Modalities for Renal Colic

Modality	Information Provided	Radiation Dose	Contrast	Approximate Cost	Time
CT	Renal and ureteral stones, stone size, location, number, evidence of obstruction Alternative diagnoses, such as AAA, appendicitis, and free air	4-10 mSv	No	$750-$1000	Less than 5 min to perform, 30 min for interpretation
CT with IV contrast	Same as noncontrast CT Delineation of renal masses Additional information about vascular dissections and mesenteric ischemia	4-10 mSv	Yes	$750-$1000	Less than 5 min, after delay to measure creatinine
CT with IV and oral contrast	Same as CT with IV contrast Potentially improved diagnosis of bowel abnormalities	4-10 mSv	Yes	$750-$1000	Less than 5 min, after delay of approximately 2 hr to ingest oral contrast
Intravenous urogram	Structural and functional information about obstruction Rarely, identification of other pathology, such as AAA	1.5 mSv	Yes	$350	Approximately 75 min
X-ray	Possible identification of stone, but cannot assess for hydronephrosis or most other pathology	0.5-1 mSv	No	$250	Less than 5 min
Ultrasound	Identification of hydronephrosis or hydroureter Possible identification of stone Used to assess for AAA or biliary disease	No	No	$150	Approximately 15-30 min—bedside ultrasound is quicker

AAA, Abdominal aortic aneurysm; *CT*, computed tomography; *IV*, intravenous.

PREVENTION

- Increase low-calorie fluid intake. Generally, patients at increased risk for stones should increase fluid intake to maintain a urine volume of 2 to 3 L/day.
- Recommended daily allowance of dietary calcium: 800 to 1200 mg/day. Lower calcium consumption results in less gut oxalate-binding and greater colonic oxalate absorption, which in turn increases urinary oxalate and risk for calcium-based stones.
- Limiting animal protein to one serving daily is often recommended.
- Greater fruit and vegetable intake increases urinary excretion of citrate (stone inhibitor).
- Dietary sodium restriction is recommended to <2 grams daily to decrease renal calcium excretion.
- Dietary oxalate restriction in patients with hyperoxaluria may be beneficial. However, low oxalate diets can be difficult to comply with and restrict many foods that promote and maintain cardiovascular health. Box 6 describes foods containing high levels of oxalate.
- Increased dietary citrate (e.g., lemons, limes, oranges).
- Stone specific therapy (Fig. 3):
  1. Uric acid calculi can be prevented or even dissolved at urine pH levels greater than 6 to 6.5. This often is accomplished with potassium citrate or sodium bicarbonate taken 2 or 3 times daily with food. Correction of metabolic syndrome, obesity and diabetes is also preventative for uric acid stones.
  2. Calcium stones:
     a. In general, cannot be dissolved and either persist, pass or are removed.
     b. With hypercalciuria, thiazide diuretics and low-sodium diet are appropriate. Potassium citrate supplementation for patients with calcium stones and low 24-hr urine citrate excretion. Potassium citrate may also be effective with calcium stones even when urine citrate excretion is not low. Potassium citrate can treat the hypokalemia induced by thiazide diuretics.
     c. Urate-lowering treatment for patients with hyperuricosuria but not hypercalciuria.
  3. Struvite stones:
     a. Treating and preventing urinary tract infections reduces struvite stone formation and recurrence.
     b. Difficult to efficiently dissolve and rarely done due to treatment side effects and logistics.
     c. Urease inhibitor treatment by acetohydroxamic acid is considered for poor surgical candidates or those unable to fully clear stones. This agent is poorly tolerated and infrequently used in contemporary practice.
     d. Surgical interventions usually are required to remove struvite stones. Percutaneous nephrolithotomy (PCNL) and/or ureteroscopy are usually needed to adequately treat struvite stones as they facilitate active stone removal. Shock wave lithotripsy (SWL) can be used, but this does not actively remove the stones and may potentiate further UTIs.
  4. Cystine stones:
     a. High fluid intake of 3 to 4 L daily is the principal therapy, although it is hard to accomplish.
     b. Alkalinize urine to pH >6.5 to 7, often with potassium citrate.
     c. Thiol drugs such as D-penicillamine and tiopronin reduce the poorly soluble cystine to a soluble cysteine–drug complex. Tiopronin is better tolerated than penicillamine, but long-term compliance with both is infrequent.
- Surgical therapy
  1. Surgical treatment is needed for patients with severe pain unresponsive to medication, possible infection from an obstructing stone, acute kidney injury from ureteral obstruction, refractory nausea/vomiting and prolonged kidney obstruction (i.e., risk of irreversible renal damage).
  2. Ureteral stones can often be managed with ureteroscopy or SWL.
  3. Stones in the kidney can be managed with ureteroscopy or SWL if <1 to 2 cm in diameter and in a favorable location. As a stone becomes larger and more complex, PCNL becomes the preferred means of management.
  4. Indications for PCNL are described in Table 4.
- Guidelines for ureteral stone treatment:
  1. Proximal ureteral stones <1 cm diameter: SWL or ureteroscopy preferred.
  2. Proximal ureteral stones >1 cm diameter: SWL, ureteroscopy or PCNL for complex and/or large stones.
  3. Distal ureteral stones <1 cm diameter: Ureteroscopy or SWL, although ureteroscopy is generally preferred.
  4. Distal ureteral stones >1 cm diameter: Ureteroscopy or SWL; ureteroscopy is generally preferred.

CHRONIC Rx

Maintenance of proper hydration and dietary restrictions (see "Acute General Rx")

DISPOSITION

- More than 50% to 80% of patients will pass a ureteral stone within 4 to 6 weeks of presentation. Remember the "10 minus size of the stone in mm × 100% rule." For example,

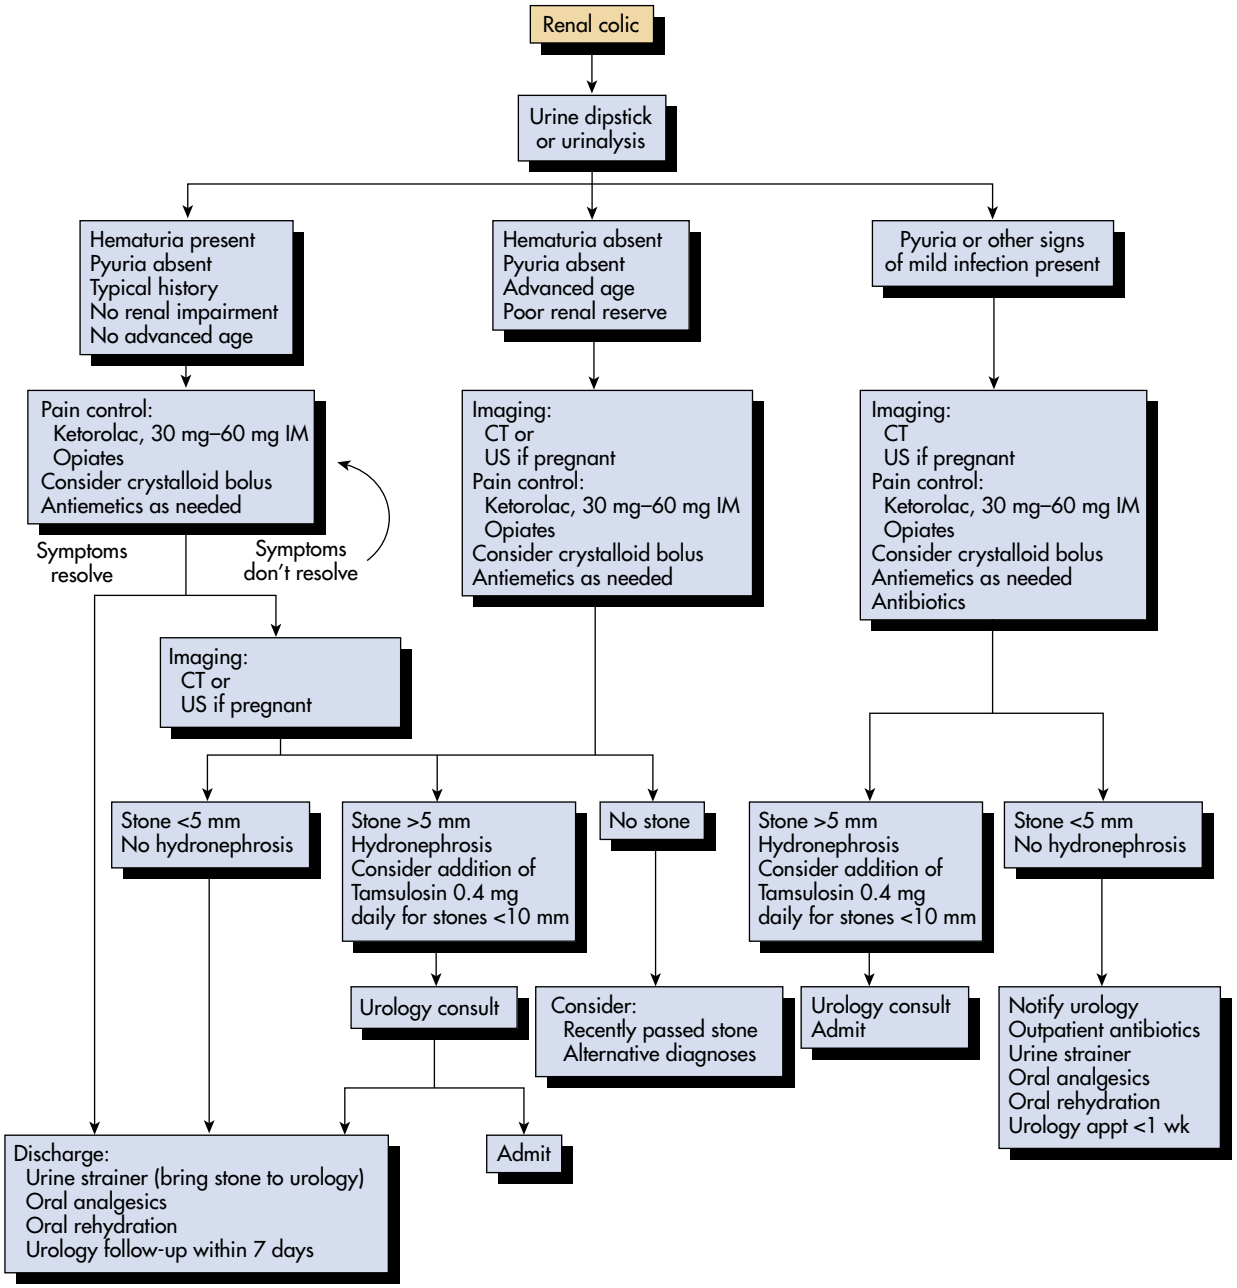

FIG. 2 Guideline algorithm for the evaluation, treatment, and disposition of patients with presumed renal colic. *CT,* Computed tomography; *IV,* intravenously; *US,* ultrasonography. (Modified from Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.)

a 3-mm stone has an approximately 70% probability of spontaneous passage while an 8-mm stone has only a 20% chance.

- Lifetime stone recurrence is as high as 50% and depends on stone factors (composition, size, location, and number of stones) and patient factors (anatomic, genetic, race, comorbidities, hydration status, diet, climate, and occupation).

REFERRAL

Urology referral is appropriate for any urinary stone patient, especially when spontaneous passage is unlikely; if a patient cannot be directly discharged from an emergency department; when there is an obstructing kidney stone and presumed or associated urinary tract infection; when there are large or recurrent stones; and when patients have solitary kidneys or complex anatomy that may predispose them to stones.

PEARLS & CONSIDERATIONS

COMMENTS

- Approximately 60% to 80% of ureteral stones will pass spontaneously within 4 to 6 weeks. Similarly, approximately 60% to 80% of patients will not require admission or surgery for a ureteral stone.

BOX 6 Foods Containing High Levels of Oxalate

Tea (black)
Cocoa
Spinach
Mustard greens
Pokeweed
Swiss chard
Beets
Rhubarb
Okra
Berries (some)
Chocolate
Nuts
Wheat germ
Soy crackers
Pepper

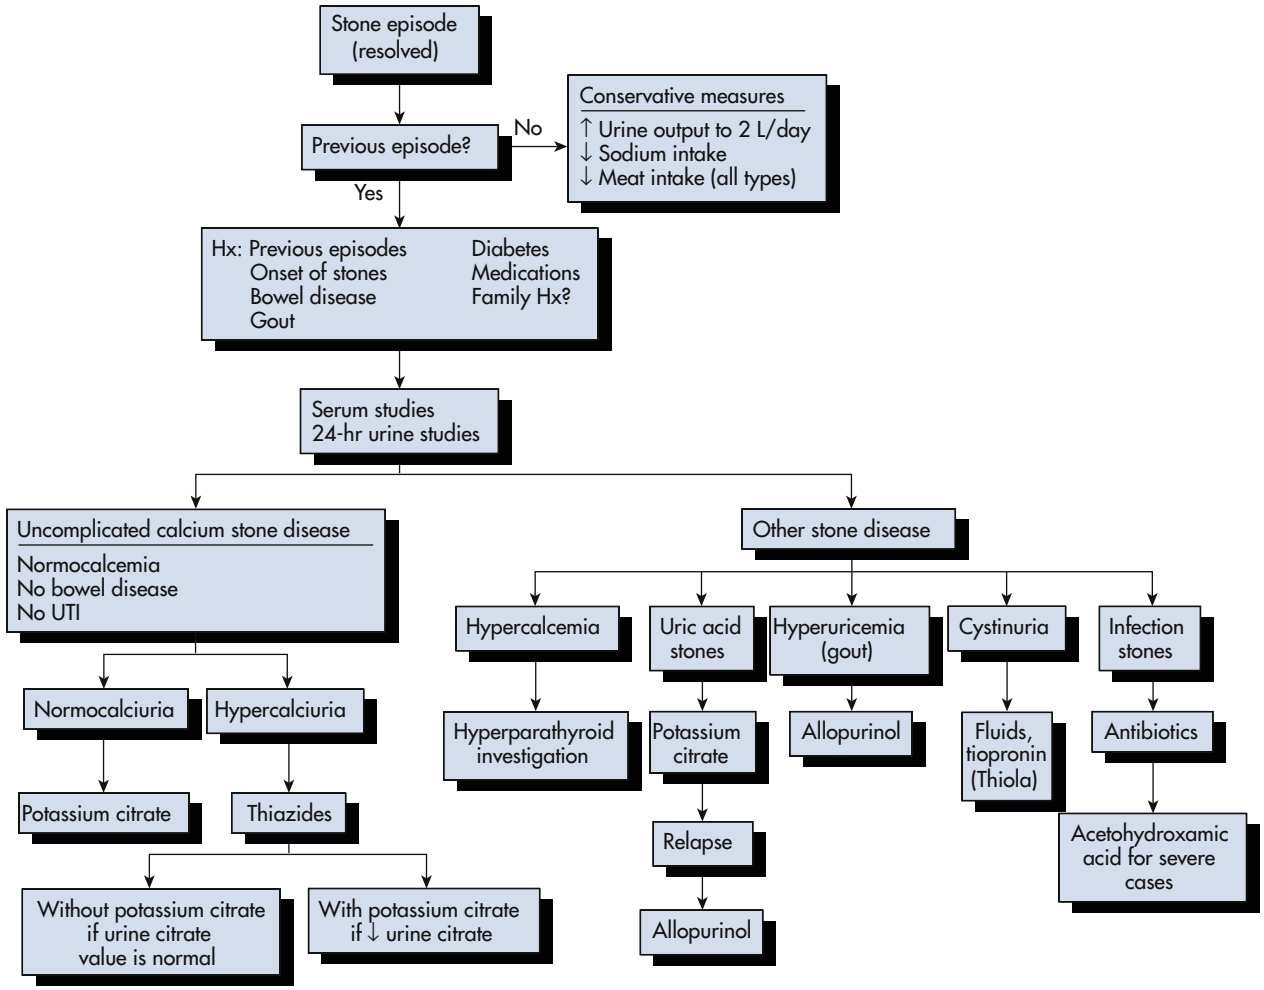

FIG. 3 Simplified treatment algorithm for the evaluation and medical management of urinary lithiasis. *Hx,* History; *UTI,* urinary tract infection. (Modified from CY Pak. From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

TABLE 4 Indications for Percutaneous Nephrolithotomy

Indicator	Description	Treatment
Stone size	≥1.5-2 cm or staghorn	
Composition*,**	Struvite stones	Complete removal necessary to reduce infection and minimize stone recurrence
	Calcium oxalate monohydrate and brushite stones	Difficult to pulverize by SWL
	Cystine stones	Difficult to pulverize by SWL
Stone position	Lower pole stones	Fragments less easily evacuated from dependent lower pole calyces; may not be accessible with ureteroscopy
Anatomic abnormalities	UPJ obstruction; caliceal diverticula; urinary diversion	Prevent passage of fragments after SWL; not always accessible with ureteroscopy
Patient characteristics	Morbid obesity; ureteral obstruction	Stone cannot be placed in focal point of SWL machine; not always accessible with ureteroscopy

SWL or ureteroscopy is the first choice for stone intervention, except in those circumstances that may favor PCNL. *SWL,* Extracorporeal shock wave lithotripsy; *PCNL,* percutaneous nephrolithotomy; *UPJ,* ureteropelvic junction.
*Stone composition can be defined with certainty only by direct stone analysis, but advances in imaging may ultimately provide a means to accurately assess stone composition in situ before treatment, thus allowing the urologist to select the treatment most likely to be successful.
**Ureteroscopy and laser lithotripsy also may be used to treat all stone types, including those listed in this table. Thus, stone size and location ultimately influence PCNL versus ureteroscopy decision.
Modified from Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.

- Imaging is key to diagnosing urolithiases. Ultrasound or KUB is a suitable screening test, while CT scan is most accurate and often determines treatment recommendations.
- Consider NSAIDs as first-line therapy for pain control with kidney stones, unless there are contraindications (e.g., allergy or acute kidney injury).
- Patients should be referred to a urologist if they have large stones unlikely to pass spontaneously, multiple or bilateral stones at presentation, complex stones, or recurrent stones.
- An obstructing urinary stone in the setting of presumed urinary tract infection should be treated with prompt urinary tract drainage via insertion of a ureteral stent or percutaneous nephrostomy tube and with antibiotics. Delays in renal drainage can lead to rapid and life-threatening sepsis.

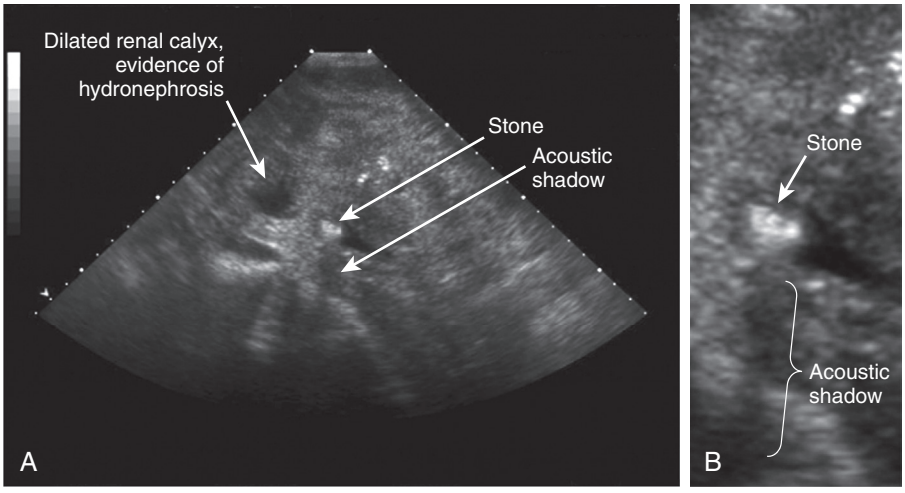

FIG. E1 Ultrasound of renal stone. Ultrasound can be used to assess for renal stones and complications such as hydronephrosis. Stones can be difficult to detect, whereas hydronephrosis is usually readily observed. Because stones are dense, they reflect sound and prevent its through transmission. As a result, stones are echogenic *(bright)* on ultrasound, and cast an acoustic shadow *(black).* **A,** Short-axis view of kidney. **B,** Close-up. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

BASIC INFORMATION

DEFINITION

Urticaria is a pruritic rash involving the epidermis and the upper portions of the dermis caused by localized capillary vasodilation and the release of histamine and other vasoactive mediators. It is followed by transudation of protein-rich fluid in the surrounding tissue and manifests clinically with the presence of raised erythematous, circumscribed lesions with central pallor. Urticaria is classified according to its chronicity into acute (<6-wk duration) and chronic (>6-wk duration).

SYNONYMS

Hives
Wheals

ICD-10CM CODES

L50.0	Allergic urticaria
L50.1	Idiopathic urticaria
L50.2	Urticaria due to cold and heat
L50.8	Other urticaria
L50.9	Urticaria, unspecified
L50.6	Contact urticaria

EPIDEMIOLOGY & DEMOGRAPHICS

- Between 15% and 25% of the population will have at least one episode of urticaria during their lifetime.
- The incidence of chronic urticaria is thought to be around 1.4% annually. It is more common in adults, with the average age of occurrence between the third and fifth decades of life. Females are twice as likely to be affected as males.
- Incidence is increased in atopic patients.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presence of elevated, erythematous, or white circumscribed lesions that change in size and shape over time (Fig. E1) in no specific distribution; they are characterized by extreme pruritus and are evanescent in nature, with individual lesions generally lasting <24 hr in duration and disappearing without scarring. If the patient has persistent symptoms, new lesions typically have a novel distribution.
- Stroking of the skin can lead to urticarial reaction (dermatographism) (Fig. E2).
- Angioedema occurs in approximately 40% of cases of urticaria and is caused by mast cell mediator release in the subcutaneous tissue and deep dermis.

ETIOLOGY

Acute urticaria (Table 1):

- Food allergies (e.g., shellfish [Fig. E3], tree nuts, legumes, milk, eggs)
- Medication allergies (e.g., penicillin, aspirin, sulfonamides, hormone therapy)
- Insect sting allergies (e.g., honey bee, Hymenoptera, fire ant)
- Systemic diseases (e.g., systemic lupus erythematosus, serum sickness, autoimmune thyroid disease, cutaneous mastocytosis)
- Infections (viral infections such as hepatitis B and C, fungal infections, chronic bacterial infections, helminthic); viral upper respiratory infections are the predominant cause
- Contact (nonimmunologic) urticaria (e.g., caterpillars, plants)
- Other: Pregnancy, cryoglobulinemia, hair bleaches, chemicals, saliva, cosmetics, perfumes, pemphigoid, emotional stress, malignancy (lymphomas, endocrine tumors)
- Idiopathic urticaria is diagnosed in approximately 50% of patients with acute urticaria

Chronic urticaria:

- Chronic urticaria (CU) is classified as either chronic spontaneous urticaria (CSU) or chronic inducible urticaria (ClndU), depending on whether the skin lesions appear spontaneously or can be induced.
- Physical stimuli (e.g., pressure, cholinergic, solar, cold/heat, aquagenic, or vibration) are found in approximately 20% of patients.
- CSU results from the pathogenic activation of mast cells and basophils, which leads to the release of proinflammatory mediators.
- Up to 50% of CSU patients may have an autoimmune component with contributions from IgG- and IgE-specific autoantibodies (most commonly anti-IL-24 and anti-FcεR1 antibodies, with the latter found on the surface of dermal mast cells and basophils), although the significance of these antibodies is not known.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Erythema multiforme
- Erythema marginatum
- Erythema infectiosum
- Urticarial vasculitis
- Herpes gestationis
- Drug eruption
- Multiple insect bites
- Bullous pemphigoid
- Mastocytosis
- Mast cell activation syndrome
- Viral exanthema
- Pityriasis rosea
- Atopic dermatitis
- Contact dermatitis
- Henoch-Schönlein purpura

WORKUP

- It is useful to determine whether hives are acute or chronic; a medical history focused on various etiologic factors is necessary before embarking on additional laboratory testing.
- Most cases of acute urticaria resolve spontaneously and diagnostic testing is not required. However, in patients with acute urticaria, it is crucial to consider anaphylaxis before further workup of urticaria because this may require urgent management.
- The etiology of chronic urticaria (CU) is often never determined, and no diagnostic testing may be necessary based on a detailed history and physical examination. Targeted laboratory testing based on clinical findings is appropriate.

LABORATORY TESTS

- If the history is consistent with allergen-induced contact urticaria, skin testing with allergen extracts and screening for dermatographism by attempting to elicit a wheal after application of linear skin pressure should be performed only after withholding antihistamines for 36 to 72 hr to prevent false-negative results.
- CBC with differential, ESR, TSH, and liver function tests should be considered only in patients with a history or physical exam concerning for an underlying systemic condition. Routine testing is not indicated. Even with extensive testing, the cause of chronic urticaria is rarely established.
- Measurement of C4, C1 inhibitor antigenic level and function, and C1q may be helpful in patients who present with angioedema alone. In these patients, C1-inhibitor deficiency should be considered.
- Skin biopsy is helpful in patients with fever, arthralgias, and elevated erythrocyte sedimentation rate. Histologic evidence of leukocytoclasia (neutrophilic infiltration with fragmentation of nuclei) is indicative of urticarial vasculitis.
- When food or contact allergy is suspected in acute urticaria, testing can be performed using skin prick or ImmunoCAP testing.

TREATMENT

NONPHARMACOLOGIC THERAPY

Remove all suspected etiologic agents (e.g., stop aspirin and all nonessential drugs) and avoid any triggers that may have been observed to precipitate an attack.

ACUTE URTICARIA Rx

- Oral antihistamines: Use of second-generation H_1 antihistamines (e.g., cetirizine 10 mg/day, levocetirizine 5 mg/day, loratadine 10 mg/day, fexofenadine 180 mg/day) is preferred over first-generation sedating antihistamines (e.g., hydroxyzine, diphenhydramine). Higher doses of second-generation antihistamines up to 4 times the FDA-approved dose may be required to achieve adequate control of symptoms.
- Leukotriene receptor antagonists (e.g., montelukast) can be added to H_1 antagonists in refractory cases, although the utility of this has not been consistently shown.
- Oral corticosteroids should be reserved for refractory cases and prescribed for a very limited course (e.g., prednisone 20 mg daily or 20 mg twice daily for 5 days).

TABLE 1 Some Causes of Urticaria*

Infections	Eggs†
Bacterial infections	Cheese
Dental abscess	Inhalants
Sinusitis	Animal danders
Otitis	Pollen
Pneumonitis	Contactants
Gastritis	Wool
Hepatitis	Silk
Cholecystitis	Occupational exposure
Cystitis	Potatoes
Vaginitis	Antibiotics
Fungal infections	Cosmetics
Dermatophytes	Dyes
Candida	Hairspray
Other infections/infestations	Nail polish
Scabies	Mouthwash
Helminth	Toothpaste
Protozoa	Perfumes
Trichomonas	Hand cream
Drugs and Chemicals	Soap
Salicylates	Insect repellent
Indomethacin and other, newer nonsteroidal antiinflammatory agents†	Physical stimuli
Opiates†	Light
Radiocontrast material†	Pressure
Penicillin (medication, milk, blue cheese)	Heat
Sulfonamides	Cold
Sodium benzoate	Water
Douches	Vibration
Ear drops or eye drops	Endocrinopathies
Insulin	Thyroid disease
Menthol (cigarettes, toothpaste, iced tea, hand cream, lozenges, candy)	Diabetes mellitus
Tartrazine (vitamins, birth control pills, antibiotics, FDC yellow #5)	Pregnancy
Foods	Menstruation
Nuts	Menopause
Berries†	Systemic diseases
Fish	Rheumatic fever
Seafood	Connective tissue diseases (lupus erythematosus, Sjögren syndrome, rheumatoid arthritis, Still disease, dermatomyositis, polymyositis, other)
Shellfish†	Leukemia
Bananas	Lymphoma
Grapes	Acquired immunodeficiency disease
Tomatoes	Ovarian tumors

*Partial list of most frequently described causes in each category.
†May be mediated by nonimmunologic mechanisms independent of IgE.
From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.

CHRONIC URTICARIA Rx

Stepwise approach for management of chronic urticaria is described in Fig. E4.

- Step 1: Monotherapy with second-generation H_1 antihistamines. Avoidance of triggers (e.g., NSAIDs, alcohol, opiates, physical triggers).
- Step 2: Dose advancement of second-generation antihistamine (up to 4× the daily recommended dose). Consider addition of leukotriene receptor antagonist (e.g., montelukast) or first-generation H_1 antihistamine (hydroxyzine or doxepin) to be taken at bedtime.
- Step 3: Referral to allergy specialist for evaluation and management. Add omalizumab (monoclonal anti-IgE antibody that downregulates surface IgE receptors) to second-generation antihistamine therapy. Ligelizumab is a newer high-affinity humanized monoclonal anti-IgE antibody that in recent trials has shown a higher percentage of patients with chronic spontaneous urticaria achieving compliance control of symptoms than omalizumab.[1]
- Step 4: If adequate control is not reached by 18 wk, alternative agents should be considered, including antiinflammatory (dapsone, hydroxychloroquine, sulfasalazine, methotrexate) or immunosuppressive agents (cyclosporine A, mycophenolate, tacrolimus, sirolimus).
- Step 5: Consider addition of immunomodulatory biologic agents (TNF-α inhibitor, IL-1 antagonist) or alternative therapies such as UV light therapy, IVIG, or plasmapheresis.
- Patients should be evaluated at each visit and if symptoms are well managed, should be considered for step down in treatment.

DISPOSITION

- Most cases of urticaria resolve within 6 wk.
- More than 50% of patients may not achieve satisfactory control of chronic urticaria with antihistamines alone and may require additional therapies. The median duration of CU is between 3 to 5 yr, but it can often be present for much longer durations.

PEARLS & CONSIDERATIONS

COMMENTS

- Topical treatment (e.g., starch baths or oatmeal baths) may be temporarily soothing in selected patients; however, they are not recommended for long-term control of CU.
- If individual urticarial lesions leave residual ecchymoses, pigmentation and/or lesions that typically last >24 hr at a single location, consider skin biopsy to evaluate for urticarial vasculitis.
- **Be judicious when prescribing NSAIDs in CU patients, as up to 30% of these patients will experience an exacerbation of urticaria and/or angioedema.**

FIG. E2 Dermatographism. Stroking of the skin leads to the urticarial reaction. (From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

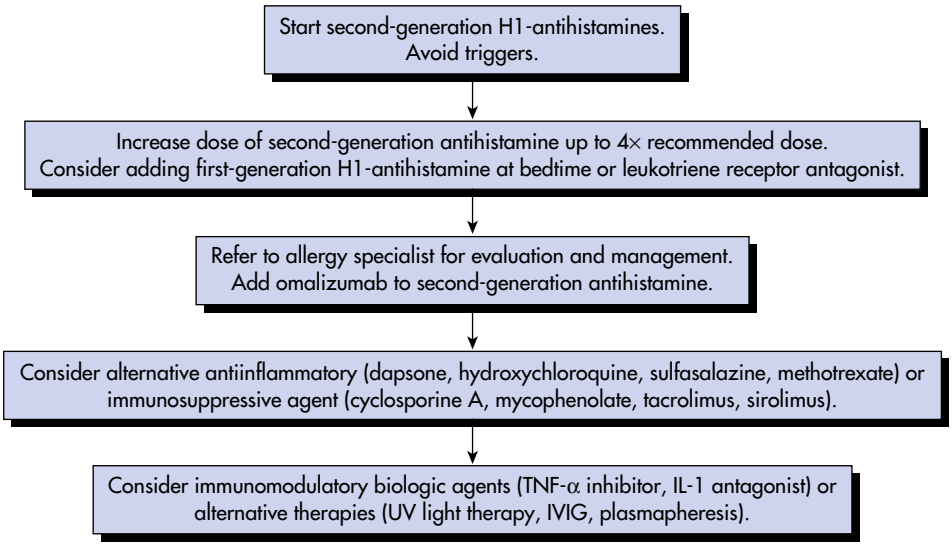

FIG. E4 Stepwise treatment diagram for chronic urticaria. Stepwise approach for management of chronic urticaria is described.

- Step 1: Monotherapy with second-generation H_1-antihistamines. Avoidance of triggers (e.g., NSAIDs, alcohol, opiates, physical triggers).
- Step 2: Dose advancement of second-generation antihistamine (up to 4 times the daily recommended dose). Consider addition of leukotriene receptor antagonist (e.g., montelukast) or first-generation H_1 antihistamine (hydroxyzine or doxepin) to be taken at bedtime.
- Step 3: Referral to allergy specialist for evaluation and management. Add omalizumab (monoclonal anti-IgE antibody that downregulates surface IgE receptors) to second-generation antihistamine therapy.
- Step 4: If adequate control is not reached by 18 wk, alternative agents should be considered including antiinflammatory (dapsone, hydroxychloroquine, sulfasalazine, methotrexate) or immunosuppressive agents (cyclosporine A, mycophenolate, tacrolimus, sirolimus).
- Step 5: Consider addition of immunomodulatory biologic agents (tumor necrosis factor-α [TNF-α] inhibitor, interleukin-1 [IL-1] antagonist) or alternative therapies such as ultraviolet (UV) light therapy, Intravenous immunoglobulin (IVIG), or plasmapheresis.
- Patients should be evaluated at each visit and if symptoms are well managed, should be considered for step down in treatment.

Uterine Fibroids PTG ALG

BASIC INFORMATION

DEFINITION

Uterine fibroids, also called leiomyomas or uterine myomas, are benign tumors of muscle cells of the myometrium and connective tissue. The incidence of malignancy is less than 1 in 1000. They are typically discrete nodular tumors that vary in size and number.

Fibroids are classified by location in the uterus relative to the myometrium.

- Subserosal: Located directly underneath the uterine serosa
- Intramural: Located in the myometrium proper
- Submucosal: Also known as intracavitary as they are located adjacent to the endometrium and protrude into the uterine cavity
- Pedunculated: Located on a pedicle or stalk, either from the serosa or in the cavity

Fibroids can also be located within the cervix, broad ligament, or diffusely in the body such as within the abdomen on peritoneum or within skin. Parasitic fibroids acquire a blood supply from a nonuterine source (Fig. 1).

SYNONYMS

Uterine leiomyomas
Uterine myomas
Fibroids
Leiomyomas

ICD-10CM CODES

D25.0 Submucous leiomyoma of uterus
D25.1 Intramural leiomyoma of uterus
D25.2 Subserosal leiomyoma of uterus
D25.9 Leiomyoma of uterus, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Estimated cumulative incidence of 70% to 80% in women by age 50.
- The most common benign solid pelvic tumor diagnosed in women and the most common reason for benign hysterectomy.
- More common in African American women than in Caucasian women.
- May occur singly but are often multiple.
- Approximately 50% of all fibroids are estimated to produce symptoms that impact women including restriction of social, physical, and work activities.
- Frequently diagnosed incidentally on pelvic examination.
- There is increased familial incidence.
- Potential to enlarge during pregnancy as well as regress after menopause.
- Approximately 200,000 hysterectomies, 30,000 myomectomies, and thousands of selective uterine-artery embolizations and high-intensity focused ultrasound procedures are performed annually in the U.S. to remove or destroy uterine fibroids.[1]

[1] Bulun SE: Uterine fibroids, *N Engl J Med* 369:1344-1355, 2013.

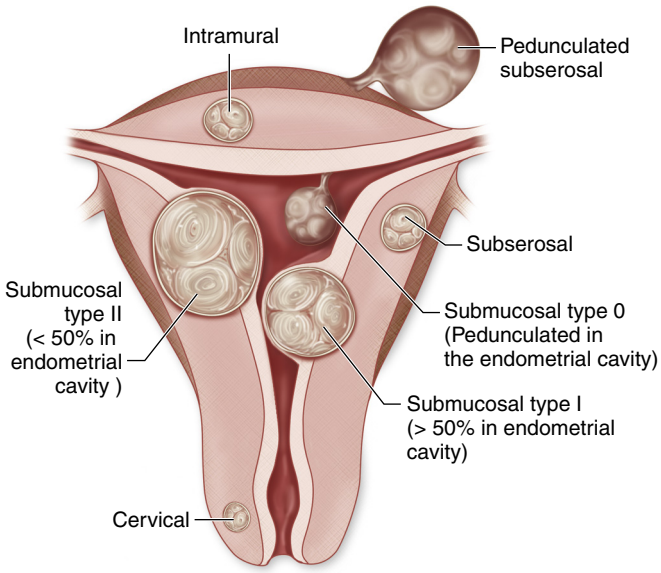

FIG. 1 Drawing of uterus in the coronal plane, illustrating possible location of uterine leiomyomas. (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, Saunders.)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Enlarged, irregular uterus on pelvic examination
- Uterine fibroids are asymptomatic in up to 50% of affected women
- Presenting symptoms (when present):
  1. Abnormal uterine bleeding (most common)
  2. Chronic pelvic pain (dysmenorrhea, dyspareunia, pelvic pressure)
  3. Bulk symptoms (bloating, increase in abdominal girth)
  4. Anemia
  5. Acute pain (torsion of pedunculated fibroid, infarction, and degeneration)
  6. Urinary symptoms (frequency from bladder pressure, partial ureteral obstruction, complete ureteral obstruction, incontinence in setting of prolapse)
  7. GI symptoms (rectosigmoid compression with constipation or intestinal obstruction, pain with defecation)
  8. Prolapse through cervix of pedunculated submucosal fibroid
  9. Infertility
  10. Pregnancy complications including preterm birth, small fetus for gestational age, malpresentation, and potentially recurrent miscarriage

ETIOLOGY

Not well understood. It is suggested that fibroids arise from an original single smooth muscle cell in the myometrium. Each individual fibroid is monoclonal (all the cells are derived from one progenitor myocyte). Malignant degeneration of preexisting leiomyoma is extremely uncommon (<0.5%). There is a racial disparity in the prevalence, suggesting a genetic component, with most fibroids having a normal chromosomal makeup. A small group of women have an autosomal dominant disorder, hereditary leiomyomatosis and renal cell carcinoma syndrome, in which there is a genetic mutation in the fumarate hydratase gene, causing diminished suppressor function in fibroid formation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ovarian mass (neoplastic, nonneoplastic, endometrioma)
- Adenomyosis
- Endometriosis
- Endometrial polyp
- Endometrial carcinoma
- Leiomyosarcoma/uterine carcinosarcoma
- Inflammatory mass (reproductive organ or GI origin)
- Pregnancy

WORKUP

- Complete pelvic examination, including speculum exam as well as bimanual exam
- Estimation of size of uterus/mass and location of fibroids via imaging
- Endometrial sampling may be indicated (biopsy or dilation and curettage) when abnormal bleeding and pelvic mass are present
- If significant urinary symptoms are prominent, intravenous pyelogram to rule out impingement on urinary system

LABORATORY TESTS

- Pregnancy test
- Complete blood count
- Blood urea nitrogen/creatinine
- Thyroid stimulating hormone

IMAGING STUDIES

- Pelvic ultrasound (Fig. 2) is useful as a primary diagnostic modality. Transvaginal ultrasound commonly has higher diagnostic accuracy.
- MRI scan (Fig. E3) is helpful in planning treatment if malignancy is strongly suspected.

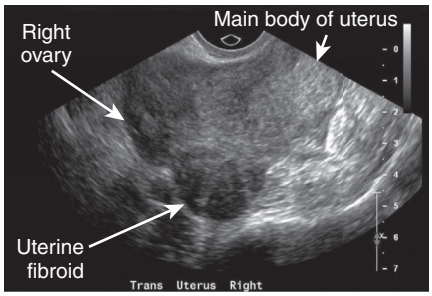

FIG. 2 Fibroid uterus: Endovaginal ultrasound. Ultrasound is the primary modality used for evaluation of uterine fibroids (leiomyomas). Typical features include a well-circumscribed appearance. Fibroids may be hypoechoic or hyperechoic relative to the uterus. They may be exophytic or intramural, or they may project into the uterine cavity. Whereas malignant uterine tumors may invade adjacent structures, a fibroid is contained within the uterine serosa. Uterine tumors, both benign and malignant, can show central necrosis, which usually appears hypoechoic with ultrasound. In this 38-yr-old woman, the fibroid is exophytic. The right ovary lies adjacent and is difficult to distinguish in this case. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

Also important to localize fibroids, especially if myomectomy is contemplated. Size, number, and location of fibroids are also important if a minimally invasive myomectomy is considered.

- Diagnostic hysteroscopy can be performed in the office and may provide direct evidence of intrauterine pathology or submucosal leiomyoma that distorts uterine cavity.
- Saline infusion sonography can be helpful in determining location and degree of intrusion into uterine cavity.

Rx TREATMENT

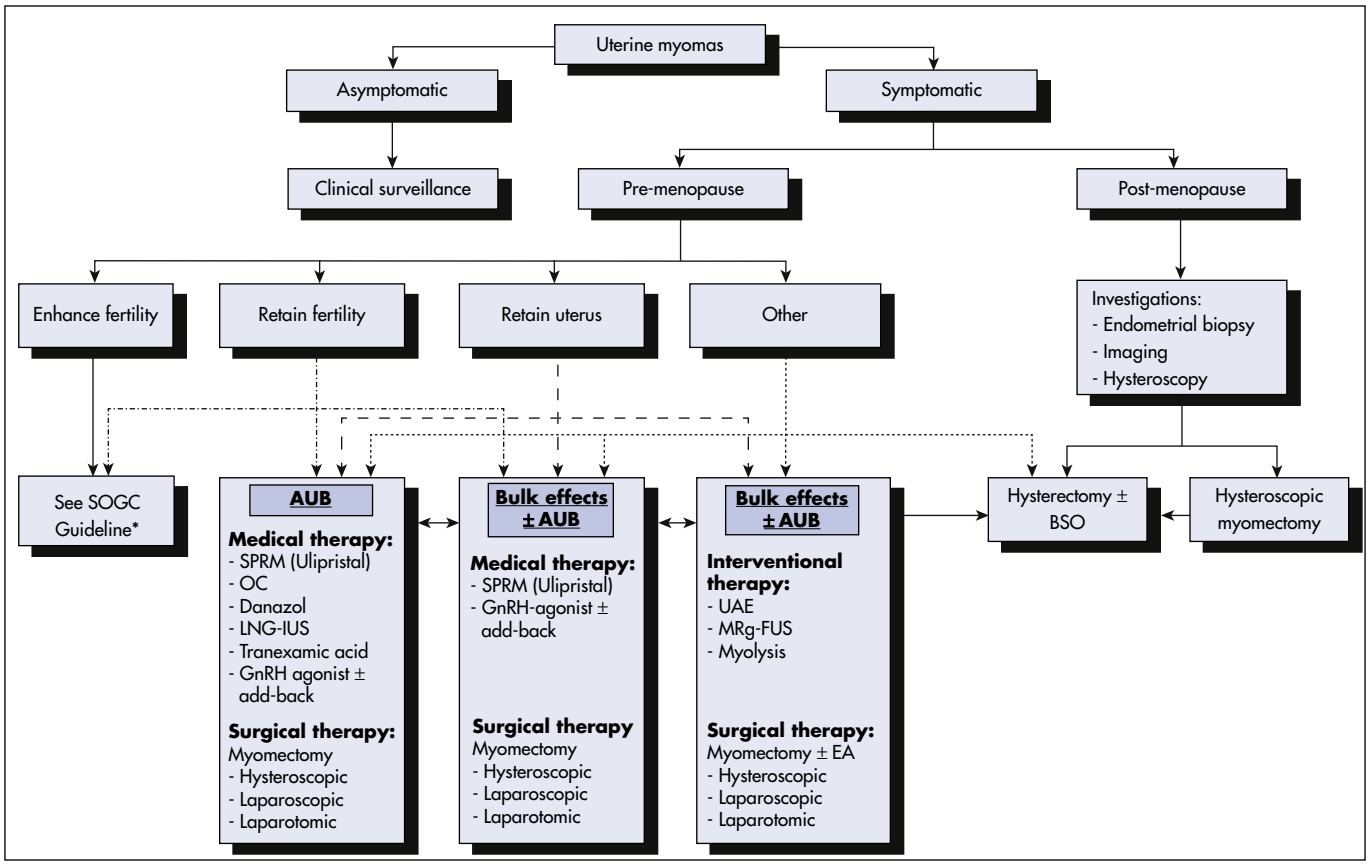
Management (Fig. 4) should be based on primary symptoms and may include observation with close follow-up, medical management, temporizing surgical therapies, embolization, or definitive surgical procedures. Treatment is generally indicated if bleeding is requiring blood transfusions, renal function is affected by size of the enlarged fibroid uterus, or when symptoms are present and are severe enough to be unacceptable to the patient.

NONSURGICAL Rx

- Patient observation and follow-up with periodic repeat pelvic examinations to ensure that tumors are not growing rapidly.
- Hormonal therapies can reduce bleeding symptoms and many have the added benefit of contraception. There is no evidence that exogenous estrogen or progestin increases risk of myomas.
  1. Combined hormonal methods with estrogen and progestin, including combined oral contraceptives, contraceptive patch, contraceptive vaginal ring.
  2. Progestin-only agents including oral progestins, intramuscular progestin injection, subcutaneous progestin implant, levonorgestrel intrauterine device (IUD).
  3. Progesterone IUD can be used to treat menorrhagia, but intracavitary fibroids may be a relative contraindication.
  4. Ulipristal acetate, not yet available in the U.S. for treatment of fibroids, is a selective progesterone-receptor modulator (SPRM) that acts on progesterone receptors in myometrial and endometrial tissue and inhibits ovulation without significant effects on estradiol levels or antiglucocorticoid activity. Recent trials showed that treatment with ulipristal acetate for 13 wk effectively controlled excessive bleeding due to uterine fibroids and reduced the size of the fibroids. Phase 3 trials for SPRM are ongoing in the U.S.
- Gonadotropin-releasing hormone (GnRH) agonist use results in 40% to 60% reduction in uterine volume within 3 months of initiating treatment. Hyperestrogenism, reversible bone loss, and hot flushes are associated with use. Consider low-dose progesterone replacement to minimize hypoestrogenic effects.
  1. Regrowth and return of bleeding symptoms occurs in approximately 50% of women treated within a few months after cessation.
  2. Indications for GnRH:
     a. Fertility preservation in women with large myomas before attempting conception or preoperative myectomy treatment
     b. Anemia treatment to normalize hemoglobin before surgery
     c. Women approaching menopause to avoid surgery
     d. Preoperative for large myomas to make vaginal hysterectomy, hysteroscopic resection/ablation, or laparoscopic destruction more feasible
     e. Women with medical contraindications for surgery
  3. Personal or medical indications for delaying surgery: Use of GnRH agonists may alter the consistency of the fibroid, making myomectomy more challenging.
- Nonhormonal medical therapies:
  1. Nonsteroidal antiinflammatory drugs.
  2. Tranexamic acid, an oral antifibrinolytic agent that prevents fibrinolysis of menstrual fluid, can decrease menorrhagia by 40% to 65%. Side effects include abdominal cramps, headaches, fatigue, and increase risk of venous thromboembolism.
- Other drugs used and under investigation:
  1. Danazol: Androgen and multienzyme inhibitor of steroidogenesis
  2. Mifepristone: Antiprogesterone shown to reduce the fibroid volume by 40% to 50% with amenorrhea
  3. Raloxifene: Selective estrogen receptor modulator, either alone or with a GnRH agonist, shown to reduce the fibroid volume 70% up to 1 yr but only in postmenopausal women
  4. Fadrozole: Aromatase inhibitor reported to have produced a 71% reduction in volume that is not yet available in the U.S.
  5. Vilaprisan: Selective progesterone receptor modulator (SPRM) currently in phase 3 trials showing decreasing amenorrhea rates and reduction in fibroid size

SURGICAL Rx

- Indications:
  1. Abnormal uterine bleeding with anemia refractory to hormonal therapy
  2. Chronic pain with severe dysmenorrhea, dyspareunia, or lower abdominal pressure/pain
  3. Acute pain, torsion, or prolapsing submucosal fibroid
  4. Urinary symptoms or signs such as hydronephrosis
  5. Rapid uterine enlargement premenopausal or any growth after menopause
  6. Infertility or recurrent pregnancy loss with submucous leiomyoma as only finding
  7. Enlarged uterus with compression symptoms or discomfort
- Procedures:
  1. Hysterectomy (definitive procedure): Vaginal, laparoscopic, robotic, or abdominal approach, dependent on surgical preference/expertise and uterine size.
  2. Myomectomy (to preserve fertility or due to patient preference): May be performed via abdominal, laparoscopic, or robotic approach.
  3. Vaginal myomectomy for prolapsed pedunculated submucous fibroid.
  4. Hysteroscopic resection: Typically at least 50% of the fibroid must be intracavitary for a hysteroscopic approach to be successful.
  5. Radiofrequency volumetric thermal ablation: FDA-approved uterine-sparing procedure in which laparoscopic ablation of individual fibroids is performed. This causes myolysis (necrosis of the tissue) resulting in the fibroid shrinking.
  6. Uterine artery embolization (UAE): Safe and effective short-term alternative to surgery, but its less invasive nature should be balanced against a higher rate for treatment failure or complications



BSO: Bilateral salpingo-oophorectomy; MRg-FUS: magnetic resonance-guided focused ultrasound; OC: oral contraceptives

FIG. 4 Algorithm for the management of uterine fibroids. *GnRH,* Gonadotropin-releasing hormone; *UAE,* uterine artery embolization. (From Vilos GA et al: The management of uterine leiomyomas, *J Obstet Gynaecol Can* 37(2):163, 2015. *Carranza-Mamane B, Havelock J, Hemmings R: Society of Obstetrics and Gynaecology Canada Reproductive Endocrinology and Infertility Committee: The management of uterine fibroids in women with otherwise unexplained infertility. SOGC Clinical Practice Guidelines, *J Obstet Gynaecol Can* 2015.)

at 5 yr (32%) versus the surgery group (4%). Age 40 yr and under at embolization and history of previous myomectomy are significant predictors of embolization failure. If the patient wishes to preserve future fertility, UAE should not be performed.

7. Endometrial ablation: Performed specifically to decrease menorrhagia.
8. MRI-guided focus ultrasound surgery for fibroids is a noninvasive thermoablative procedure that allows high-energy ultrasound waves to converge on a fibroid localized by MRI. Note, there is limited availability of this procedure.

COMPLICATIONS

- Red degeneration occurs when the fibroid outgrows its blood supply leading to hemorrhage in the center of the fibroid. This is typically seen in the second trimester of pregnancy but is a rare occurrence.
- Leiomyosarcoma (<0.1%). Recent concern has been voiced by the U.S. FDA regarding the use of morcellation in minimally invasive surgery because of the possibility of spreading occult malignancy in the peritoneal cavity.

REFERRAL

Consultation with gynecologic oncologist if suspicious of malignancy

BASIC INFORMATION

DEFINITION

Cancers of the uterine corpus include tumors originating from the endometrium (endometrial stromal cancers). The most common type of endometrial cancer is adenocarcinoma, which includes endometrioid, clear cell, mucinous, and papillary serous subtypes (see separate chapter on endometrial cancer). Uterine cancer also includes tumors that result from abnormal proliferation of cells originating from the connective, muscular, vascular, or fibrous tissue elements of the uterine wall (myometrium).

SYNONYMS

Leiomyosarcomas
Endometrial stromal sarcoma
Malignant mixed Müllerian tumors
Adenosarcomas

ICD-10CM CODES

C54.1 Malignant neoplasm of endometrium
C54.2 Malignant neoplasm of the myometrium
C54.0 Malignant neoplasm of isthmus uteri
C54.8 Malignant neoplasm of overlapping sites of corpus uteri

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Incidence of uterine cancer (including endometrial) is 27 per 100,000 women per yr, with 5 deaths per 100,000 women as of 2016. Endometrial cancer remains the most common gynecologic malignancy in the U.S. Uterine cancer is one of the few cancers with increasing incidence and mortality in the U.S., reflecting in part increases in the prevalence of obesity since the 1980s. It is the fourth most common cancer diagnosed and the sixth most common cause of cancer death among U.S. women.[1]
PREVALENCE: Uterine sarcoma accounts for approximately 8% of all cancers of the uterine corpus and is associated with poor prognosis.
MEAN AGE AT DIAGNOSIS: 60 yr
RISK FACTORS: Box 1 describes risk factors for uterine sarcoma

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Abnormal vaginal bleeding is the most common symptom (90% of women with diagnosis).
- Vaginal discharge also may be a presenting symptom (10% of these patients have nonbloody discharge).
- May also present as pelvic pain or pressure and pelvic mass on examination (10% of women with uterine sarcoma)
- Urinary symptoms
- Abdominal pain or distension
- Weight loss

[1]Henley SJ et al: Uterine cancer incidence and mortality—United States, 1999-2016, *MMWR* 67(48):1333-1338, 2018.

ETIOLOGY

- The exact etiology is unknown.
- Endometrial cancer is possibly related to the balance between progesterone and estrogen in the body.

DIAGNOSIS

- Endometrial cancer: Endometrial biopsy or dilation and curettage with histologic evidence of malignancy.
- Uterine sarcoma: Postsurgical histological examination of uterine tissue

DIFFERENTIAL DIAGNOSIS

- Endometrial hyperplasia
- Leiomyoma

WORKUP

Diagnosis is made histologically by biopsy for abnormal bleeding. Workup includes biopsy (in the office or operating room, in conjunction with hysteroscopy) and imaging (see below). Histologic criteria include mitotic index, cellular atypia, and coagulative necrosis.

LABORATORY TESTS

- CBC depending on level of bleeding
- CA-125 (high levels can be a sign of metastasis, not diagnostic, not always elevated)

IMAGING STUDIES

- Pelvic ultrasound is a lower-cost method of detecting uterine corpus mass or thickened endometrial lining. Features concerning for uterine sarcoma: heterogeneous texture, central necrosis, irregular vessel distribution.
- Chest x-ray is usually done as routine preoperative testing.
- CT scans (Fig. 1), MRI, and PET are useful for assessing tumor spread once diagnosis is made.

STAGING

Staging of endometrial carcinoma and uterine adenosarcoma is summarized in Tables 1 and 2.

TREATMENT (TABLE 3)

NONPHARMACOLOGIC THERAPY

- Surgical excision is the mainstay of treatment, with or without lymph node mapping and with or without peritoneal lavage or peritoneal biopsies. Degree of removal and exploration depends on grading, staging, and type of cancer.
- Endometrial stromal sarcoma: Stage 1 disease is usually followed up by surveillance. Stage 2 or higher can be offered endocrine therapy or radiation therapy.
- Leiomyosarcoma: Usually followed with surveillance. Chemotherapeutic agents can be considered for stage 3 or higher; they have produced only partial and short-term responses

BOX 1 Risk Factors for Uterine Sarcoma

- Nulliparity
- Obesity
- History of pelvic radiation
- Exposure to tamoxifen

From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, Saunders.

DISPOSITION

- Survival varies with each type of sarcoma but is generally very poor. Box 2 describes uterine prognostic factors.
- Five-yr survival for grade I endometrial stromal sarcoma is 91% and drops to 42% for grade III.
- Five-yr survival for leiomyosarcoma ranges from 76% for stage 1 to 29% for stage 4.
- Five-yr survival for undifferentiated sarcoma ranges from 70% for stage 1 to 23% for stage 4.

REFERRAL

Uterine sarcoma should be managed by a gynecologic oncologist and radiation oncologist. Key

TABLE 1 International Federation of Gynecology and Obstetrics 2009 Staging for Endometrial Carcinoma (Including Carcinosarcoma)

Stage	
I_A	Tumor confined to uterine corpus, <50% myometrial invasion
I_B	Tumor confined to uterine corpus, ≥50% myometrial invasion
II	Tumor invades cervical stroma but confined to uterus
III_A	Tumor invades uterine serosa or adnexa
III_B	Involvement of vagina or parametrium
III_{C1}	Metastasis to pelvic lymph nodes
III_{C2}	Metastasis to paraaortic lymph nodes
IV_A	Invasion of bladder or bowel mucosa
IV_B	Distant metastases including intraabdominal metastasis, inguinal lymph nodes, or both

From Niederhuber JE:*Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE 2 International Federation of Gynecology and Obstetrics 2009 Staging for Uterine Adenosarcoma

Stage	
I_A	Tumor limited to endometrium
I_B	Tumor limited to uterus, <50% myometrial invasion
I_C	Tumor limited to uterus, ≥50% myometrial invasion
II_A	Adnexal involvement
II_B	Extrauterine pelvic tissue involvement
III	Involvement of abdominal tissues
III_A	1 site
III_B	>1 site
III_C	Metastases to pelvic, paraaortic lymph nodes, or both
IV_A	Tumor invades bladder or rectum
IV_B	Distant metastases

From Niederhuber JE:*Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

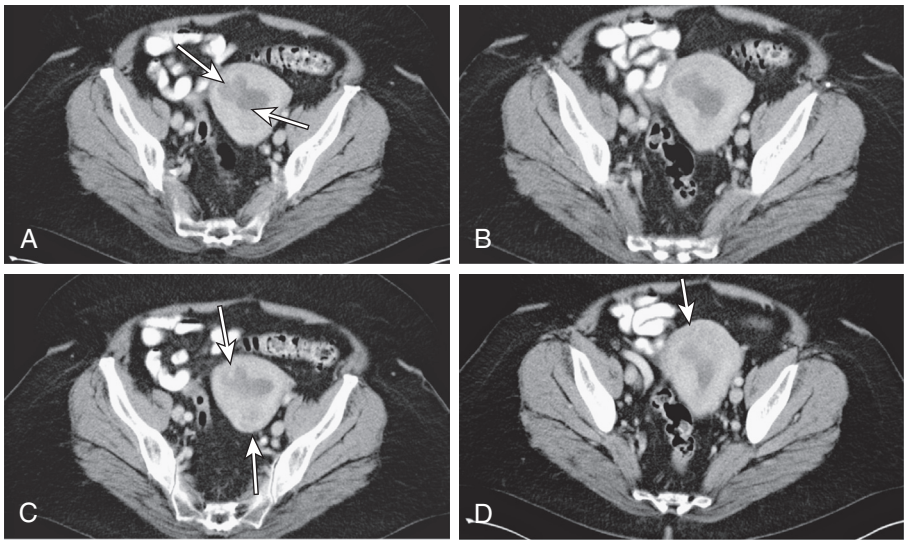

FIG. 1 A 50-year-old patient with uterine sarcoma. A, Axial contrast-enhanced computed tomographic (CT) image. Low-attenuation lobulated and infiltrating soft tissue fills the endometrial canal *(arrows),* extending into the myometrium. **B,** Axial contrast-enhanced CT image showing same as **A.** Low-attenuation, lobulated and infiltrating soft tissue fills the endometrial canal, extending into the myometrium. **C,** Axial contrast-enhanced CT image. Low-attenuation lobulated and infiltrating soft tissue fills the endometrial canal. Subtle myometrial invasion is seen anterior and posterior *(arrows).* **D,** Axial contrast-enhanced CT image. Low-attenuation lobulated and infiltrating soft tissue fills the endometrial canal *(arrow),* showing same. Subtle myometrial invasion is seen fundally. (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, Saunders.)

TABLE 3 National Comprehensive Cancer Network Guidelines for Treatment of Uterine Serous, Clear Cell Endometrial Carcinoma, and Carcinosarcoma

Stage	Adjuvant Treatment
I_A without myometrial invasion	Observe, or chemotherapy, or VBT, or combination therapy
I_A with myometrial invasion, I_B, II	Chemotherapy ± tumor-directed RT, or whole abdominopelvic RT ± VBT
III, IV (adequately debulked)	Chemotherapy ± tumor-directed RT, or whole abdominopelvic RT ± VBT
III, IV (inadequately debulked)	Chemotherapy

RT, Radiation therapy; *VBT,* vaginal brachytherapy.
From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

BOX 2 Uterine Sarcoma Prognostic Factors

- Tumor stage
- Tumor grade
- Tumor size
- Patient age
- Vascular space involvement
- Mitotic count
- Residual disease at surgery
- Adjuvant chemotherapy

From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, Saunders.

BOX 3 Uterine Sarcoma: Key Points

- The disease mainly affects postmenopausal women.
- Most patients present early with postmenopausal bleeding.
- The primary treatment is hysterectomy.
- Adjuvant radiotherapy to the pelvis is used if poor prognosis features in stage 1 or if spread has occurred beyond the corpus.

From Greer IA et al: *Mosby's color atlas and text of obstetrics and gynecology,* London, 2001, Harcourt.

points in the management of uterine sarcoma are described in Box 3.

Uveitis

BASIC INFORMATION

DEFINITION

Uveitis is inflammation of the uveal tract, including the iris, ciliary body, and choroid. It may also involve other contiguous structures such as the sclera, cornea, retina, and vitreous humor (Fig. E1).

SYNONYMS

Anterior uveitis (iritis, iridocyclitis)
Intermediate uveitis (pars planitis)
Posterior uveitis (choroiditis)
Acute or chronic uveitis
Granulomatous or nongranulomatous uveitis

ICD-10CM CODES

H20.0	Acute and subacute iridocyclitis
H20.1	Chronic iridocyclitis
20.8	Other iridocyclitis
H20.9	Unspecified iridocyclitis
H44.131	Sympathetic uveitis, right eye
H44.132	Sympathetic uveitis, left eye
H44.133	Sympathetic uveitis, bilateral
H44.139	Sympathetic uveitis, unspecified eye

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Common; busy ophthalmologist will see two or more cases per wk.
PEAK INCIDENCE: Middle age or older
PREVALENCE (IN U.S.): 17 cases per 100,000 persons
PREDOMINANT SEX: None
PREDOMINANT AGE: 38 yr. Although uveitis is less common in children than adults, it is believed to be more severe with an increased risk for vision-threatening complications.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms of uveitis depend on the site of involvement and whether process is acute or insidious:
  1. Acute anterior uveitis: Pain and photophobia. Vision may not be affected initially.
  2. Posterior uveitis: Floaters, hazy vision. Involvement of the retina may produce blind spots or flashing lights.
  3. Insidious anterior uveitis: Symptoms may not be present until scarring, cataracts, and loss of vision occur.
- Photophobia
- Blurred visual acuity
- Irregular pupil (with synechiae, inflamed iris attaching to the lens)
- Hazy cornea
- Abnormal cells and flare in anterior chamber or vitreous humor noted with slit lamp examination
- Retinal hemorrhage, vascular sheathing
- Conjunctival injection, particularly around the iris (ciliary flush)
- Keratitic precipitates (white precipitates on the posterior surface of the cornea)
- Hazy vitreous
- Retinal inflammation
- Iris nodules

ETIOLOGY

- Infections: Herpes simplex and zoster virus, cytomegalovirus, toxoplasmosis, tuberculosis, syphilis, HIV
- Systemic disorders (autoimmunity): Sarcoidosis, Behçet syndrome, HLA-B27–associated diseases (e.g., ankylosing spondylitis, psoriatic arthritis), inflammatory bowel disease, juvenile idiopathic arthritis (Fig. E2)
- Idiopathic (>50% of patients)
- Significant intraocular inflammation after any eye surgery should alert one to the possibility of infection (endophthalmitis); this should be immediately referred to the ophthalmologist/surgeon

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Glaucoma (particularly acute angle closure)
- Conjunctivitis
- Retinopathy or neovascular glaucoma
- Keratitis
- Scleritis
- Episcleritis
- Masquerading syndromes: Lymphoma, uveal melanoma, metastases (breast, lung, renal), leukemia, retinitis pigmentosa, retinoblastoma

WORKUP

Comprehensive eye examination including slit lamp exam, dilated ophthalmoscopy

LABORATORY TESTS

- Complete blood count
- Laboratory tests for specific inflammatory causes cited previously in "Workup" (e.g., antinuclear antibody, erythrocyte sedimentation rate, syphilis [VDRL], HLA-B27, purified protein derivative, Lyme titer, angiotensin converting enzyme [ACE])
- Urinalysis

IMAGING STUDIES

- Chest radiograph in suspected sarcoidosis, tuberculosis, histoplasmosis
- Sacroiliac radiograph in suspected ankylosing spondylitis

TREATMENT

ACUTE GENERAL Rx

- Corticosteroids are the mainstay of therapy for noninfectious causes. The route and dosage of medication depends on the location of inflammation, the severity, and the presence of systemic disease. Cycloplegic drops (cyclopentolate, homatropine bid to qid) and topical steroids (prednisone acetate 1% 1 gtt qh during day, prn at night until favorable response, then q4 to 6h); avoid topical corticosteroids in infectious uveitis. Periocular corticosteroid injections can be used for posterior disease; they have the advantage of achieving high intraocular levels of steroids without the systemic side effects of oral corticosteroids.
- Antibiotics for bacterial infections and antiviral agents, when infection is suspected, should be started to prevent retinal damage.
- Systemic steroids if appropriate for the underlying disease. Systemic corticosteroid therapy is generally reserved for patients with systemic disorders and those with bilateral disease that is refractory to local medication or those with major ocular disability or retinitis.
- Antimetabolites when indicated. Immunosuppressive medications used in steroid-dependent or refractory uveitis include methotrexate, sulfasalazine, azathioprine, cyclosporine, and tacrolimus. These medications can have significant toxicity and should be prescribed only by physicians experienced with their use. May work in cooperation with rheumatologist.
- High-dose IV daclizumab has been reported as effective in reducing active inflammation in active juvenile idiopathic arthritis (JIA)-associated anterior uveitis. Additional trials are needed to better assess efficacy and safety. Phase 3 trials with adalimumab as a glucocorticoid-sparing agent for the treatment of noninfectious uveitis revealed a lower risk of uveitic flare or visual impairment and more adverse events and serious adverse events than placebo.

REFERRAL

Urgent referral to ophthalmologist for diagnosis and treatment[1]

PEARLS & CONSIDERATIONS

COMMENTS

Chronic anterior uveitis is the most common form of intraocular inflammation in children. JIA is the most common cause.

Vaginal Bleeding During Pregnancy

BASIC INFORMATION

DEFINITION

Bleeding per vagina at any time during pregnancy must be regarded as abnormal and is associated with an increased likelihood of pregnancy complications.

SYNONYM

Hemorrhage

ICD-10CM CODES

O20.8	Other hemorrhage in early pregnancy
O20.9	Hemorrhage in early pregnancy, unspecified
O03.9	Complete or unspecified spontaneous abortion
O44.10	Placenta previa with hemorrhage, unspecified trimester
O45.8X9	Other premature separation of placenta, unspecified trimester

EPIDEMIOLOGY & DEMOGRAPHICS

- Common in U.S. and occurs in women of childbearing age.
- 20% to 25% of patients have vaginal spotting/bleeding in the first trimester.
- Early vaginal bleeding increases the risk of miscarriage (50%) and preterm birth. Some studies have also noted an increased risk of small-for-gestational-age fetal measurements, low birth weight, and possible intrauterine fetal demise.
- Ectopic pregnancy is the leading cause of maternal mortality in the first trimester. 1% to 2% of all pregnancies are ectopic with a recently increased risk of cesarean scar pregnancy.
- Placental abruptions are noted in 1 in 150 pregnancies with an increased recurrence rate in subsequent pregnancies (6% to 17% after one episode, up to 25% after two episodes).
- The increased cesarean rate over the past few decades has been associated with an increased diagnosis of placental implantation disorders—an important cause of vaginal bleeding in pregnancy.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Bleeding: Ranges from scant to life-threatening with hemodynamic instability
- Color: Brown to bright red
- Can be painless or painful (cramps, back pain, severe abdominal pain)
- Fetal compromise: Ranges from none to fetal demise

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any gestational age:
  1. Cervical lesions: Polyps, decidual reaction, neoplasia
  2. Vaginal trauma
  3. Cervicitis/vulvovaginitis
  4. Postcoital trauma
  5. Bleeding dyscrasias
- Gestation <20 wk:
  1. Implantation bleeding
  2. Spontaneous abortion
  3. Presence of intrauterine device
  4. Ectopic pregnancy (including cesarean scar and cervical or abdominal pregnancy)
  5. Molar pregnancy
  6. Low-lying placenta/placenta previa
  7. hCG-secreting tumors, including gestational trophoblastic neoplasia or gestational choriocarcinoma (incidence is 1 in 1500 to 20,000 pregnancies)
- Gestation >20 wk:
  1. Molar pregnancy
  2. Placental disorders (low-lying placenta, placenta previa, placenta accreta spectrum)
  3. Placental abruption
  4. Vasa previa
  5. Marginal separation of the placenta
  6. Preterm labor
  7. Bloody show at term
  8. Uterine rupture
  9. Postpartum hemorrhage related to retroplacental myomas
  10. Rare etiologies such as uterine artery aneurysm/pseudoaneurysm or uterine arteriovenous malformations (AVM). AVMs may be diagnosed following persistent vaginal bleeding after delivery or other uterine procedures

WORKUP

- Gestation <20 wk
  1. Pelvic examination with vaginal/cervical cultures if appropriate
  2. Laparoscopy (if indicated)
  3. Laparotomy (rarely required)
  4. Ultrasound to verify viable intrauterine pregnancy when β-hCG levels achieve threshold values (≥1500 mIU/ml for transvaginal sonography). If viable intrauterine pregnancy, evaluate pregnancy and uterine cavity including placenta and placental location
- Gestation >20 wk:
  1. Before pelvic examination, ultrasound for placental location, placental cord insertion, and placental evaluation
  2. If placenta previa or low-lying placenta, no bimanual examination
  3. If viable fetus, evaluation of fetal well-being as appropriate based on gestational age
  4. If suspected preterm labor, evaluate as clinically appropriate

LABORATORY TESTS

- Urine pregnancy test: If positive, get quantitative serum beta human chorionic gonadotropin (β-hCG). The following are typical although not entirely exclusive patterns:
  1. Early pregnancy: Follow serially every 48 hr
  2. Normal pregnancy: β-hCG doubles approximately every 48 hr
  3. Spontaneous abortion: β-hCG level will fall
  4. Ectopic pregnancy: β-hCG level will rise inappropriately (less than expected; threshold increase over 48 hr should be ≥66%)
  5. Molar pregnancy: β-hCG level is higher than expected for gestational age
- CBC
- Blood type and screen (Rh-negative patients need RhoGAM)
- Coagulation profile (particularly if moderate to heavy bleeding)
- Cervical/vaginal cultures, wet mount
- Pap smear for cervical malignancy; caution with biopsy as cervical biopsy sites in pregnancy can bleed extensively

IMAGING STUDIES

Ultrasound:

- 5 to 6 wk: Gestational sac (transvaginally); β-hCG >1500 mIU/ml is discriminatory level for visualization of a singleton gestation
- 6 to 7 wk: Fetal cardiac activity
- Molar pregnancy: Characteristic cluster of placental cysts
- Evaluate for evidence of subchorionic/submembranous hemorrhage or placenta accreta spectrum
- Location of placenta and placental cord insertion (particularly if >20 wk)
- Degree of placental separation: Difficult to assess

TREATMENT

NONPHARMACOLOGIC THERAPY

- Pelvic rest: No coitus, douching, or tampons
- Counseling: Genetic, bereavement (if indicated)
- For viable fetuses, ultrasound assessment of fetal growth and assessment of fetal well-being via external fetal monitoring as clinically appropriate
- Bed rest, if >20 wk (Recent studies show limited to no benefit of bed rest and possible increased medical and psychological risk to patients on activity restriction.)

ACUTE GENERAL Rx

- Hemodynamic stabilization with intravenous fluid administration and transfusion of blood products as clinically indicated
- Emergency dilation and curettage, laparoscopy, laparotomy, or cesarean delivery as necessary

REFERRAL

- If patient is unstable and needs emergency OB/GYN management and/or surgery
- If patient has suspected ectopic or molar pregnancy as immediate surgical treatment or medical intervention is indicated

- Perinatal consultation for high-risk pregnancies (placental implantation disorders, cesarean scar or abdominal pregnancy, placental abruption, vasa previa)
- Gynecologic oncology consultation if cervical carcinoma or hCG secreting tumor is suspected

BASIC INFORMATION

DEFINITION

Vaginal cancer is an abnormal proliferation of vaginal epithelium demonstrating malignant cells below the basement membrane.

SYNONYMS

Squamous cell carcinoma of the vagina
Adenocarcinoma of the vagina
Melanoma of the vagina
Sarcoma of the vagina
Endodermal sinus tumor
Vaginal malignancy

ICD-10CM CODE
C52 Malignant neoplasm of vagina

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: There were an estimated 5170 new cases in 2018 and an estimated 910 deaths.
PREVALENCE: Vaginal cancer is the second rarest gynecologic cancer. It comprises 3% of malignancies of the female genital tract. It is more prevalent in women infected with HPV.
MEAN AGE AT DIAGNOSIS: This is predominantly a disease of menopause. The mean age at diagnosis is 65.7 +/-14.3 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The signs and symptoms of invasive vaginal cancer (Fig. E1) are similar to those of cervical cancer. Majority of cases are asymptomatic.
- Postmenopausal vaginal bleeding and/or vaginal discharge are the most common symptoms.
- May also present as pelvic pain or pressure, dyspareunia, dysuria, malodor, or postcoital bleeding.
- May present as a vaginal lesion or abnormal Pap test.

ETIOLOGY

- The exact etiology is unknown.
- Approximately 80% to 90% of primary vaginal cancers are squamous cell carcinomas and 4% to 10% are adenocarcinomas.
- Most vaginal cancers are related to infection with HPV. It has been found in 65% of samples of invasive vaginal cancer and 93% of high-grade dysplastic vaginal lesions. Cervical cancers have similar risk factors. Patients with cervical cancer have an increased risk of vaginal carcinoma.
- Vaginal intraepithelial neoplasia (VaIN) is believed to be a precursor for squamous cell carcinoma of the vagina.
- HIV, smoking, and immunosuppression are risk factors. Prior pelvic radiation may be a risk factor.
- Clear-cell adenocarcinoma may be related to in utero diethylstilbestrol exposure (DES). Treatment of pregnant women with DES ended in the early 1970s, and it is anticipated that this spike in clear cell tumors will abate in the future.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Extension from another primary carcinoma is more common than primary vaginal cancer
- Vaginitis (atrophic or infectious)
- Vaginal mass: Polyp, endometriosis

WORKUP

- Diagnosis is made histologically by biopsy.
- Colposcopy and biopsy should follow suspicious Pap test.
- Cystoscopy, proctosigmoidoscopy, chest radiography, IV urography, and barium enema may be used for clinical staging.
- CT scan (Fig. E2), FDG, PET scan, and MRI are used to evaluate spread.
- Vaginal cancer staging is summarized in Table E1.

IMAGING STUDIES

- Chest radiography, IV urography, and barium enema are used for staging.
- CT scan and MRI are good for assessing tumor spread and planning radiation therapy.
- PET scan may have higher sensitivity in detecting primary spread and abnormal lymph nodes compared to CT scan.

TREATMENT

- Radiation therapy is the mainstay of treatment.
- Stage I tumors that are small and confined to the posterior, upper third of the vagina may be treated with radical surgery.
- Other stages require a whole-pelvis, interstitial, and/or intracavitary radiation therapy.
- Chemotherapy is used in conjunction with radiotherapy in select cases.
- Table E2 summarizes management of clear cell adenocarcinoma of the cervix and vagina.

DISPOSITION

5-yr survival ranges from 85% for stage I to 13% for stage IV vaginal squamous cell carcinoma.

REFERRAL

Vaginal cancer should be managed by a gynecologic oncologist and radiation oncologist.

TABLE E2 Suggested Management of Clear Cell Adenocarcinoma of the Cervix and Vagina

Stage	Surgery	Radiation
Cervix		
I_b	Radical hysterectomy with clear vaginal margins and bilateral pelvic lymphadenectomy	5000 cGy of the whole pelvis in patients with positive pelvic nodes
II_a	Radical hysterectomy with bilateral pelvic lymphadenectomy and upper vaginectomy	5000 cGy of the whole pelvis in patients with positive pelvic nodes
II_b	Consider exenteration for radiation failures	5000 cGy of the whole pelvis, tandem, and ovoids
III_a and III_b	Consider exenteration for radiation failures	6000 cGy of the whole pelvis, tandem, and ovoids
IV	Individualize	
Vagina		
I (upper third of vagina)	Radical hysterectomy with bilateral pelvic lymphadenectomy and upper vaginectomy	5000 cGy of the whole pelvis in patients with positive nodes
I (lower two-thirds of vagina)	Radical hysterectomy with bilateral pelvic lymphadenectomy and total vaginectomy with vaginal reconstruction	5000 cGy of the whole pelvis, vaginal application, or interstitial implant
II	Consider exenteration for radiation failures	5000 cGy of the whole pelvis, interstitial implant
III	Consider exenteration for radiation failures	6000 cGy of the whole pelvis, interstitial implant
IV	Individualize

BASIC INFORMATION

DEFINITION

Vaginal fistula is an abnormal passageway between the vagina and another epithelialized surface (Fig. E1).

SYNONYM

Vaginal sinus

ICD-10CM CODES

N82.0 Vesicovaginal fistula
N82.2 Fistula of vagina to small intestine
N82.3 Fistula of vagina to large intestine
N82.9 Female genital tract fistula, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: After benign hysterectomy: <1% (0.08% to 0.26%); after radical hysterectomy: 1% to 4%. Incidence is difficult to estimate in developing countries because of lack of medical care and medical follow-up after obstetric care.
PREVALENCE: Rare in the developed world from obstetric complications, but in developing countries, the best estimate of prevalence is as high as 124 in 100,000.
RISK FACTORS: In developing countries:

- Obstetric trauma
- Prolonged, protracted labor
- Cephalopelvic disproportion causing ischemia and necrosis of the tissue between the fetal head and maternal pubic bone

In developed countries:

- Hysterectomy, especially with the following:
  1. Extensive bladder dissection
  2. Iatrogenic injury of the bowel or bladder
  3. Prolonged operating times
  4. Laparoscopic approach has the greatest risk, vaginal approach the lowest
  5. Large blood loss
  6. Large volume uterus
  7. Coexisting pelvic adhesions distorting the normal pelvic anatomy
- Obstetric trauma:
  1. Rectovaginal fistulas are primarily related to severe vaginal lacerations. Risk factors for such include:
     a. Primiparity
     b. Midline episiotomies
     c. Increasing birth weights
     d. Use of vaginal forceps
  2. Bladder injury related to uterine rupture
- Invasive cancer
- Pelvic radiation, directly proportional to dosimetry:
  1. Also as a result of tumor necrosis after therapy
- Chronic inflammatory disease:
  1. Crohn disease
  2. Diverticulitis
- Pelvic infection:
  1. Tuberculosis
  2. Syphilis
  3. Lymphogranuloma venereum
- Trauma
- Previous pelvic surgery
- Diabetes mellitus
- Age >50, likely as a result of poor tissue quality from menopausal estrogen deficiency, although some studies have refuted this
- Tobacco usage
- Foreign bodies:
  1. Sub urethral slings for stress urinary incontinence have increased the incidence of urethrovaginal fistula
  2. Prolonged pressure between the fetal head and the maternal pubic bone, causing tissue necrosis
- Gynecologic:
  1. Extensive dissection about the urinary tract, including unidentified injury
  2. Poor-quality tissue with prolonged healing as a result of estrogen deficiency, infection, malignancy, or prior radiation therapy

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Flatus, stool, or urine per vagina
- Frequent urinary tract infections
- Urinary odor, hematuria
- Mucopurulent malodorous discharge per vagina
- Dyspareunia
- Perineal pain, perineal dermatitis
- Recurrent vaginal infections

ETIOLOGY (BOX E1)

- Obstetric:
  1. Incompletely repaired or unidentified vaginal lacerations

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rectal or urinary incontinence
- Pelvic inflammatory disease
- Vaginal infection
- Vaginal fistula:
  1. Vesicovaginal
  2. Urethrovaginal
  3. Ureterovaginal
  4. Rectovaginal
- Urinary tract infection

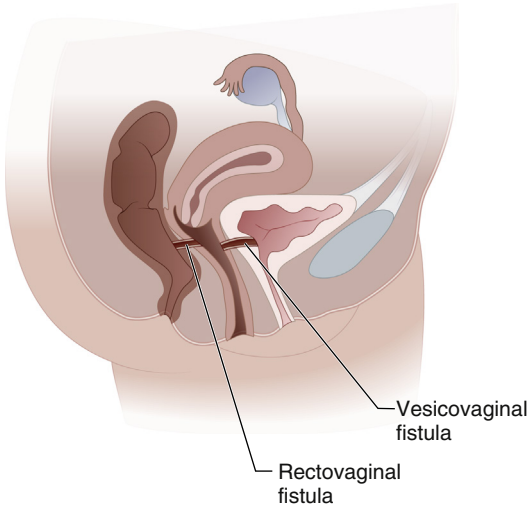

FIG. E1 The two most common types of vaginal fistulas are vesicovaginal and rectovaginal. (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, Saunders.)

BOX E1 Etiology of Vesicovaginal Fistula

Traumatic
  Postsurgical
    - Abdominal hysterectomy
    - Vaginal hysterectomy
    - Anti-incontinence surgery
    - Anterior vaginal wall prolapse surgery (e.g., colporrhaphy)
    - Vaginal biopsy
    - Bladder biopsy, endoscopic resection, laser therapy
    - Other pelvic surgery (e.g., vascular, rectal)
  External trauma (e.g., penetrating, pelvic fracture, sexual)
Radiation therapy
Advanced pelvic malignancy
Infectious or inflammatory cause
Foreign body
Obstetric
  Obstructed labor
  Forceps laceration
  Uterine rupture
  Cesarean section injury to bladder
Congenital

From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.

WORKUP

- Thorough history and physical exam, specifically, questioning about Crohn disease symptomology; constitutional symptoms such as weight loss and fatigue, with malignancy in mind. An algorithm for the diagnosis of vesicovaginal fistulas is illustrated in Fig. E2
- Obtaining of past medical records specific to obstetric and surgical procedures
- Evaluation of patient's rectal and urinary continence
- Physical exam, looking for extraintestinal signs consistent with Crohn disease; lymphadenopathy; inspection of perineum and perianal area for evidence of abscess, obvious fistula, or scarring; pooling of urine; pelvic exam including lighted speculum exam for any vulvar, vaginal, or cervical anomaly, excluding pelvic inflammatory disease
- For rectovaginal fistulas: Can use gel mixed with methylene blue massaged into the rectal tissues; if visualized vaginally can aid in localizing fistulous tract
- For vesicovaginal fistulas: Bladder backfill. Administration of dyed sterile fluid (indigo carmine, methylene blue, sterile milk) into the bladder through a catheter. If the dye is seen vaginally, it is diagnostic of vesicovaginal fistula
- For ureterovaginal fistula: Double dye tampon test. Oral Pyridium with administration of blue dye into the bladder. If orange dye is present, indicates a ureterovaginal fistula. If blue dye is present, indicates vesicovaginal fistula
- Biopsy of fistula tract

LABORATORY TESTS

- Urinalysis
- Urine culture
- Complete blood count
- Wet prep
- Gonococcal and chlamydial testing

IMAGING STUDIES

- Proctoscopy for suspected rectovaginal fistula
- Vaginogram (Figs. E3 and E4)
- Cystoscopy
- CT of the abdomen and pelvis to exclude malignancy (especially in women with no history of obstetric trauma, previous fistula, inflammatory bowel disease, or known pelvic malignancy) (Fig. E3)
- Endoanal ultrasound, with or without hydrogen peroxide contrast injected into the suspected fistula tract
- Magnetic resonance imaging
- Intravenous urogram
- Retrograde ureteropyelography

Rx TREATMENT (FIG. E5)

NONPHARMACOLOGIC THERAPY

- Tension-free surgical repair, with multiple documented approaches (Table E1):
  1. Transvaginal
  2. Perineal
  3. Abdominal
  4. Laparoscopic
  5. Robot assisted
  6. Transrectal
  7. Transanal endoscopy
- If vesicovaginal fistula is small (<1 cm) and identified early:
  1. Prolonged urinary catheter placement, greater than 3 weeks

ACUTE GENERAL Rx

- Treatment of urinary or vaginal infection
- Estrogen replacement therapy, local vs. systemic if no contraindications
- Surgical repair of fistula with subsequent pelvic rest for 4 to 6 wk
- Minimizing Valsalva maneuvers
- Fig. E6 illustrates a treatment algorithm for primary and recurrent rectovaginal fistulas

CHRONIC Rx

If initial surgical management fails, repeat operations tailored to the cause of the fistula would be indicated, such as advancement flaps, sphincteroplasty, coloanal anastomosis (for rectovaginal fistula), gracilis flap. A 10-yr retrospective cohort study from the English National Health Service inpatient database showed that 11.9% of patients required repeat operations.

DISPOSITION

Cure rates after surgical repair vary in the literature, especially with the type of fistula repaired. With early intervention, estimated cure rates are between 84% and 100% in developed countries.

REFERRAL

If there is concern for vaginal fistula, the patient should be managed by a surgeon familiar with fistula surgery for repair and follow-up. Consider consulting with a urologist, colorectal surgeon, gynecologic oncologist, or urogynecologist.

PEARLS & CONSIDERATIONS

PREVENTION

- Prompt repair of obstetric lacerations.
- Screen patients most at risk before surgery.
- Avoid urologic complications in surgery (e.g., injury to bladder or ureters).
- Perform cystoscopy with complicated hysterectomy dissections to identify defects immediately.

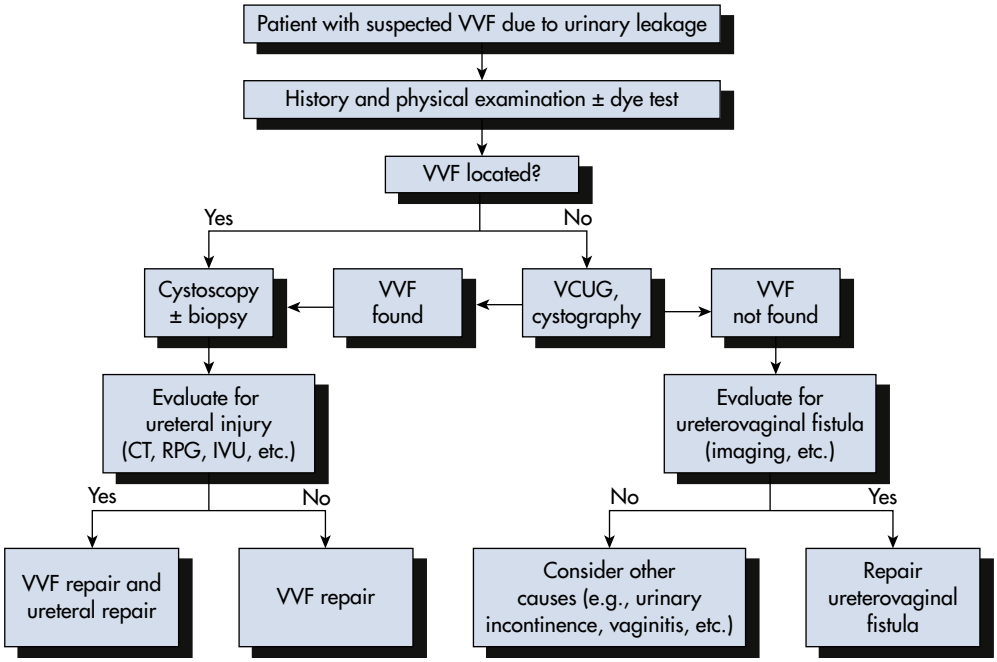

FIG. E2 Algorithm for the diagnosis of vesicovaginal fistula *(VVF).* *CT,* Computed tomography; *IVU,* intravenous urography; *RPG,* retrograde pyelography; *VCUG,* voiding cystourethrogram. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

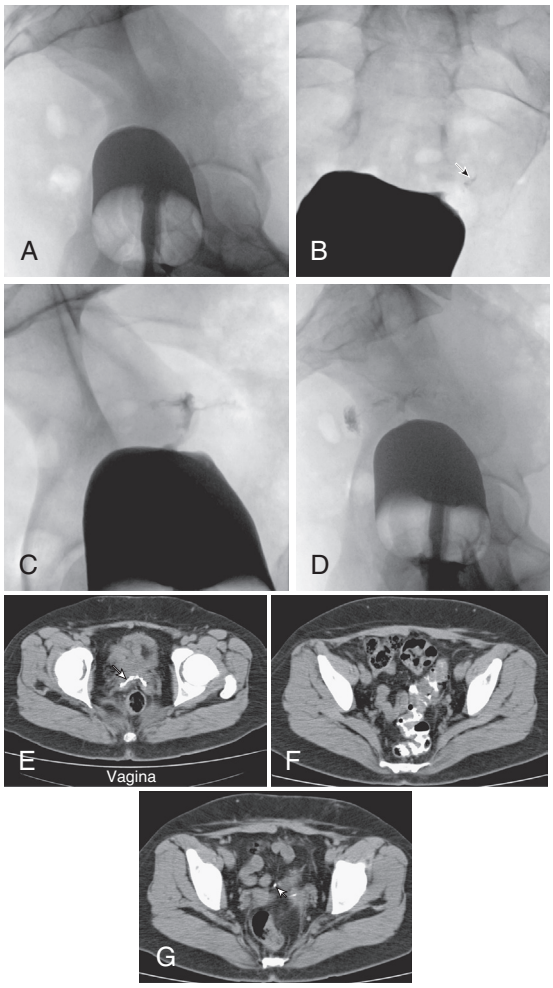

FIG. E3 A 44-year-old woman with gas and stool per vaginam 1 year after hysterectomy. Vaginal fistula was treated medically. **A,** Vaginogram, patient in left lateral position. **B,** Vaginogram, patient supine. The left apical vaginal fistula has just started to fill with contrast agent *(arrow).* **C,** Contrast agent is extending horizontally, likely in a loop of bowel. **D,** Vaginogram, patient in left lateral position, demonstrates small fistula to a loop of bowel, likely the rectosigmoid colon based on its relationship to the sacrum. **E,** Unenhanced computed tomographic (CT) scan of the pelvis immediately after the vaginogram demonstrates residual contrast agent in the vagina *(arrow).* **F,** CT scan confirms contrast agent from the vagina in the rectosigmoid colon. **G,** CT scan demonstrates 3 mm diameter short fistula to the rectosigmoid *(arrow).* (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, Saunders.)

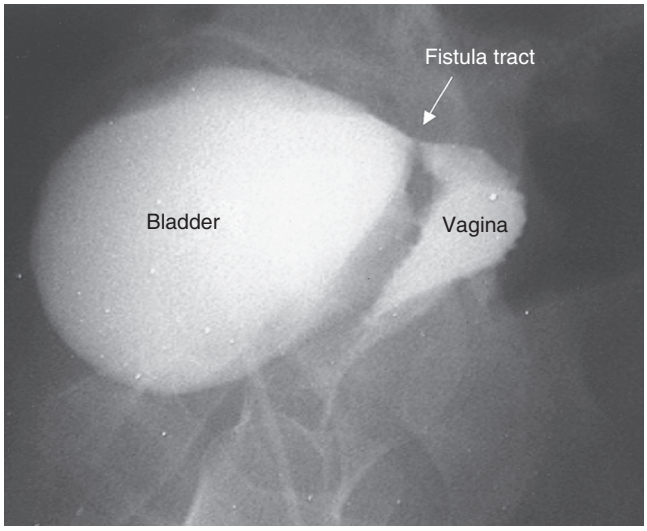

FIG. E4 Lateral image during cystography demonstrates the vesicovaginal fistula tract. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

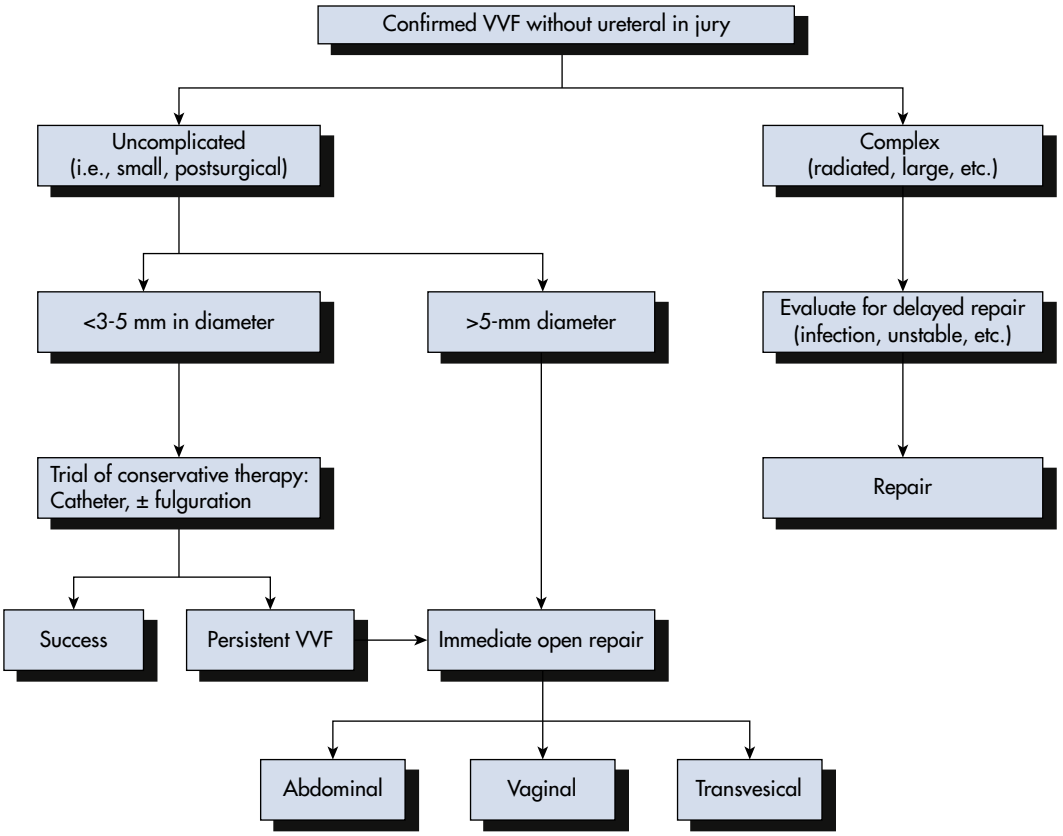

FIG. E5 Algorithm for management of vesicovaginal fistula *(VVF).* (From Wein AJ et al*: Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

TABLE E1 Abdominal versus Transvaginal Repair of Vesicovaginal Fistula

	Abdominal	Transvaginal
Incision	**Abdominal incision**	Vaginal incision(s) can be done immediately in the absence of infection or other complications.
Timing of repair (elapsed time from fistula creation)	Often delayed 3-6 months.	
Exposure	Fistula located low on the trigone or near the bladder neck may be difficult to expose transabdominally.	Fistula located high at the vaginal cuff may be difficult to expose transvaginally.
Location of ureters relative to fistula tract	Fistula located near ureteric orifice may necessitate reimplantation.	Reimplantation may not be necessary even if fistula tract is located near ureteric orifice.
Sexual function	No change in vaginal depth.	Risk of vaginal shortening (e.g., Latzko technique).
Use of adjunctive flaps	Omentum, peritoneal flap, rectus abdominis flap.	Labial fat pad (Martius fat pad), peritoneal flap, gluteal skin, or gracilis myocutaneous flap.
Relative indications	Large fistulae, location high in a deep narrow vagina, radiation fistulae, failed transvaginal approach, small-capacity bladder requiring augmentation, need for ureteral reimplantation, inability to place patient in the lithotomy position.	Uncomplicated fistulae, low fistulae.

From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.

Vaginitis, Estrogen-Deficient

BASIC INFORMATION

DEFINITION

Estrogen-deficient vulvovaginitis is the irritation and/or inflammation of the vulva and vagina because of progressive thinning and atrophic changes secondary to estrogen deficiency.

SYNONYMS

Atrophic vaginitis
Vulvovaginal atrophy
Genitourinary syndrome of menopause

ICD-10CM CODE
N95.2 Postmenopausal atrophic vaginitis

EPIDEMIOLOGY & DEMOGRAPHICS

- Postmenopausal women (average age 51 yr)
- Surgical menopause, ovarian failure or suppression, antiestrogenic medications, postpartum state
- Up to half of postmenopausal women are symptomatic, but a quarter of these will not seek treatment

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Thinning of pubic hair and epithelium, loss of vulvar architecture
- Decreased secretions from the vestibular glands with vaginal dryness
- Loss of elasticity and rugae
- Vulvar and vaginal itching
- Dyspareunia
- Dysuria and urinary frequency
- Vaginal spotting

ETIOLOGY

- Estrogen deficiency. Estrogen is essential to maintaining the urogenital environment. Postmenopausal thinning of the vaginal epithelium and increase in subepithelial connective tissue result in loss of rugal folds and elasticity. Reduced blood flow also contributes to a decline in vaginal secretions.
- Smoking and use of antiestrogen medications (e.g., aromatase inhibitors) increase the risk of vulvovaginal atrophy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious vulvovaginitis
- Squamous cell hyperplasia
- Lichen sclerosus
- Vulvar, vaginal, cervical, and endometrial malignancy
- Irritant contact dermatitis
- Vulvodynia

WORKUP

- Pelvic examination
- Speculum examination
- Pap smear <65 yr of age
- Wet prep
- Possible ultrasound and/or endometrial biopsy if bleeding
- Possible vulvar or vaginal biopsy in the event of suspicious lesion

LABORATORY TESTS

Vaginal pH, culture or polymerase chain reaction for vaginal infections, urinalysis and culture if indicated, follicle-stimulating hormone and estradiol testing if in doubt of menopausal state

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of contact irritants such as scented soaps and feminine hygiene products
- Avoidance of synthetic undergarments, tight-fitting clothing
- Regular use of vaginal moisturizers (e.g., Replens) can decrease vaginal itching and irritation
- Use of water- or silicone-based personal lubricants (e.g., Astroglide) during intercourse is useful to reduce dyspareunia

GENERAL Rx

- Vaginal estrogen: Comes in cream, tablet inserts, and impregnated silastic ring. Tablets or cream can be used daily for the first 2 weeks, then 1 to 2× per week for maintenance therapy. Progesterone for endometrial protection is not required for vaginal estrogen.
- Systemic hormone replacement therapy (HRT): Utilize lowest effective dose. Estrogen use should be reviewed every 3 to 6 mo, with an attempt to taper or discontinue its use. Comes as a patch or pill. If uterus present, opposing progesterone therapy for protection of endometrial lining, either continuous low-dose pills, cyclic pills, or progesterone intrauterine device.
- Ospemifene: Selective estrogen receptor modulator, some systemic side effects (hot flashes, possible risk of venous thromboembolism).
- Other: Prasterone vaginal dehydroepiandrosterone is approved though less widely studied; vaginal laser therapy is being studied but is not approved for treatment.

DISPOSITION

The symptoms should be improved with the therapy. Caution for vaginal bleeding if uterus present.

REFERRAL

To obstetrician/gynecologist if vaginal bleeding, vaginal narrowing, or other visible changes in appearance or tissue architecture.

Hohenhaus MH: Vulvovaginal atrophy: a common and commonly overlooked problem, *Med Health R I* 94:138-140, 2011.

BASIC INFORMATION

DEFINITION

Inflammation of the vagina or vulva caused by a fungal infection.

SYNONYMS

Candidiasis, vulvovaginal
Monilial vulvovaginitis
Vulvovaginal candidiasis
VVC
Vulvovaginitis

ICD-10CM CODE
B37.3 Candidiasis of vulva and vagina

EPIDEMIOLOGY

- Fungal vaginitis is the second most common type of vaginitis.
- Ten percent of women have asymptomatic colonization of *Candida.*
- The lifetime incidence of fungal vaginitis is 75%.
- About 5% of episodes are recurring.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Intense vulvar and vaginal pruritus or burning
- Linear ulcers may be present on perineal skin (Fig. E1)
- External dysuria
- Dyspareunia edema and erythema, excoriations of skin of the labia majora due to scratching (Fig. E2)
- Thick, white discharge ("cottage cheese" discharge) (Fig. E3)
- Severe infections may present with cracks in the vaginal wall
- May be asymptomatic

ETIOLOGY

- There are at least 15 distinct species of *Candida.*
- *Candida albicans* is responsible for 80% to 92% of vaginal fungal infections.
- *Candida glabrata* is the most common of non-albican isolates that cause infection.
- In recurrent fungal vaginitis, *Candida glabrata, Candida parapsilosis, Candida tropicalis,* and *Candida Krusei* are the most common non-*albicans Candida* species that can induce vaginitis.

PREDISPOSING RISK FACTORS

- Diabetes mellitus with poor glycemic control
- Antibiotic use
- Immunosuppression
- Increased estrogen levels (oral contraceptive use, pregnancy, estrogen therapy)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial vaginosis
- *Trichomonas* vaginitis
- Atrophic vaginitis
- Herpes simplex infection
- Cervicitis
- Vulvar intraepithelial neoplasia
- Lichen planus, lichen sclerosus
- Foreign body
- Hypersensitivity, allergic, or chemical reactions

WORKUP

- History and physical examination
- Pelvic and speculum examination: Pseudohyphae or blastospores seen with 10% KOH preparation on microscopy (positive in 50% to 70% of individuals with yeast infection) (Fig. E4)
- Vaginal pH <4.5
- Perform vaginal cultures if the infection is recurrent

FIG. E1 Vulvovaginal candidiasis. There is a linear ulcer of the perineal skin. (From Bennett et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.)

FIG. E2 Vulvovaginal candidiasis There are excoriations of the skin of the labia majora due to scratching. (From Bennett et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.)

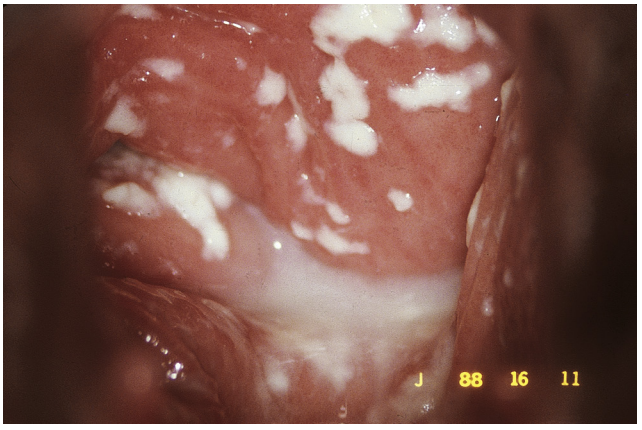

FIG. E3 Vulvovaginal candidiasis. There are adherent white patches with surrounding erythema on the cervical mucosa. (From Bennett et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.)

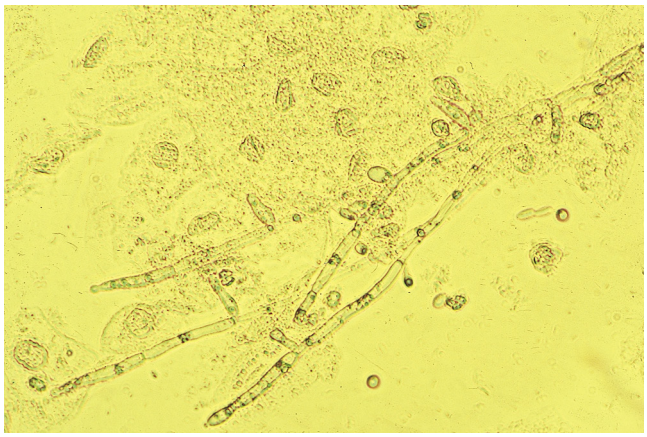

FIG. E4 Vulvovaginal candidiasis. Suspension of vaginal secretions in 0.9% NaCl. Mycelia can be seen. (From Bennett et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.)

- Classification of vulvovaginal candidiasis:
  1. Uncomplicated: Infrequent episodes (three or fewer/yr), mild to moderate symptoms, caused by *C. albicans*, nonpregnant patient and without medical complications.
  2. Complicated: Recurrent episodes (four or more/yr), severe symptoms, non-*albicans Candida*, poorly controlled diabetes, immunosuppression, severe medical illness, other vulvovaginal conditions and/or pregnancy.

Rx TREATMENT

PREVENTION

- Wear cotton underwear.
- Only take antibiotics when prescribed.

ACUTE GENERAL Rx

- Cure rate of the various azole derivatives is 85% to 90%; there is little evidence of superiority of one azole agent over another with similar efficacy when administered by either oral or vaginal route.
- For the treatment of acute, uncomplicated *Candida vulvovaginitis*, a single dose of fluconazole 150 mg PO is recommended.
- For severe infections, treatment with fluconazole 150 mg PO every 72 hr for two to three doses is recommended.
- Oral azoles may cause gastrointestinal side effects such as nausea, abdominal pain, headache, and liver function test elevations.
- The most common side effect of topical azoles is a local burning sensation or irritation.
- Alternatives:
  - Miconazole 200-mg suppository, one suppository ×3 days, 100 mg suppository ×7 days, 1200 mg suppository ×1 day, or 2% vaginal cream, one applicator (5 g) intravaginally ×7 days, or 4% vaginal cream, one applicator (5 g) intravaginally ×3 days.
  - Clotrimazole 1% vaginal cream (5 g) intravaginally qhs ×7 or 2% vaginal cream intravaginally (5 g) ×3 days.
  - Tioconazole 6.5% ointment (Monistat), one applicator intravaginally ×1.
- In pregnant patients, treat with topical clotrimazole or miconazole therapy for 7 days.

CHRONIC Rx (FOUR OR MORE SYMPTOMATIC EPISODES ANNUALLY)

- Resistance or recurrence:
  1. If recurrence is due to *C. albicans*: Induction therapy with oral fluconazole every 72 hours for a total of three doses or treat with 7 to 14 days of topical therapy or, then continue with fluconazole 150 mg PO weekly for 6 mo.
     a. If fluconazole not feasible, treat with topical azole or alternate oral azole 10 to 14 days then maintenance therapy for 6 mo.
  2. If recurrence is due to *C. glabrata* or *C. krusei*, there is a reduced susceptibility to fluconazole.
     a. *C. glabrata:*
        - Boric acid 600-mg capsule intravaginally daily ×14 days
        - Nystatin 100,000 units vaginal tablet daily ×14 days
        - For failure, 17% topical flucytosine cream, 5 g nightly ×14 days
     b. *C. krusei:*
        - Topical nonfluconazole (clotrimazole, miconazole, terconazole) regimen for 7 to 14 days

PEARLS & CONSIDERATIONS

COMMENTS

- Treatment indicated for symptom relief.
- No evidence that treating a woman's male sexual partner significantly improves woman's infection or reduces her rate of relapse.
- Various oral and topical preparations available, and patient preference, cost, and contraindications should be considered when prescribing.
- Vaginal creams and suppository regimens may weaken latex condoms and diaphragms.

BASIC INFORMATION

DEFINITION

Prepubescent vulvovaginitis is an inflammatory condition of the vulva and vagina.

SYNONYM

Vulvovaginitis

ICD-10CM CODES
N76.0 Acute vaginitis
N76.1 Subacute and chronic vaginitis

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common gynecologic problem of premenarchal girls.
- Prepubertal girls are susceptible to irritation and trauma because of the absence of protective hair and labial fat pads, as well as a lack of estrogenization leading to atrophic vaginal mucosa.
- Symptoms of vulvovaginitis and introital irritation and discharge account for 80% to 90% of gynecologic visits.
- Nonspecific etiology in approximately 75% of children with vulvovaginitis.
- Majority of vulvovaginitis in girls involves a primary irritation of the vulva with secondary involvement of the lower third of the vagina.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Vulvar pain, dysuria, pruritus.
- Discharge is not a primary symptom but can occur.
- If present, vaginal discharge may be foul smelling or bloody.

ETIOLOGY

- Most commonly attributed to poor hygiene or nonspecific irritants. Etiologic factors in premenarcheal vulvovaginitis are summarized in Box 1.
- Hypoestrogenic state increases risk of infection or irritation due to:
  1. Higher vaginal pH (more hospitable to infectious agents)
  2. Underdeveloped labia minora and lack of significant adipose and hair of labia majora (less intrinsic protection of the vagina from trauma, irritants, infectious agents)
- Infections:
  1. Bacterial: Often respiratory or enteric organisms
  2. Protozoal/parasitic
  3. Mycotic
  4. Viral
- Endocrine disorders
- Labial adhesions
- Skin disorders
- Sexual abuse
- Allergic substance
- Trauma
- Foreign body
- Masturbation
- Constipation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Physiologic leukorrhea
- Foreign body
- Bacterial vaginosis
- Fungal vulvovaginitis
- Precocious puberty
- Sexual abuse and possibly an associated sexually transmitted infection such as gonorrhea, *Chlamydia*, or *Trichomonas*
- Pinworms

WORKUP

- History regarding symptoms, hygiene practices, exposures to known irritants
- Examination, including Tanner staging, pelvic/genital examination; possibly speculum examination
  - May need rectal examination.
  - Knee-chest position for examination may be easier for the child to tolerate. May need to consider exam under anesthesia for more thorough evaluation if necessary.
- KOH and normal saline preparation of discharge
- Vaginoscopy if considering a foreign body

LABORATORY TESTS

- Urinalysis to rule out urinary tract infection and diabetes
- Cultures including sexually transmitted diseases

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoid tight clothing
- Appropriate hygiene education
- Avoid chemical irritants
- If foreign body, removal via irrigation or exam under anesthesia
- If vulva is irritated, can use a topical over-the-counter emollient
- Reassurance

ACUTE GENERAL Rx

- *Streptococcal* and *staphylococcal* spp, *Haemophilus influenzae*: For children <20 kg, ampicillin 25 mg/kg q6h or amoxicillin 20 mg/kg q12h for 5 to 10 days; for children >20 kg, ampicillin 500 mg q6h or amoxicillin 20 mg/kg q12h for 5 to 10 days
- *Escherichia coli*: Azithromycin PO, 10 mg/kg on day 1 and then 5 mg/kg for 4 days.
- *Proteus vulgaris*: TMP-SMX 5 mg/kg q12h for 5 to 10 days
- *Chlamydia trachomatis*: For children <45 kg, treat with erythromycin base or ethylsuccinate 50 mg/kg/day PO qid ×14 days. For children ≥45 kg but younger than 8 yr, treat with azithromycin 1g PO single dose. If older than 8 yr, also can consider doxycycline 100 mg PO bid for 7 days
- *Neisseria gonorrhoeae*: For children ≤45 kg, treat with ceftriaxone 25 to 50 mg/kg IV or IM in a single dose, not to exceed 125 mg IM. Children >45 kg should be treated with ceftriaxone 250 mg IM plus azithromycin 1 g PO once
- *Trichomonas*: Metronidazole 15 mg/kg/day (divided into two doses per day) ×7 days or a single dose of 40 mg/kg.
- Pinworms: Mebendazole 100-mg chewable tablet, repeat in 2 to 3 wk
- Labial agglutination: Spontaneous resolution or topical estrogen cream for 7 to 10 days. High degree of efficacy with topical estrogen

CHRONIC Rx

See "Referral."

DISPOSITION

Further education:
- Discuss appropriate hygiene.
- If sexually active, discuss pregnancy prevention and safe sexual practices. Have a high suspicion of sexual abuse and report to child protective services with any concerns for abuse.

REFERRAL

- To obstetrician/gynecologist, preferably a physician with specialized training in pediatric and adolescent gynecology if available
- To pediatrician

BOX 1 Etiologic Factors in Premenarcheal Vulvovaginitis

Bacterial Infections
Nonspecific mixed infections secondary to:
Poor perineal hygiene
Foreign body in vagina
Respiratory tract infections
Skin infections (impetigo)
Urinary tract infection
Specific nonvenereal infection:
Hemolytic streptococci (groups A, B, F)
Escherichia coli
Shigella flexneri, Shigella sonnei
Neisseria meningitidis, Neisseria sicca
Haemophilus influenzae type b, nontypeable strains
Streptococcus pneumoniae
Corynebacterium diphtheriae
Yersinia enterocolitica
Mycobacterium tuberculosis
Moraxella (Branhamella) catarrhalis
Staphylococcus aureus
Specific venereal infections:
Neisseria gonorrhoeae
Treponema pallidum
Chlamydia trachomatis
Chancroid *(Haemophilus ducreyi)*
Granuloma inguinale
Bacterial vaginosis:
Gardnerella vaginalis
Mobiluncus species
Fungal infections
Candida albicans
Other yeasts
Dermatophytes
Protozoan and parasitic infections
Trichomoniasis
Amebiasis
Enterobius vermicularis
Hirudiniasis
Schistosomiasis
Other parasitic infections (ascariasis, trichuriasis)
Viral infections
Venereal:
Herpes simplex
Condyloma acuminatum (papillomavirus)
Molluscum contagiosum
Involvement as part of systemic infection:
Measles
Varicella
Mononucleosis (Epstein-Barr virus)
Coxsackievirus
Smallpox
Infestations
Pediculosis
Scabies
Contact irritation or allergic reactions
Bubble bath preparations
Hair shampoos
Vulvar deodorant sprays
Soaps, laundry detergents
Other medications
Vulvar or perineal skin diseases
Local:
Seborrhea
Lichen sclerosus et atrophicus
Lichen planus
Lichen simplex chronicus
Premalignant leukoplakia
Erythrasma (*Corynebacterium minutissimum*)
Bartholinitis
Skenitis
Involvement as part of a systemic disorder:
Psoriasis
Bullous pemphigoid
Atopic dermatitis
Drug eruption
Generalized pruritus with excoriation
Chronic liver disease
Chronic renal disease
Metabolic errors
Psychosomatic
Crohn disease
Sjögren syndrome
Henoch-Schönlein purpura
Histiocytosis
Kawasaki disease
Stevens-Johnson syndrome
Typhoid
Zinc deficiency
Physical factors
Sand (sandbox)
Chemical or thermal trauma
Physical trauma (accidents, abuse, masturbation)
Nylon, rayon underclothing
Tight garments (maceration in warm climates)
Anatomic abnormalities:
Neoplasms (sarcoma botryoides)
Polyps
Labial agglutination, adhesion
Prolapsed urethra
Ectopic ureter
Rectal fistula
Draining pelvic abscess via fistula

BASIC INFORMATION

DEFINITION

Trichomonas vulvovaginitis is the inflammation of vulva and vagina caused by *Trichomonas vaginalis*.

SYNONYMS

Trichomonas vaginalis
Trichomoniasis
TV

ICD-10CM CODE
A59.01 Trichomonal vulvovaginitis

EPIDEMIOLOGY & DEMOGRAPHICS

- Acquired through sexual contact
- Diagnosed in:
  1. 50% to 75% of sex workers
  2. 5% to 15% of women visiting gynecology clinics
  3. 7% to 32% of women in sexually transmitted disease (STD) clinics
  4. 5% of women in family planning clinics
  5. 8% to 13% of black women, 0.8% to 1.8% of non-Hispanic white women
  6. More than 11% of women ≥40 yr old
- Most prevalent nonviral sexually transmitted infection in the U.S.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

These symptoms and physical findings may or may not be present depending on the case:

- Yellow-green, malodorous vaginal discharge
- Vaginal and/or vulvar pruritus
- Dysuria
- Dyspareunia
- Intense erythema of the vaginal mucosa
- Cervical petechiae ("strawberry cervix")
- Infected men may have symptoms of urethritis, epididymitis, or prostatitis
- Asymptomatic in ~50% of women and 90% of men

ETIOLOGY

Single-cell protozoan *Trichomonas vaginalis*

RISK FACTORS

- Multiple sexual partners
- History of previous STDs
- HIV infection

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (TABLE E1)

- Bacterial vaginosis
- Fungal vulvovaginitis
- Atrophic vulvovaginitis
- Vaginal or cervical infection with other sexually transmitted infections such as gonorrhea or chlamydia

WORKUP

- Pelvic examination
- Speculum examination
- Evaluation for mobile trichomonads seen on normal saline preparation (Fig. E1): 30% to 70% sensitivity; sensitivity decreases if there is a delay in evaluating slides
- Assessment of vaginal pH: Trichomonas is associated with elevated pH (>5) of vaginal discharge
- Laboratory testing (see below)

LABORATORY TESTS

- Nucleic acid amplification tests (NAATs) have been developed that combine excellent performance characteristics (sensitivity and specificity >95%) with a more rapid turnaround time compared with culture. Thus, they are now considered better laboratory tests than culture. There are two commercially available NAATs in the U.S.:
  1. APTIMA assays (Hologic Gen-Probe, San Diego, CA)
  2. BD Probe Tec TV Q^X Amplified DNA Assay (Becton Dickinson, Franklin Lakes, NJ)
- Rapid tests are also available:
  1. The OSOM Trichomonas Rapid test (Sekisui Diagnostics, Framingham, MA) is an antigen detection test on vaginal secretions. It provides results in 10 min and can be done as a point-of-care test. It has a sensitivity of 82% to 95% and a specificity of 97% to 100%.
  2. The Affirm VP III (Becton Dickinson, Sparks, MD) is a DNA hybridization probe test; results are available within 45 min. Sensitivity is 63% and specificity >99%.
- Culture, when available, is considered the traditional gold standard laboratory test for diagnosis of trichomonas, with sensitivity 75% to 96% and specificity approaching 100%.

TREATMENT

NONPHARMACOLOGIC THERAPY

Condom use: The best way to prevent trichomoniasis is through consistent and correct use of condoms during all penile-vaginal sexual encounters

ACUTE GENERAL Rx

- Preferred initial treatment: Metronidazole 2 g PO × 1 *or* tinidazole single 2-g oral dose in both sexes. Treatment of the sexual partner is essential to prevent reinfection.
- Alternative regimen: Metronidazole 500 mg PO bid × 7 days.
- Alcohol consumption should be avoided during treatment with metronidazole (at least 24 hr after completion of therapy) and tinidazole (at least 72 hr after completion of therapy) to reduce possibility of disulfiram-like reaction.
- CDC recommends retesting sexually active women within 3 mo of treatment to assess for possible reinfection.

CHRONIC Rx

- For persistent infections, the CDC recommends first trying metronidazole 500 mg PO bid × 7 days.
- If treatment is still unsuccessful, proceed with metronidazole or tinidazole 2 g PO daily × 7 days.
- Allergy, intolerance, or adverse reactions: Alternatives to metronidazole or tinidazole are not recommended. Patients who are allergic to nitroimidazoles can be managed by desensitization.
- Pregnancy:
  1. Associated with adverse outcomes (i.e., premature rupture of membranes, preterm delivery), although it is unclear whether treatment decreases the incidence of these outcomes.
  2. Treat with metronidazole 2 g PO × 1 day; avoid tinidazole as there is little known about tinidazole in pregnancy.

DISPOSITION

- *Trichomonas* infection is considered an STD; therefore, treatment of the sexual partner is necessary.
- *T. vaginalis* infection is associated with two- to threefold increased risk for HIV acquisition.
- *T. vaginalis* infection in pregnancy is associated with premature rupture of membranes, preterm birth, and delivery of low birth weight infants.

REFERRAL

To obstetrician/gynecologist for recurrence and pregnancy

Vaginosis, Bacterial PTG

BASIC INFORMATION

DEFINITION

Bacterial vaginosis (BV) is a polymicrobial infection in which anaerobic bacteria overgrow and replace the normal hydrogen peroxide-producing lactobacilli, resulting in thin, gray, and malodorous vaginal discharge.

SYNONYMS

Bacterial vaginosis
BV
Nonspecific vaginitis
Gardnerella vaginalis vaginitis

ICD-10CM CODES

N76.0 Acute vaginitis
N77.1 Vaginitis, vulvitis and vulvovaginitis in diseases classified elsewhere

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common cause of vaginal discharge in women of reproductive age.
- Most common organisms include *Gardnerella vaginalis*, *Porphyrmonas* species, *Mycoplasma hominis, Bacteroides* species, *Peptostreptococcus* species, *Ureaplasma urealyticum, Fusobacterium* species, *Prevotella* species, and *Atopobium vaginae*, and other facultative anaerobes.
- Women with BV are at increased risk for acquiring other sexually transmitted diseases (STDs) such as HIV, *N. gonorrhoeae, C. trachomatis,* and HSV-2. BV may contribute to persistent HPV infection. Also associated with pelvic inflammatory disease (PID) and complications after gynecologic surgery. Preoperative evaluation and treatment before planned hysterectomy or abortion decreases the infection complication rate.
- May be associated with low birth weight, premature rupture of membranes (PROM), and prematurity.
- BV may recur in 30% within the first 3 months after treatment, which may be due to:
  1. Persistence of pathogenic bacteria
  2. Reinfection from exogenous sources including sexual partners
  3. Failure of the normal lactobacillus-dominant flora to reestablish
- Risk factors: Multiple female or male sexual partners, sexually transmitted infections, douching, tobacco use, lack of condom use, and lack of vaginal lactobacilli.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- 50% to 75% of patients are asymptomatic.
- A thin, dull, and gray homogeneous discharge (Fig. E1)
- Characterized by a "fishy" odor from the vagina
- Vaginal pH >4.5
- BV alone does not typically cause dysuria or dyspareunia, and presence may suggest concomitant infection with another pathogen
- Clue cells on microscopic examination (Fig. E2)

ETIOLOGY

- *Gardnerella vaginalis* detected in 40% to 50% of vaginal secretions.
- Increase in vaginal pH secondary to decrease in hydrogen peroxide producing lactobacilli allows predominance of anaerobes that produce amines.
- It is unclear how the vaginal floral imbalance occurs and the role sexual activity plays in the pathogenesis of BV.
- *G. vaginalis* may be important in epithelial biofilm formation.
- Ethnicity and age may contribute to the vaginal microbial environment.

DIAGNOSIS

WORKUP

At least three of the Amsel clinical diagnostic criteria:

- Sensitivity of 92% and specificity of 77%:
  1. Thin, gray, and homogeneous, malodorous discharge that adheres to the vaginal walls.
  2. Vaginal pH >4.5.
  3. Positive whiff-amine test:
     a. Conducted by placing wet mount specimen and adding 10% potassium hydroxide, which creates a fishy odor.
  4. More than 20% of the epithelial cells are clue cells on microscopy.
- Gram staining: Considered the gold-standard laboratory method to determine the concentration of lactobacilli and gram-negative and gram-positive bacteria.
- If microscopy is unavailable, other diagnostic tests include Affirm VPIII (Becton Dickinson, Sparks, MD), which is a DNA-hybridization probe test for high concentrations of *G. vaginalis*, and the OSOM BV Blue test (Sekisui Diagnostics, Framingham, MA), which detects vaginal fluid sialidase activity. A molecular test for the vaginal microbiome for BV, candidiasis, and trichomonas (BD MAX Vaginal Panel) has also shown promising results in early studies.
- Cultures are unnecessary.
- Pap smear is not a reliable test for BV.
- Rule out other causes such as vulvar diseases, STDs, and atrophic vaginitis.

TREATMENT

ACUTE GENERAL Rx

- Recommended regimens (similar efficacy):
  1. Metronidazole 500 mg PO bid for 7 days *or*
  2. Metronidazole 0.75% gel, one full applicator (5 gm) intravaginally daily for 5 days *or*
  3. Clindamycin 2% cream, one full applicator (5 gm) intravaginally at bedtime for 7 days
- Alternate regimens:
  1. Clindamycin 300 mg PO bid for 7 days or clindamycin 100 mg ovules intravaginally once at bedtime for 3 days. May be associated with antimicrobial resistance.
  2. Tinidazole 1g PO once daily for 5 days. Longer half-life than metronidazole (~12 to 14 hr vs. ~6 to 7 hr)
  3. Secnidazole 2g PO once. Longer half life than metronidazole (~17 hr vs. ~8 hr). Shown to be superior to placebo in phase 3 trial and at least as effective as metronidazole 500 mg PO bid in noninferiority trial. Single 1-g oral dose appears to be effective also. Single dose improves compliance, but more expensive than multidose metronidazole therapy.
- Disulfiram-type reactions may occur while taking oral or topical metronidazole and patients should be advised to avoid alcohol while undergoing treatment.
- Sexual partners: It is not necessary to treat male partners of affected females; however, females who partner with females need to be aware of the signs and symptoms of BV, and treatment is indicated in this population if symptoms occur.
- Follow-up visits after treatment and resolution of symptoms are unnecessary, but patients are advised to return if symptoms recur.
- Not enough evidence for or against probiotic use for treatment and prevention.
- Clindamycin cream may weaken latex condoms if used together. Avoid treatment of asymptomatic patients.
- Treatment in pregnancy:
  1. Symptomatic pregnant patients with BV should be treated to relieve bothersome symptoms.
  2. Insufficient evidence to recommend routine screening for BV in asymptomatic pregnant women at high or low risk of preterm delivery.
  3. Can use oral or topical therapy for symptomatic pregnant women with same regimen as nonpregnant women.
  4. There is no evidence that metronidazole or clindamycin have any teratogenic effect during pregnancy. Tinidazole should be avoided in pregnancy.
- Recurrent BV:
  1. Condom use may help reduce the risk of recurrence.
  2. Chronic suppressive therapy has been proven to reduce the development or recurrence of BV.

PEARLS & CONSIDERATIONS

- BV is the most common cause of vaginitis in reproductive women.
- BV has been associated with PID, postprocedural gynecologic complications, and other STDs. It is reasonable to treat asymptomatic women who are to undergo gynecologic surgery and screen for other STDs.
- ACOG, USPSTF, and CDC all agree to not routinely screen and treat all pregnant women with asymptomatic BV to prevent preterm birth.

BASIC INFORMATION

DEFINITION

Enterococci are gram-positive, facultative anaerobic organisms usually oval in shape and can be seen as single cells, pairs, or chains. Vancomycin-resistant *Enterococcus* (VRE) are enterococci that have become resistant to vancomycin and several antibiotics normally used to treat enterococcal infections.

SYNONYM

VRE

ICD-10CM CODE

Z16.39 Resistance to other specified antimicrobial drug

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: VRE may be associated with the use of specific classes of antibiotics.

PEAK INCIDENCE: VRE was first reported in Europe in 1986, and there has been a steady rise in the incidence of enterococcal strains resistant to vancomycin. In 2007, 80% of *E. faecium* isolates and 7% of *E. faecalis* isolates were resistant to vancomycin.

PREVALENCE: Eighty percent of *E. faecium* are VRE; 69% of *E. faecalis* are VRE.

RISK FACTORS:

- Prior antimicrobial therapy, especially vancomycin
- Prolonged hospitalization
- Chronic medical conditions, renal failure
- Invasive devices
- ICU stay
- Colonization: VRE colonize the gastrointestinal tract; can be found on skin or perirectal swab culture or stool culture

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients may be asymptomatic and have gastrointestinal colonization; it can be associated with diarrhea. In hospitalized patients, infection is associated with colonization and can cause wound infections, bacteremia, abscesses (intraabdominal), and, rarely, pneumonia, urinary tract infections, and endocarditis.

ETIOLOGY

- The Clinical and Laboratory Standards Institute uses the following MIC definitions for vancomycin susceptibility and resistance in enterococci:
  1. Vancomycin susceptible: ≤4 mcg/ml
  2. Vancomycin resistant: ≥32 mcg/ml
  3. Vancomycin intermediate: 8 to 16 mcg/ml (vancomycin not recommended)
- Enterococci are primarily found in the human digestive tract and female genital tract, where they make up a significant portion of the normal bacterial population in healthy people. Enterococci can cause urinary tract, wound, bloodstream, heart valve, and brain infections. In the great majority of cases, VRE infections occur in hospitalized patients who have compromised immune systems. Most cases of VRE are caused by the *E. faecium* strains that have acquired resistance when they came in contact with other bacteria and shared genetic information.
- VRE is most commonly transmitted from one patient to another by health care workers whose hands have become contaminated inadvertently with feces or fluids of a person carrying the organism. VRE are not airborne but can survive on surfaces for several weeks.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other bacterial pathogens in blood, wounds, or urine.
- Once colonized, increased incidence to become infected

LABORATORY TESTS

- VRE rectal culture
- VRE stool culture
- Blood, urine, and wound cultures

TREATMENT

- For rectal or stool colonization, therapy is not recommended.
- Therapy is complicated by the fact that strains exhibit inherent resistance to many commonly used antibiotics.
- More than 80% of vancomycin-resistant *E. faecium* strains are also resistant to ampicillin.
- In symptomatic patients, if VRE strains are known to be susceptible, potential therapeutic agents include:
  1. Linezolid: 600 mg IV or PO q12h
  2. Daptomycin: 4 mg/kg/day IV for nonbacteremia infections and 6 mg/kg/day IV for bacteremias
  3. Tigecycline: 100 mg IV load dose, then 50 mg IV q12h. Although not specifically FDA approved for VRE strains, it offers an option for patients intolerant to other agents
  4. Quinupristin-dalfopristin (Synercid) only effective for *E. faecium* strains with no activity for *E. faecalis* strains: 7.5 mg/kg q8 to 12h. Can cause severe myalgias and arthralgias and venous irritation that often requires use of a central line, which has limited the use of this antibiotic
  5. Salvage regimens for severe VRE infections include:
     a. Daptomycin plus gentamicin and/or ampicillin or ceftaroline
     b. Daptomycin plus tigecycline
  6. The Healthcare Infection Control Practices Advisory Committee recommends that three negative stool/rectal cultures be obtained at weekly intervals to remove a patient from contact precautions.

REFERRAL

To infectious disease specialist

PEARLS & CONSIDERATIONS

COMMENTS

- Patients who are colonized with VRE have about an 8% rate of developing a true VRE infection in hospital or after discharge. The rate is higher in immunocompromised and severely ill patients.
- Incidence increases with comorbidity and hospitalization.
- The number of patients already colonized with VRE in a defined geographic area (colonization pressure) is the most significant factor for predicting new acquisition of VRE.
- An association between VRE colonization and *Clostridium difficile* infection has been reported in patients with hematologic malignancies.

PREVENTION

- Hand hygiene: Most important and practical method of preventing spread in hospital environment. Soap and water (used as a 30-sec wash) and alcohol-based hand rubs are effective, as is chlorhexidine.
- Cohorting and isolation techniques: Use of private rooms and use of gowns and gloves has been shown to decrease the risk of spread of multidrug-resistant bacteria.
- Cleaning contaminated objects or surfaces with standard hospital disinfectants, antibiotic management (prudent vancomycin use), and surveillance also help prevent spread.

BASIC INFORMATION

DEFINITION

Varicella is a viral illness caused by varicella-zoster virus and characterized by the acute onset of a generalized vesicular rash and fever.

SYNONYM

Chickenpox

ICD-10CM CODES

B01.9	Varicella without complication
B01.8	Varicella with other complications
B01.0	Varicella meningitis
B01.11	Varicella encephalitis and encephalomyelitis
B01.12	Varicella myelitis
B01.2	Varicella pneumonia
B01.81	Varicella keratitis
B01.89	Other varicella complications
Z20.820	Contact with and (suspected) exposure to varicella

EPIDEMIOLOGY & DEMOGRAPHICS

- Varicella is extremely contagious. More than 90% of unvaccinated contacts become infected.
- The incubation period of chickenpox ranges from 9 to 21 days.
- The peak incidence is during the springtime.
- The predominant age is 5 to 10 yr.
- The infectious period begins 2 days before the onset of clinical symptoms and lasts until all of the lesions have crusted.
- Most patients will have lifelong immunity after an attack of chickenpox; protection from the virus after a varicella vaccine is approximately 6 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Findings vary with the clinical course. Initial symptoms consist of fever, chills, backache, generalized malaise, and headache.
- Symptoms are generally more severe in adults.
- Initial lesions generally occur on the trunk (centripetal distribution) and occasionally on the face; these lesions consist primarily of 3- to 4-mm red papules with an irregular outline and a clear vesicle (Fig. E1) on the surface (i.e., the appearance of dewdrops on a rose petal).
- Intense pruritus generally accompanies the initial stage.
- New lesion development generally ceases by the fourth day, with subsequent crusting by the sixth day.
- Lesions generally spread to the face and the extremities (i.e., centrifugal spread).
- Patients generally present with lesions that are in different stages at the same time.
- Crusts generally fall off within 5 to 14 days. Scarring may occur in association with secondary bacterial infections (Figs. E2 and E3).
- The fever is usually highest during the eruption of the vesicles; the patient's temperature generally returns to normal after the disappearance of vesicles.
- Skin lesions may become superinfected with *Streptococcus pyogenes* or *Staphylococcus aureus*.
- Signs of potential complications (e.g., bacterial skin infections, neurologic complications, pneumonia, hepatitis) may be present on physical examination.
- Mild constitutional symptoms (e.g., anorexia, myalgias, headaches, restlessness) may be present; these are most common among adults.
- Excoriations may be present if scratching is prominent.

ETIOLOGY

Varicella-zoster virus (VZV) is a human herpes virus III (HHV-3) that can manifest with either varicella or herpes zoster (i.e., shingles, which is a reactivation of varicella).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other viral infection
- Impetigo
- Scabies
- Drug rash
- Urticaria
- Dermatitis herpetiformis
- Smallpox

WORKUP

The diagnosis is usually made on the basis of the patient's history and clinical presentation.

LABORATORY TESTS

- Laboratory evaluation is generally not necessary.
- The CBC may reveal leukopenia and thrombocytopenia.
- Serum varicella titers (i.e., a significant rise in the serum varicella immunoglobulin G antibody level), skin biopsies, or Tzanck smears are used only when diagnosis is in question.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Use antipruritic lotions for symptomatic relief.
- Avoid scratching to prevent excoriations and superficial skin infections.
- Use a mild soap for bathing.
- Hands should be washed often.

ACUTE GENERAL Rx

- Use acetaminophen for fever and myalgias; aspirin should be avoided because of the associated increased risk of Reye syndrome.
- Oral acyclovir (20 mg/kg qid for 5 days), valacyclovir, or famciclovir initiated at the earliest sign (i.e., within 24 hr of illness) is useful for healthy, nonpregnant individuals 13 yr old or older to decrease the duration and severity of signs and symptoms. Immunocompromised

FIG. E1 Chickenpox. (From Swartz MH: *Textbook of physical diagnosis,* ed 7, Philadelphia, 2014, WB Saunders.)

FIG. E2 Varicella scarring. Large, deep scars are present in this patient who had secondary bacterial infection of her primary varicella lesions. (From Paller AS et al: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Varicella, complicated. Deep, ulcerative lesions occurred in this young girl with underlying immunodeficiency and secondary infection of the skin with *Streptococcus pyogenes.* (From Paller AS et al: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

hosts should be treated with intravenous acyclovir 500 mg/m^2 or 10 mg/kg q8h for 7 to 10 days.

- Varicella is most contagious from 2 days before to a few days after the onset of the rash. Varicella vaccine is available for children and adults; protection lasts at least 6 yr. Healthy, nonimmune adults and children exposed to varicella-zoster virus should receive prophylaxis with live attenuated varicella vaccine (Varivax). Patients with HIV or other immunocompromised patients should not receive the live attenuated vaccine.
- Exposed patients with contraindications to varicella vaccine can be treated with varicella-zoster immunoglobulin (VariZIG), which effectively prevents varicella in susceptible individuals. The dose is 12.5 U/kg IM up to a maximum of 625 U. VariZIG must be administered as early as possible after presumed exposure (i.e., within 10 days) for postexposure prophylaxis of varicella.
- Pruritus from chickenpox can be controlled with antihistamines (e.g., hydroxyzine 25 mg q6h) and antipruritic lotions (e.g., calamine).
- Oral antibiotics are not routinely indicated and should be used only in patients with secondary infection and infected lesions; the most common infective organisms are *Streptococcus* and *Staphylococcus* sp.

DISPOSITION

- The course is generally benign in immunocompetent adults and children.
- Infants who develop chickenpox are incapable of controlling the infection and should be given varicella-zoster immunoglobulin or gamma globulin if VariZIG is not available.

PEARLS & CONSIDERATIONS

COMMENTS

- VariZIG can be obtained from the nearest regional Red Cross Blood Center or the Centers for Disease Control and Prevention in Atlanta.
- Varicella immunization is recommended for all who have not had chickenpox; the dosage for adults and adolescents (>13 yr old) is two 0.5-ml doses 4 to 8 wk apart.

RELATED CONTENT

Chickenpox (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

A varicocele is a dilation of the testicular vein and pampiniform plexus within the scrotum.

SYNONYM

Sometimes referred to as "bag of worms" (Fig. E1)

ICD-10CM CODE
I86.1 Scrotal varices

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: A varicocele is present in up to 20% of all males. It occurs in approximately 40% of infertile men. However, only 10% to 15% of males with varicoceles have fertility problems.

RISK FACTORS: There are no reliable data on epidemiologic risk factors for varicocele, such as a family history or environmental exposures.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Although most varicoceles are painless, patients may complain of dull, aching pain that is relieved with lying down. They may also complain of testicular atrophy, one testicle being heavier than the other, a swollen testicle, or decreased fertility.
- Patients may report a mass lying posterior to and above the testis. When the patient is supine, dilation of the veins is generally decreased. Dilation and tortuosity of the veins are increased when the patient is upright and when the patient performs a Valsalva maneuver.
- The majority of cases (90%) occur more commonly on the left side because the left spermatic vein enters the left renal vein at a 90-degree angle, whereas the right testicular vein drains directly into the vena cava. Bilateral varicoceles occur in 33% of patients. A unilateral right-sided varicocele is very rare and should raise suspicion for an underlying disease causing obstruction of the vena cava.
- Physical examination reveals a soft scrotal mass that increases in size when standing and is typically described as a "bag of worms."
- Varicoceles can be graded based on physical exam. Grade 1 is small and is palpable only with Valsalva maneuver. Grade 2 is moderate and nonvisible on inspection but is palpable on standing. Grade 3 is large and visible on gross inspection.

FIG. E1 Varicocele. (From Swartz MH: *Textbook of physical diagnosis, history and examination,* ed 7, Philadelphia, 2014, Elsevier.)

ETIOLOGY

Varicoceles are caused by dysfunction of the valves in the spermatic vein, which allows pooling of blood in the pampiniform plexus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hydrocele
- Spermatocele
- Epididymal orchitis
- Testicular tumor
- Table E1 describes the differential diagnosis of pediatric scrotal masses and pain

TABLE E1 Age-Based Differential Diagnosis of Pediatric Scrotal Masses and Pain

Diagnosis	Age at Onset	Pain	Position of Testes, Tenderness	Systemic Symptoms	Comment
Testicular torsion*	All ages; peak onset at 12-18 yr	60% sudden onset; diffuse tenderness	High-riding horizontal lie	Vomiting common; dysuria and fever uncommon	
Testicular appendix torsion	Prepuberty; average age, 10 yr	Acute or gradual; focal tenderness	Normal lie; blue dot	Vomiting, dysuria, and fever uncommon	
Epididymoorchitis	>16 yr	Gradual; posterior tenderness	Normal lie	Vomiting uncommon; dysuria and fever common	Adolescent etiology: STD
Hydrocele	Most common during first yr of life	Painless	Normal lie	None	Usually resolves by age 12 mo
Inguinal hernia (incarcerated hernia, strangulated hernia*)	Most common during first yr of life	Pain with incarceration or strangulation	Normal lie	Vomiting, abdominal pain with incarceration or strangulation	Occurs 10 times more frequently in males than in females; right-sided more common
Varicocele	10-15 yr	Painless, mild discomfort, "pressure or fullness"	Normal lie	None	Associated with infertility; right-sided varicocele should prompt evaluation for tumor causing IVC compression
Testicular tumor	Rare; most occur in patients <30 yr	Painless	Normal lie, nontender mass	None unless advanced tumor	

IVC, Inferior vena cava; *STD,* sexually transmitted disease.
*Emergency condition.
From Adams JG et al: *Emergency medicine: clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.

WORKUP

Patient should undergo a testicular exam in the upright and supine position.

LABORATORY TESTS

- Laboratory evaluation is generally not indicated.
- Semen analysis may be performed if a varicocele is detected and the patient is infertile.

IMAGING

Usually varicoceles are diagnosed clinically. However, if there is suspicion for underlying malignancy, ultrasound may be used.

Rx TREATMENT

There are no clear guidelines or solid evidence for treatment. After a varicocele is identified, providers must document bilateral testicular size at regular intervals. Older men who do not want children and are asymptomatic can be treated conservatively. Surgical treatment is indicated for young men with retarded growth of a testis or abnormal sperm counts who want children.

MEDICAL MANAGEMENT

- NSAIDs are beneficial for pain relief.
- Scrotal support can reduce the feeling of "heaviness."

SURGERY

- If surgery is advisable, varicocelectomy is performed by ligation of the veins of the pampiniform plexus through an inguinal incision or by ligating the internal spermatic vein in the retroperitoneum. This is generally performed as an ambulatory surgery.
- Although surgery will reverse abnormal sperm counts, it will not necessarily reverse infertility.
- After surgery, the involved testis typically returns to its original size within 1 to 2 yr.
- The success rate of surgical repair is close to 98%; that of percutaneous repair is significantly lower.
- Sclerotherapy represents a less invasive option but is less effective in symptom reduction.

PEARLS & CONSIDERATIONS

- A varicocele in a young child may be indicative of an abdominal or retroperitoneal mass. Ultrasound should be performed.
- The sudden occurrence of a left-sided varicocele in an older man indicates occlusion of the spermatic vein and should prompt evaluation for a renal tumor.

AUTHORS: **Emily Van Kirk, MD,** and **Andrew Caraganis, MD**

SUGGESTED READING

Will MA et al: The great debate: varicocele treatment and impact on fertility, *Fertil Steril* 95(3):841-852, 2011.

BASIC INFORMATION

DEFINITION

Veins in the leg are soft, thin-walled tubes that return blood to the heart. This is accomplished by the presence of one-way valves and the action of the calf pump. Superficial venous insufficiency develops when venous return is impaired by valvular incompetence, obstruction, or calf muscle pump failure.

Varicose veins, the most common clinical manifestation of chronic venous disease, are bulging (>3 mm in diameter), tortuous conduits (Fig. E1). Reticular veins, often called "feeder veins," are bluish subdermal veins about 1 to 3 mm in diameter that give rise to telangiectasia. Spider veins or telangiectasias are very small (≤1 mm in diameter) thread veins found commonly in clusters on the surface of the skin.

SYNONYM

Chronic venous disorder

ICD-10CM CODES

I83.90	Asymptomatic varicose veins of unspecified lower extremity
I83.899	Varicose veins of unspecified lower extremities with other complications

EPIDEMIOLOGY

PREVALENCE: One large U.S. cohort study found the biannual incidence of varicose veins was 3% in women and 2% in men.

- The prevalence of varicose veins in Western populations was estimated in one study to be about 25% to 30% in women and 10% to 20% in men.

RISK FACTORS:

- Gender: Female
- Genetics: Family history of varicose veins
- Increasing age
- Multiple pregnancies

SYMPTOMS AND PHYSICAL FINDINGS

Leg complaints consistent with chronic venous disease include aching, heaviness, subjective swelling, cramps, itching, tingling, and pain. These symptoms can be exacerbated by menses, heat, and prolonged standing.

CLINICAL PRESENTATION

- Chronic vein disease is the result of the introduction of high pressures into a normal low-pressure superficial venous system.
- This increased pressure or venous hypertension causes superficial veins to distend to such a degree that vein valves fail to close, causing reflux and pooling of blood in surface veins.
- Manifested clinically by two syndromes:
  1. Junctional: Failure of the terminal valve at the intersection between the saphenous vein trunks and the deep system. If the great saphenous vein is involved, large varicose veins are found mainly above medial knee or calf. When the small saphenous vein is involved, large varicose veins are found in posterior knee or calf area. If the anterior accessory of great saphenous vein is involved, large varicose veins are found mainly in anterior or lateral thigh.
  2. Perforator: Failure of valves located in perforating vein. Large varicose veins are found most commonly in medial calf and proximal thigh region.

CLASSIFICATION

Chronic venous disease can now be classified using the Clinical-Etiology-Anatomy-Pathophysiology (CEAP) criteria to allow a precise description of the type of venous disease being discussed and provide an orderly framework for decision making (Table E1).

ETIOLOGY

- The underlying etiology of varicose veins remains uncertain.
- Important structural changes that occur: Failure of vein valve function and vein wall dilation from fragmentation of the muscle layer.

COMPLICATIONS

- Superficial venous thrombophlebitis (SVT): A very common disorder with an incidence of 125,000 new cases/yr in the U.S. The most frequent predisposing risk factors are varicose veins. The clinical findings include the presence of erythema, tenderness, and a palpable cord. Pain, increased warmth, and swelling are also present. Diagnosis is made by ultrasonography, which is useful to identify associated deep vein thrombosis that can occur in approximately 15% of patients. The location of the SVT determines the course of treatment; if the proximal great saphenous vein (GSV) is involved, a 1-mo course of low-molecular-weight heparin plus compression stockings has been found to be more effective than vein ligation. If SVT involves branch varicosities, treatment is usually symptomatic (control of pain).
- Bleeding is a more common complication than traditionally suspected. It is associated with thin-walled ectatic veins known as "blue blebs" that are found predominantly in the medial lower calf and ankle region. The best emergency treatment consists of pressure wrapping and not suture ligation, which results in delayed healing of the bleeding site. Sclerotherapy of these veins is the definitive treatment to prevent further bleeding.
- Dermal pathology of prolonged chronic venous disease (CEAP classes 4, 5, and 6).
  1. Varicose eczema
  2. Atrophie blanche
  3. Lipodermosclerosis
  4. Venous stasis ulcer
- Risks for peripheral artery disease and pulmonary embolism are slightly elevated in patients with varicose veins, but the clinical significance is unclear.[1]

FIG. E1 Varicose veins. (From White GM, Cox NH [eds]: *Diseases of the skin, a color atlas and text,* ed 2, S. Louis, 2006, Mosby.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other conditions that cause leg pain:

- Stress fracture
- Arthritis hip/knee joint
- Gout
- Degenerative disk disease of lower back

TABLE E1 CEAP Classification of Chronic Venous Disease

C: Clinical

C_0: No visible or palpable signs of venous disease
C_1: Telangiectasias or reticular veins
C_2: Varicose veins

n: No venous location identified

P: Pathophysiology

r: Reflux
o: Obstruction
r,o: Reflux and obstruction
n: No venous pathophysiology identified

CEAP, Clinical-Etiology-Anatomy-Pathophysiology.

[1]Chang SL et al: Association of varicose veins with incident venous thromboembolism and peripheral artery disease, *JAMA* 319:807-817, 2018.

- Intermittent claudication secondary to peripheral arterial disease (PAD)
- Medications such as allopurinol and statins

Other conditions that cause leg swelling:

- Cellulitis
- Soft tissue injury to leg/ankle/foot
- Obesity
- Diabetes
- Advancing age
- Medications such as calcium channel blockers, steroids, monoamine oxidase inhibitors, and tricyclics

WORKUP

The diagnosis of chronic venous disorders is predominantly clinical. Initial evaluation consists of a thorough history and physical exam with classification of disease according to the CEAP criteria.

LABORATORY TESTS

Laboratory tests are not useful in patients with varicose veins.

IMAGING STUDIES

Duplex ultrasonography:

- Gold-standard imaging modality for the diagnosis, prognostic evaluation, pretreatment mapping, and posttreatment assessment of therapeutic intervention.
- Duplex ultrasound is used to identify and quantify points of valvular reflux within the superficial venous system.
- Assessment of valvular reflux is done with patient in the upright position, which physiologically approximates the condition in which valvular reflux occurs.
- Reverse flow of greater than 0.5 sec after distal compression is considered abnormal.

Other tests:

- Air plethysmography: May be useful in patients who have reflux in both superficial and deep venous systems or in patients with an unusual presentation of leg pain.
- Venography: Has been largely replaced by duplex ultrasonography but still retains a critical role in the evaluation of chronic venous insufficiency prior to venous reconstruction.

Rx TREATMENT

CONSERVATIVE THERAPY:

- Aerobic exercise regularly for 30 min a day.
- Elevate legs above heart level to reduce swelling.
- Flex ankles frequently at work and during air travel or long car travel.
- Maintain proper weight.
- Graduated compression stockings (below knee) to alleviate symptoms in patients who are not candidates or do not desire to undergo treatment of their varicose veins.

SCLEROTHERAPY:

- Small- to medium-sized varicose veins such as spider veins and reticular varices in the absence of reflux in saphenous trunks are best treated with liquid sclerotherapy.
- The three principal sclerosants used in the U.S. are hypertonic saline, sodium tetradecyl sulfate, and the newly FDA-approved solution, polidocanol.
- These agents are injected into vessels using 27-gauge or 30-gauge needles at concentrations of 23.4%, 0.1%, or 0.5%, respectively, causing injury to the endothelium with the resultant disappearance of the vein over period of time (usually 8 to 12 wk).

AMBULATORY PHLEBECTOMY:

- A procedure in which large varicose vein branches are removed with special hook instruments through a small puncture—incisions are made with an 18-gauge needle or No. 11 blade
- Performed safely under local anesthesia in an office setting and offers excellent cosmetic results and relief of symptoms
- Most commonly performed in conjunction with endovenous ablation procedures

ENDOVENOUS ABLATION:

- Ablation of diseased saphenous vein trunks, large incompetent tributaries, or perforating veins can be achieved by using:
  1. Radiofrequency energy
  2. Laser energy
  3. Ultrasound-guided foam sclerotherapy
- The first two accomplish thermal injury to the vein in situ via an intraluminal catheter or bare-tipped laser wire. Chemical ablation uses a solution (polidocanol or sodium tetradecyl sulfate) that is injected directly into the vein in the form of foam.
- Endovenous ablation can be performed in an office setting using local anesthesia. Patients can return to their normal daily activities immediately.
- The efficacy of these endovenous ablation procedures has been borne out by numerous published reports with occlusion rates over 95% and reflux free rates over 5-yr follow-up of 86%. A recent trial comparing ultrasound-guided foam sclerotherapy and endovenous laser ablation revealed that quality of life measures were generally similar among the study groups, with the exception of a slightly worse disease-specific quality of life in the foam group than in the surgery group. Both treatments had similar efficacy, but complications were less frequent after laser treatment and ablation rates were lower after foam treatment.

DISPOSITION

- In a recent randomized trial[2] of treatments for varicose veins, disease-specific quality of life 5 yr after treatment was better after laser ablation or surgery than after foam sclerotherapy.
- It is important that the physician educate the patient to understand that varicose veins are a chronic and progressive disease.
- Any treatment is at best palliative, as patients in time will develop varicose veins in other areas.

REFERRAL

To either a phlebologist, preferably board certified by the newly created American Board of Phlebology, or a residency-trained vascular surgeon

BASIC INFORMATION

DEFINITION

Vasculitis refers generically to inflammation occurring within the walls of blood vessels. Blood vessel inflammation can result in either perforation of affected vessels with hemorrhage into adjacent structures or thrombosis with subsequent ischemia and infarction of supplied tissues. Vasculitis can occur as a primary process or secondary to another connective tissue disease, infection, or drug exposure. The systemic vasculitides are a heterogeneous group of disorders (Table 1) characterized by blood vessel inflammation affecting vessels of varying size and location resulting in a wide range of clinical manifestations dictated largely by which vessels are affected (Fig. 1 and Fig. E2). Vasculitis is traditionally classified according to the size of the blood vessels predominantly affected (Table 2). Antineutrophilic cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV) includes granulomatosis with polyangiitis (GPA); microscopic polyangiitis (MPA), including renal-limited vasculitis (RLV); and eosinophilic granulomatosis with polyangiitis (EGPA). All are associated with ANCA and have similar features on renal histology (e.g., a focal necrotizing, and often crescentic, pauciimmune glomerulonephritis). Several of these are covered in individual topics, including topics on granulomatosis with polyangiitis (GPA), polyarteritis nodosa (PAN), giant cell arteritis (GCA), Takayasu arteritis, and Henoch-Schönlein purpura (HSP). Severity varies between and within specific vasculitides from a relatively benign, self-limited process to severe, life-threatening multisystem organ involvement with significant morbidity and mortality.

ICD-10CM CODES

M30.0	Polyarteritis nodosa
M30.3	Mucocutaneous lymph node syndrome [Kawasaki]
M31.30 31	Wegener granulomatosis without renal involvement
M31.5	Giant cell arteritis with polymyalgia rheumatica
M31.6	Other giant cell arteritis
M31.4	Aortic arch syndrome [Takayasu]
D 69.0	Allergic purpura
L95.9	Vasculitis limited to the skin, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- The epidemiology and demographics of the various vasculitides vary by the individual disease and, where applicable, are covered under the relevant vasculitis disease chapters.
- The most common form of systemic vasculitis in the U.S. is giant cell arteritis, with an approximate incidence of 170 cases per 1 million per yr in individuals older than 50 yr.
- Antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis is significantly less common with aggregate incidence estimated at approximately 20 per million in the U.S.
- Age distribution can demonstrate significant variability between the vasculitides as shown by the fact that GCA generally does not occur before age 50, while 90% of cases of HSP occur in the pediatric population, and 80% of patients with Kawasaki disease are under age 5.
- Although genetic factors clearly play a role in disease susceptibility, familial cases of vasculitis are rare.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical presentation often includes nonspecific constitutional symptoms including fever, malaise, headache, and weight loss.

TABLE 1 Comparing the Vasculitides

Disease	Pathophysiology	Classic Features	Testing	Treatment
Giant cell arteritis	Mononuclear cell infiltration and giant cell formation	Headache, scalp tenderness, visual disturbance	ESR CRP biopsy	Prednisone and aspirin
Takayasu arteritis	Mononuclear cell infiltration and giant cell formation	Visual disturbance, chest pain, abdominal pain, differences in extremity blood pressure and pulses	Angiography	Prednisone Surgical or angiographic intervention
Polyarteritis nodosa	Polymorphonuclear infiltration	Fever, hypertension, myalgias, abdominal pain, hematuria, CHF, GI bleeding, orchitis	ESR, CRP biopsy Angiography	Prednisone (mild disease) plus cyclophosphamide (moderate-severe disease) Antiviral therapy if concurrent hepatitis B or C Azathioprine or methotrexate for maintenance of remission
Kawasaki disease	Polymorphonuclear infiltration	5-day fever, conjunctivitis, oral lesions, rash, red palms and soles, edema, cervical lymphadenopathy	ESR, CRP Leukocytosis Thrombocytosis Echocardiography	Aspirin plus IV gamma globulin
Granulomatosis with polyangiitis (Wegener granulomatosis)	Granuloma formation secondary to aggregating neutrophils	Upper and lower respiratory symptoms, renal insufficiency, skin lesions, visual disturbance	ESR CRP c-ANCA	Prednisone and methotrexate (mild disease) Cyclophosphamide or rituximab plus prednisone (moderate to severe disease)
Eosinophilic granulomatosis with polyangiitis (Churg-Strauss syndrome)	Eosinophilic infiltration Allergic granulomas	Allergic rhinitis, nasal polyps, asthma	Leukocytosis Eosinophilia ESR, CRP biopsy	Prednisone with or without cyclophosphamide
Henoch-Schönlein purpura	IgA complex deposition	Palpable purpura, arthralgias, GI disturbances, glomerulonephritis	Leukocytosis Eosinophilia Ig A elevation, skin biopsy	Usually self-limited NSAIDs Prednisone if necessary Rituximab (refractory cases)
Cryoglobulinemic vasculitis	Cold precipitable monoclonal or polyclonal immunoglobulins	Palpable purpura, glomerulonephritis, myalgias, weakness, peripheral neuropathy	Low complement levels, hepatitis C Renal biopsy	Rituximab with or without prednisone Peg interferon plus ribavirin (HCV infection)
Cutaneous leukocytoclastic vasculitis	Neutrophilic infiltration Mononuclear and eosinophilic infiltration	Palpable purpura, macules, vesicles, bullae, urticaria	Skin biopsy	Prednisone Colchicine Dapsone
Behçet syndrome	Polymorphonuclear infiltration	Recurrent oral aphthous ulcers, genital ulcers, skin lesions, visual disturbance	ESR, CRP leukocytosis Oral mucosa autoantibodies	Topical corticosteroids Prednisone with azathioprine (end-organ disease) Colchicine (aphthous ulcer and arthritis) Infliximab (refractory disease)

c-ANCA, Cytoplasmic antineutrophil cytoplasmic antibody; *CHF,* congestive heart failure; *CRP,* C-reactive protein; *ESR,* erythrocyte sedimentation rate; *GI,* gastrointestinal; *IgA,* immunoglobulin A; *IV,* intravenous.
From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.

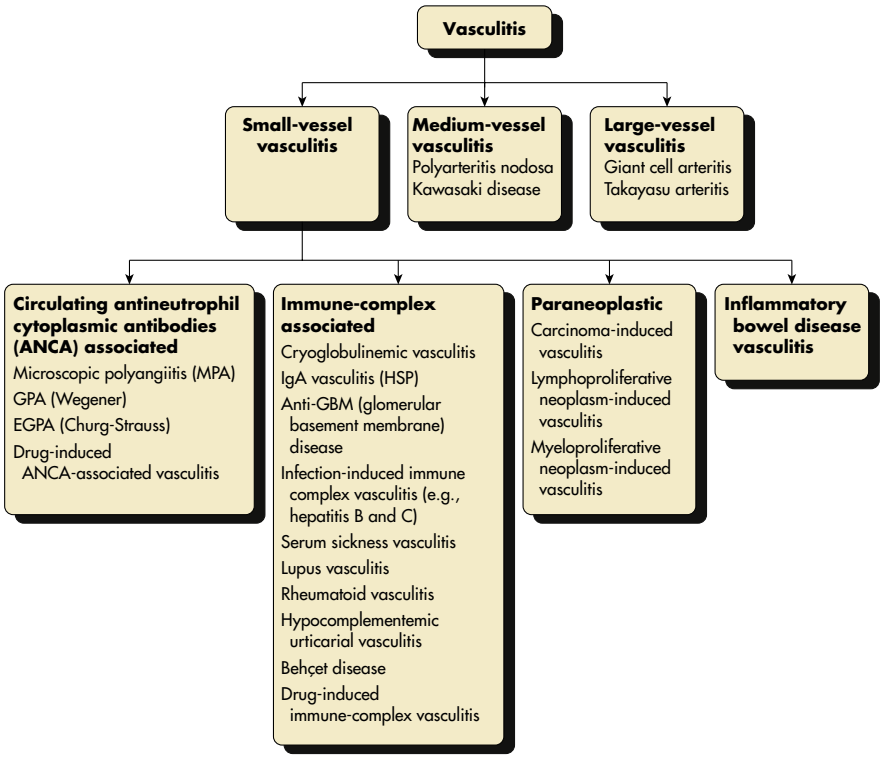

FIG. 1 Major categories of noninfectious vasculitis. Not included are vasculitides that are known to be caused by direct invasion of vessel walls by infectious pathogens, such as rickettsial vasculitis and neisserial vasculitis. *EGPA,* Eosinophilic granulomatous polyangiitis; *GPA,* granulomatous polyangiitis; *HSP,* Henoch-Schönlein purpura. (From Freehally J et al: *Comprehensive clinical nephrology,* ed 6, Philadelphia, 2019, Saunders.)

- Signs and symptoms are generally dictated by the tropism of involved vessels.
- Skin manifestations of vasculitis include petechiae, palpable purpura (Fig. E3), subcutaneous nodules, livedo reticularis, ulcerations, and digital ischemia.
- Kidney involvement of medium-sized and large vessel vasculitis is often in the form of renovascular hypertension. Glomerulonephritis may be seen in small vessel vasculitis.
- Pulmonary small vessel involvement can cause alveolar hemorrhage, which can present with cough, dyspnea, and alveolar hemorrhage.
- Mononeuritis multiplex is the characteristic finding of vasculitis affecting the vasa nervorum of the peripheral nervous system.
- Gastrointestinal involvement of the mesenteric vasculature can cause postprandial pain, bleeding, and perforation.
- Arthritis, while nonspecific, can be present.
- Significant clinical variability exists between the various vasculitides, although overlapping symptoms may be seen.

ETIOLOGY

Most forms of systemic vasculitis are of unknown etiology. Cryoglobulinemia vasculitis is often secondary to hepatitis C infection, and cutaneous leukocytoclastic vasculitis is often related to a drug exposure.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infective endocarditis
- Atrial myxoma
- Cholesterol emboli
- Malignancy
- Hypercoagulopathy
- Congenital collagen vascular disorder

WORKUP

- The diagnosis of most forms of systemic vasculitis relies on the history and physical examination as well as supportive laboratory testing. Table 3 describes differential diagnostic features of selected forms of small vessel vasculitis.
- Tissue biopsy is important in establishing an accurate diagnosis; biopsy sites should target affected tissues.
- Imaging such as mesenteric angiography can be supportive and may obviate the need for tissue biopsy.

LABORATORY TESTS

- Laboratory markers of systemic inflammation include elevated erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and anemia of chronic disease.
- ANCA targeting myeloperoxidase (MPO) and proteinase 3 (PR3) are frequently found in several small vessel vasculitides, including GPA (Wegener), microscopic polyangiitis (MPA), and EGPA (Churg-Strauss).
- Hepatitis C antibodies and rheumatoid factor are often present in cryoglobulinemic vasculitis.
- Urinalysis in patients with glomerulonephritis due to small vessel ANCA-associated vasculitis will generally demonstrate hematuria with active urinary sediment, with red blood cell casts and proteinuria.

IMAGING STUDIES

- CTA, MRA, and angiography can demonstrate vascular narrowing and aneurysm formation in suspected medium-size and large-vessel vasculitis.
- Pulmonary and sinus CT scans can demonstrate active pulmonary and upper airway disease in ANCA-associated vasculitis.

TABLE 2 Classification Scheme of Vasculitides According to Size of Predominant Blood Vessels Involved

- Primary vasculitides
- Predominantly large vessel vasculitides
- Takayasu arteritis
- Giant cell arteritis (temporal arteritis)
- Cogan syndrome
- Behçet disease*
- Predominantly medium-sized vessel vasculitides
- Polyarteritis nodosa
- Cutaneous polyarteritis nodosa
- Buerger disease
- Kawasaki disease
- Primary angiitis of the central nervous system
- Predominantly small vessel vasculitides
- Immune complex mediated
- Goodpasture disease (anti-glomerular basement membrane disease)†
  1. Cutaneous leukocytoclastic angiitis ("hypersensitivity vasculitis")
  2. Henoch-Schönlein purpura
  3. Hypocomplementemic urticarial vasculitis
  4. Essential cryoglobulinemia‡
  5. Erythema elevatum diutinum
- ANCA-associated disorders§

Rx TREATMENT

Treatment of vasculitis depends on the specific type of vasculitis and is tailored to the severity of disease activity. Novel treatments are covered under the relevant vasculitis disease chapters.

ACUTE GENERAL Rx

- Systemic corticosteroids are generally required to gain initial control of active vasculitis, although mild cases of drug-induced cutaneous leukocytoclastic vasculitis often require cessation of the offending medication and at times, low-dose corticosteroid use.
- HSP and vasculitis limited to the skin, including cutaneous PAN, can often be managed without further immunosuppression.
- Major organ-threatening disease in systemic vasculitis has traditionally required pulse steroids and oral or intravenous cyclophosphamide for induction of remission.
- Studies have demonstrated noninferiority of rituximab compared to cyclophosphamide in ANCA-associated vasculitis with major organ involvement, and it is approved for this use.
- Rituximab with prednisone has also recently been shown to be effective in the treatment of relapsing flares of disease activity in ANCA-associated vasculitis.
- Similarly, rituximab has been used for maintenance of remission.
- Less severe disease such as granulomatosis with polyangiitis limited to the upper airways can be managed with methotrexate rather than cyclophosphamide.
- Trimethoprim/sulfamethoxazole should be used to prevent *Pneumocystis carinii* infection with concurrent immunosuppressive therapy.
- The goal of acute therapy is to induce remission of disease activity and is generally continued for 1 to 2 mo once this is achieved, at which point chronic therapy is used.

CHRONIC Rx

- The goal of chronic therapy is to prevent disease relapse and minimize medication side effects.
- Steroids are gradually tapered as allowed by disease activity.
- Immunomodulatory agents such as methotrexate or azathioprine are commonly used for maintenance therapy in place of cyclophosphamide to reduce side effects.
- Cryoglobulinemic vasculitis due to chronic hepatitis C will often improve with treatment of the underlying viral infection.
- Rituximab may also be an appropriate remission maintenance agent in ANCA-associated vasculitis, although frequency of dosing and duration of therapy are not yet well characterized.

DISPOSITION

Varies widely among the various vasculitides

REFERRAL

Systemic vasculitis care is generally coordinated by a rheumatologist. Renal, pulmonary, neurologic, and gastrointestinal consultation is often needed when vasculitis involves these organ systems. Isolated cutaneous leukocytoclastic vasculitis is often managed by dermatology.

BASIC INFORMATION

DEFINITION

The spectrum of chronic venous disease (CVD) ranges from varicose veins to leg edema and skin manifestations consisting of hyperpigmentation, eczema, lipodermatosclerosis, and venous ulcer. These latter venous-specific skin changes constitute an advanced form of CVD known as chronic venous insufficiency (CVI).

SYNONYMS

Stasis dermatitis
Postthrombotic syndrome (PTS)
Chronic venous disease

ICD-10CM CODES

I87.2	Venous insufficiency (chronic) (peripheral)
I87.8	Other specified disorders of veins
I87.9	Disorder of vein, unspecified
I83.10	Varicose veins of unspecified lower extremity with inflammation

EPIDEMIOLOGY & DEMOGRAPHICS

- From 10% to 35% of adults in the United States have some form of CVI.
- Venous ulcers are the complication of CVI that results in the greatest morbidity and affects 4% of people over the age of 65.
- The population-based costs to the U.S. government for CVI treatment and venous ulcer care have been estimated at >$1 billion/yr.
- In addition, 4.6 million workdays/yr are lost to chronic venous-related diseases.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The manifestations of CVI can be viewed using the internationally accepted classification system, CEAP (clinical, etiology, anatomy, and pathophysiology) (Table 1). The spectrum of cutaneous changes of CVI in the affected leg include:

- Varicose eczema: The most common and earliest sign, this involves the skin above the medial ankle and consists of pruritic, red, and scaly eczematous patches and plaques.
- Hyperpigmentation: Caused by the breakdown of red blood cells and leads to hemosiderin deposition and dark staining of the skin (Fig. E1).
- Atrophie blanche: Usually presents as hypopigmented white patches with focal red punctate dots or telangiectasia surrounded by hyperpigmentation. Skin in this condition is avascular and prone to ulceration (Fig. E2).
- Lipodermatosclerosis: A chronic, brawny induration of the skin and underlying fat that usually involves the skin from medial malleolus up to the lower border of the calf. Progression of the disease leads to an "inverted champagne bottle" appearance. The induration and lack of perfusion of the skin in this area make it susceptible to ulcer formation.

TABLE 1 CEAP Classification

Clinical Classification	
C_0	No visible or palpable signs of venous disease
C_1	Telangiectasias or reticular veins
C_2	Varicose veins; diameter >3 mm
C_3	Edema
C_4	Changes in skin and subcutaneous tissue: Pigmentation, eczema, lipodermatosclerosis, or atrophie blanche
C_5	Healed venous ulcer
C_6	Active venous ulcer
	Each limb is further classified as asymptomatic (A) or symptomatic (S)
Etiologic Classification	
E_C	Congenital
E_P	Primary
E_S	Secondary (post-thrombotic)
E_N	No venous cause identified
Anatomic Classification	
A_S	Superficial veins
A_P	Perforator veins
A_O	Deep veins
A_N	No venous location identified
Pathophysiologic Classification	
P_R	Reflux
P_R	Obstruction
$P_{R,O}$	Reflux and obstruction
P_N	No venous pathophysiology identifiable

CEAP, Clinical-Etiological-Anatomical-Pathophysiological.
From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, 2017, Elsevier.

ETIOLOGY

- CVI occurs as a result of sustained venous hypertension in the leg, which can be caused by the following:
  1. Primary: Vein valve failure with reflux in the superficial venous system or perforating veins (most common cause of CVI).
  2. Secondary: Post-thrombotic syndrome in which a deep vein thrombosis causes outflow obstruction *or*
  3. Combination of the two previous processes.
- This sustained elevation in venous pressure or venous hypertension results in pathologic effects in the skin and subcutaneous tissues such as edema, eczema, hyperpigmentation, fibrosis, and ultimately venous ulceration.

DIAGNOSIS

The diagnosis and evaluation of CVI are directed primarily by a detailed history and physical examination.

DIFFERENTIAL DIAGNOSIS

- Contact dermatitis
- Atopic dermatitis
- Cellulitis
- Dermatophyte infection
- Pretibial myxedema
- Nummular eczema
- Xerosis
- Asteatotic eczema

WORKUP

The primary goal is to identify the cause of sustained venous hypertension. Fig. 3 describes the evaluation and management of chronic venous insufficiency.

LABORATORY TESTS

Generally not indicated

IMAGING STUDIES

- Evaluation of the patient is performed in the standing position with duplex ultrasonography to identify reflux in the superficial, deep, and perforating veins as well as obstruction of the deep veins.
- No exam of a leg with CVI is complete without palpation of pulses and/or determination of ankle-brachial index (ABI).

TREATMENT

NONPHARMACOLOGIC THERAPY

- Leg elevation above heart level for 30 min three to four times a day
- Weight reduction because obesity is a risk factor for deep vein thrombosis and CVI
- Walking exercises to improve calf function
- Physical therapy to improve ankle joint mobility
- For weeping skin lesions, wet-to-dry dressing changes

ACUTE GENERAL Rx

- The fundamental role of compression in the treatment of CVI is well recognized and has been validated by randomized controlled trials (RCTs).
- The beneficial effects of gradient compression stockings (decrease in edema and control of discomfort) are due to their effect on microvascular hemodynamics and Starling forces.
- Below-knee compression stocking with a gradient of at least 20 to 30 mm Hg will control edema, alleviate pain, and improve the quality of life in CVI patients.
- Compression stockings are contraindicated in patients with an ABI of <0.6.
- Some patients (acute lipodermatosclerosis) may benefit from nonelastic compression with the Unna gel paste gauze boot to alleviate their symptoms and acute increase in their swelling. The Unna boot is changed once a week.
- Topical corticosteroid creams or ointments (e.g., triamcinolone 0.12% bid) may be used to help reduce inflammation and itching. Steroids should never be applied to ulcer.
- Antibiotics should only be used when treating a clinically apparent, culture-proved infection. Most secondary infections are the result of *Staphylococcus* or *Streptococcus* organisms.
- Diuretics have no role in the treatment of CVI-related edema.

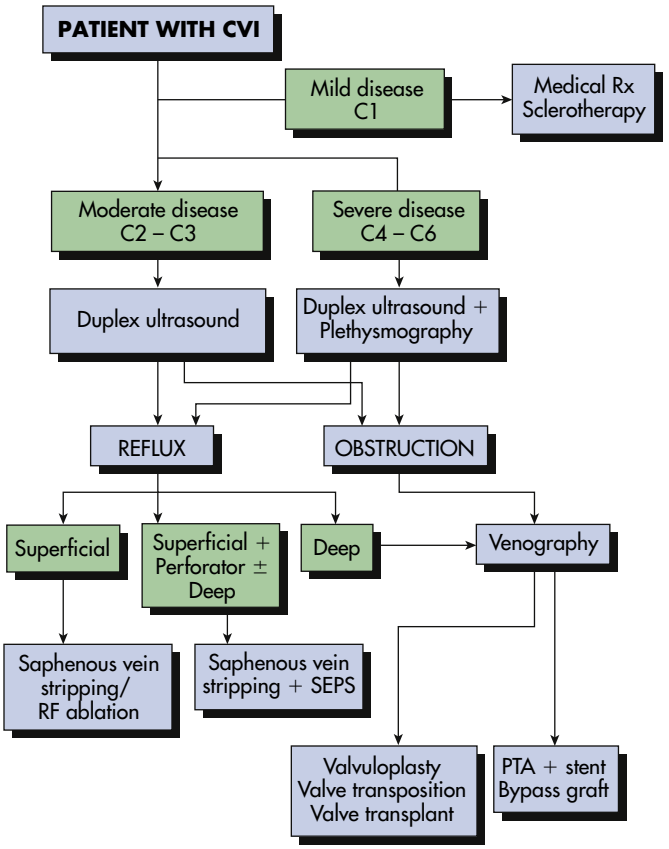

FIG. 3 Evaluation and management of chronic venous insufficiency. (From Cameron JA: *Current surgical therapy "varicose veins,"* Philadelphia, 2004, Saunders.)

CHRONIC Rx

- While conservative care is fundamental, patients with CVI should be considered for correction of their underlying venous hypertension.
- The majority of patients with CVI have superficial vein or perforator vein reflux as their underlying pathology and would benefit from the newer vein ablation procedures listed below.
  1. Endovenous ablation of superficial (saphenous) or perforator vein reflux.
  2. RF ablation with VNUS closure.
  3. Endovenous laser therapy (EVLT).
  4. Ultrasound-guided foam sclerotherapy.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Several groups of drugs have been evaluated in the treatment of CVI, including coumarins, flavonoids, and saponosides (horse chestnut extracts). These drugs have venoactive properties and are widely used in Europe but are not approved for use in the U.S. The precise mechanism of action is not known. Horse chestnut seed extract has been found, in the short term, to be as effective as compression stockings in reducing pain and edema, but long-term efficacy has not been established.

REFERRAL

- Phlebology
- Vascular surgery
- Indications for referral:
  1. Skin and subcutaneous changes consistent with CVI
  2. Associated peripheral arterial insufficiency (PAD)
  3. Longstanding varicose vein disease
  4. Consideration for vein ablation procedure

PEARLS & CONSIDERATIONS

COMMENTS

- Inflammatory skin changes from CVI are irreversible. The goal of therapy is to eliminate venous hypertension and prevent progression.
- Venous ulcers are often an end-stage manifestation of CVI. Refer to "Venous Ulcers" for more information.

FIG. E1 Stasis dermatitis, venous insufficiency. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

FIG. E2 Chronic venous ulcer likely to be resistant to treatment as it involves the space behind the medial malleolus, which is difficult to compress. (From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, 2017, Elsevier.)

BASIC INFORMATION

DEFINITION

Venous ulcers are defined as chronic defects of the skin that fail to heal spontaneously and persist for longer than 4 wk. Venous ulcers account for about 70% of all lower-extremity ulcerations. They are usually located in the "gaiter" region and can be accompanied by varicose veins, edema, hyperpigmentation, and lipodermatosclerosis. Venous ulceration develops in patients as a result of sustained venous hypertension.

SYNONYM

Stasis ulcers

ICD-10CM CODES	
I87.2	Venous insufficiency (chronic) (peripheral)
L97.909	Non-pressure chronic ulcer of unspecified part of unspecified lower leg with unspecified severity

EPIDEMIOLOGY & DEMOGRAPHICS

In industrialized nations, up to 1.5% of the population will suffer from venous ulcers. In patients ≥65 yr, the incidence increases to 4%. In the U.S., >500,000 people suffer from stasis ulcers.

RISK FACTORS

- Obesity
- Increasing age
- Family history of chronic venous insufficiency
- History of deep venous thromboembolism

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Venous ulcers are most commonly located in the lower leg just above the ankle (gaiter region). They are a partial-thickness, irregularly shaped wound with well-defined borders with granulation tissue and fibrin present in the ulcer base (Fig. E1). Venous ulcers are relatively painless and are surrounded by brown-stained skin and/or dry, itchy, and reddened skin. In about 50% of patients, there are visible varicose veins in an aching, swollen leg.

ETIOLOGY

The exact mechanism of the role of venous hypertension in the etiology of venous ulcers is not certain. Hemodynamic forces such as venous hypertension, circulatory stasis, and modified conditions of shear stress appear to play an important role in an inflammatory reaction accompanied by leukocyte activation that clinically leads to fibrosclerotic remodeling of the skin and then to ulceration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Arterial ulcer
- Neurotrophic ulcers (located predominantly in the foot)
- Vasculitis
- Pyoderma gangrenosum
- Ulcerated skin tumors like basal cell or squamous cell carcinoma (Marjolin ulcer)
- Rheumatoid arthritis

WORKUP

- The history and clinical signs and symptoms of leg ulcers are often misleading and may not differentiate venous ulcers from other leg ulcers; about 30% of leg ulcers are not of venous origin.
- Measurement of the ankle-brachial index (ABI) is essential in excluding peripheral arterial disease (PAD), which can be present in 20% of patients and is required before starting compression therapy. Arterial insufficiency is suggested by an ABI <0.9.
- Patients with lower-extremity ulcers should also be evaluated for diabetes.
- Coagulation defects have been found in 40% of patients with leg ulcers. This finding suggests that many patients with leg ulcers have a known or suspected history of deep venous thrombosis and a thrombophilia workup is indicated.
- If vasculitis is suspected, a biopsy of the edge of the ulcer can confirm the diagnosis.
- Any wound that has failed to improve after therapy of 4 wk should have a biopsy to rule out malignancy.

IMAGING STUDIES

- Evaluation of patients with venous leg ulcer should include duplex sonography to identify reflux in the superficial, deep, and perforating veins as well as possible obstruction of the deep veins.
- If the ulcer appears to be infected, consider tissue for culture, plain x-ray films, and bone scan to evaluate for osteomyelitis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Fig. 2 describes an algorithm for the treatment of venous ulcers.
- Surgical debridement to remove all nonviable material can be accomplished in the office setting with the use of a topical xylocaine gel. Debridement produces the release of growth factors that allow the development of healthy granulation tissue and the initiation of the healing process.
- The first-line treatment of ulcers includes below-knee compression stockings to improve venous return to the heart, thereby decreasing edema, inflammation, and tissue ischemia (used only if the ABI is between 0.6 and 0.85 because compression can cause limb ischemia).
- There is Level A evidence that graduated compression stockings alone can lead to healing of a venous ulcer. The stockings should be worn during the day and removed at night.
- Regular, brisk walking 30 min a day, five times a week is recommended.
- Elevate leg above heart level and raise the foot of bed with 3-in blocks to reduce edema.
- Role of surgery: In a randomized controlled trial, endovenous catheter ablation of superficial reflux showed no improvement in the healing rate of ulcers but did demonstrate a reduction of ulcer recurrence from 28% to 12% at 12 mo.

ACUTE GENERAL Rx

- Dressings are used under compression stockings to provide a clean, moist environment to promote healing.
- Modern, more complex dressings have been developed and include occlusive and semiocclusive dressings, classified according to their physical composition and ability to control wound drainage.
- Semiocclusive dressings have varying ability to absorb wound drainage. Some examples of this type are hydrocolloids (DuoDerm), hydrogels (DuoDerm hydrogel), foam dressings (Allevyn), and alginates.
- Biologic wound dressings (Apligraf) and tissue-engineered products (Oasis) have been developed, and these products can either directly provide growth factors or indirectly stimulate growth factors in the ulcer bed.
- Pentoxifylline (800 mg tid) has been shown to be an effective adjuvant to compression therapy as reported in a meta-analysis of nine clinical trials.
- Skin grafting should be considered for large or refractory ulcers as long as the wound is clean and there is healthy granulation tissue.
- Published randomized clinical trials on the value of the different types of dressings in the management of leg ulcers have not shown effects on ulcer healing. Despite the lack of evidence to support their use, modern dressings remain a part of the standard of care. Decisions regarding their use should be based on local cost of the dressings and the physician's clinical experience.
- Trials involving the use of weekly, low-dose, high-frequency ultrasound for hard-to-heal venous leg ulcers do not support adding therapeutic ultrasound to standard care for venous leg ulcers.

DISPOSITION

The overall prognosis for this condition is poor; the healing rate depends on the initial size of the ulcer. Although 65% to 70% of venous ulcers are healed within 6 mo, the 5-yr recurrence rate of healed venous ulcers can be as high as 40%. Maintenance of lifelong compression therapy is recommended.

REFERRAL

All patients should be evaluated weekly during the first month of therapy. Nonhealing ulcers with little to no improvement should also be referred to a wound care clinic.

Ventricular Fibrillation

BASIC INFORMATION

DEFINITION

Ventricular fibrillation (VF) is a rapid, disorganized ventricular arrhythmia (Fig. E1) that renders the ventricle unable to contract in a synchronized manner resulting in no meaningful cardiac output or blood pressure and, if not rapidly interrupted, death. The ECG appearance of VF can evolve rapidly over the course of minutes as the heart becomes more ischemic. Upon initiation, QRST complexes in VF often appear coarse with grossly irregular oscillating complexes of variable rate, axis, and morphology. As VF continues, the QRST complexes become finer, lower amplitude, and slower, eventually resulting in asystole. VF is the leading mechanism of sudden cardiac death.

ICD-10CM CODE
I49.01 Ventricular fibrillation

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: A peak incidence of VF occurs in the first 48 hrs after an acute myocardial infarction (MI). The true incidence of VF is impossible to know because the majority of these episodes are in unmonitored patients and result in sudden cardiac death. Sudden cardiac death, as determined by death certificate analysis, is estimated to account for 400,000 to 450,000 deaths per yr in the U.S. In small studies in which patients were wearing monitoring at the time of death, the majority of sudden cardiac deaths were caused by VF (60% to 70%). The true proportion of sudden cardiac deaths caused by VF is highly dependent on the population studied.

RISK FACTORS:

- Between 80% and 90% of sudden cardiac death and VF cases occur in patients with coronary artery disease (CAD) or systolic dysfunction, with only about 15% of VF cases occurring in a "normal" heart at autopsy.
- Between 60% and 70% of patients with VF have CAD.
- Between 5% and 15% of events are secondary to structural heart disease (congenital coronary anatomy, myocarditis, hypertrophic cardiomyopathy, arrhythmogenic right ventricular cardiomyopathy). This frequency increases when under the age of 35 yr.
- Between 5% and 10% of events occur in the absence of ischemic or structural heart disease. These events are more common before the age of 35 and include inherited channelopathies and trauma-induced (commotio cordis) etiologies.
- Risk factors for VF in patients presenting with ischemic coronary heart disease:
  1. STEMI as opposed to NSTEMI
  2. Larger infarcts
  3. Inferior infarcts
  4. Baseline repolarization abnormalities
  5. Hypokalemia
  6. Male sex
  7. History of tobacco abuse
  8. Absence of pre-infarct angina

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients are unconscious, without blood pressure or pulse.
- Witnesses may describe a sudden loss of consciousness, without breathing along with a cyanotic appearance.
- Seizure activity may be witnessed after loss of consciousness caused by a lack of cerebral perfusion.

ETIOLOGY

In roughly 80% of patients with VT/VF there is increased ventricular ectopy prior to sustained ventricular arrhythmia. VF is thought to develop in one of three ways: (1) degeneration of sustained monomorphic VT, (2) degeneration of sustained polymorphic VT, or (3) development of VF as a primary event. The mechanism of VF is thought to involve multiple rotating spiral waves of micro reentry without any overall organized electrical activity. This is distinctly different from the predominant mechanism of monomorphic ventricular tachycardia, which is reentry around a fixed zone of slow conduction, typically ventricular scar. VF results from a substrate of heterogeneous repolarization and a triggering event such as critically timed PVC. In about one third of these cases the PVC initiates VT by an early R-on-T PVC, and the remaining two thirds occur after a late-cycle PVC. Repolarization of the heart is an active process requiring ATP to obtain and maintain a negative resting membrane potential via NA/K ATPase ion channels. By depriving a significant amount of myocardium to oxygen and thus the ability to generate ATP, ischemia can provide both the substrate of VF by impairing the ischemic area's ability to fully repolarize and allow for a triggering event by allowing spontaneous depolarization. Genetic conditions such as Long QT syndrome can also predispose to VF in absence of ischemia by providing more heterogeneous repolarization within the myocardium.

ETIOLOGIES OF VF IN ABSENCE OF STRUCTURAL OR CORONARY HEART DISEASE

- **Long QT syndrome:** Estimated prevalence of 1:2000 to 1:5000; the diagnosis is made based on combination of ECG findings and clinical and family history collectively compiled as Schwartz criteria. Typically inherited as autosomal dominant mutation with variable penetrance, making genetic testing helpful for confirming diagnosis or screening family members.
- **Short QT syndrome:** Inherited syndrome characterized by both a short QTc (<350 ms in males and 360 ms in females) and symptomatic atrial fibrillation and VF.
- **Brugada syndrome:** Prevalence is 5 to 50:10,000 of autosomal dominant inherited mutation characterized by a classic Brugada pattern on ECG in leads V1 to 2 combined with syncope or clinical sudden death. The ECG pattern is mutable and not always present. Genetic testing is limited.
- **Wolff-Parkinson-White syndrome:** 2% to 3% of sudden cardiac arrest due to WPW caused by AF conducting down bypass tract degenerating into VF.
- **Idiopathic VF:** Diagnosis of exclusion typified by VF induced by early coupled PVCs typically emanating from conduction system. Notably suppressed by isoproterenol and quinidine.
- **Early repolarization syndrome:** Typified by 1-mm ST elevation in two sequential inferior or lateral leads. This ECG pattern is quite nonspecific, occurring in 5% to 10% of general population and increasing risk of sudden death by threefold, or roughly 0.3%.
- **Commotio cordis:** VF as a result of low-velocity projectile impact on the chest wall inducing VF in the absence of sudden death. This is uncommon and occurs in young, typically male, individuals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis of an ECG suspicious of VF includes:

- ECG artifact
- Atrial fibrillation with aberration
- Polymorphic ventricular tachycardia

WORKUP

- Ischemia evaluation is paramount. Cardiac biomarkers should be checked and cardiac catheterization should be performed in most cases.
- A 12-lead ECG of the tachycardia should always be obtained and, whenever possible, compared to the ECG in sinus rhythm if there is any uncertainty about the diagnosis.
- Basic lab testing with focus on electrolytes levels (K and Mg) and hemoglobin.

LABORATORY TESTS

- Electrolyte levels potassium, magnesium
- Hemoglobin level
- Cardiac biomarkers
- Genetic testing should be reserved for specific situations such as when there is a concern for genetically mediated conditions such as hypertrophic cardiomyopathy, catecholaminergic polymorphic ventricular tachycardia or Brugada syndrome

IMAGING STUDIES

- Echocardiogram (rule out structural heart disease).

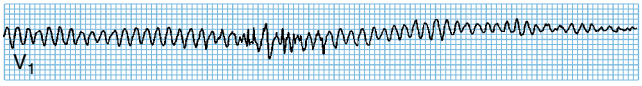

FIG. E1 Ventricular fibrillation. This rhythm strip shows ventricular fibrillation that degenerates further into fine ventricular fibrillation. (From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

- Diagnostic coronary angiography (rule out ischemic etiology).
- Cardiac MRI is indicated if the previous tests are unable to establish the cause of the arrhythmia and to rule out cardiomyopathies such as cardiac sarcoidosis, amyloid, LV noncompaction, arrhythmogenic right ventricular dysplasia.

Rx TREATMENT

ACUTE GENERAL Rx

- Patients with VF are hemodynamically unstable and require emergent unsynchronized defibrillation along with appropriate high-quality CPR as per ACLS protocols.
- Antiarrhythmic therapy with IV amiodarone and/or IV lidocaine is appropriate, particularly if patients have more than one event. IV lidocaine is particularly effective if VF is mediated by cardiac ischemia. Cardiac catheterization is recommended provided no contraindications exist. IV beta blockers are also recommended provided the patient is not in shock and blood pressure is permissive. If the patient is unresponsive after appropriate CPR a hypothermia protocol should be considered to aid in neurologic recovery. If the patient is having multiple episodes of VF despite these measures and is still awake between episodes, sedation and intubation are appropriate to reduce adrenergic drive. Cardiac electrophysiology consultation is appropriate for management of VF.
- Electrolyte supplementation is essential if hypokalemia or hypomagnesemia is detected.

CHRONIC Rx

After acute stabilization has occurred, chronic treatment is dependent on circumstances surrounding VF. If VF occurred within 48 hr of a large MI, then relief of ischemia via PCI, CABG, or lytic therapy is the primary treatment. A patient who has a well-defined ischemic trigger that has been satisfactorily treated likely will not require an implantable cardiac defibrillator, but a wearable external defibrillator could be considered under certain circumstances. Patients with VF in the periinfarction period who survive to hospital discharge have a prognosis similar to patients without arrhythmias in the peri-infarction period. ICD implantation is recommended in patients when there is no clearly reversible trigger, such as acute MI, commotio cordis, or drug overdose. If an inherited ion channelopathy is suspected, such as long QT, Brugada syndrome, or CPVT, genetic testing should be performed, but an ICD is appropriate even before definitive diagnosis is made for secondary prevention of sudden death from VF. If the etiology of VF is unknown after standard workup, cardiac MRI is suggested to work up cardiac sarcoid, hypertrophic cardiomyopathy, arrhythmogenic right ventricular cardiomyopathy. If indicated, then cardiac MRI should be done before ICD implantation. If a patient is subsequently diagnosed with inherited arrhythmia syndrome, familial screening should be discussed with the patient.

Cardiac echocardiography plays an important role in long-term risk stratification as well. If a patient's EF remains <35% 3 mo after appropriate revascularization and institution of appropriate heart failure therapy (ACE, beta-blocker therapy), then consideration of ICD is appropriate at that time.

Chronic therapy with antiarrhythmic medications such as amiodarone, mexiletine, or sotalol may be needed even after ICD implantation if the patient presents with multiple appropriate shocks. Continued focus on the trigger of VF such as ischemia or electrolyte disturbance is also critical. Cardiac ablation has been described in rare cases if a distinct triggering PVC is isolated, but this is not as commonly employed as ablation for VT.

DISPOSITION

Patients with sustained VF should be managed in an ICU because of the risk of degeneration to a hemodynamically unstable rhythm. A cardiologist or cardiac electrophysiologist should be consulted.

REFERRAL

All patients with VF should be referred to a cardiologist or a cardiac electrophysiologist.

PEARLS & CONSIDERATIONS

COMMENTS

- Effective VF treatment is strongly dependent on identifying and treating the inciting trigger (i.e., ischemia, cardiogenic shock) while using antiarrhythmic therapy IV amiodarone +/- IV lidocaine for stabilization.
- Hypothermia protocol should be considered in patients who have return of spontaneous circulation after VF arrest who remain comatose upon presentation or who were sedated prior to return of spontaneous circulation.
- ICDs are indicated for secondary prevention of VF independent of the substrate in the absence of a clearly reversible trigger.
- In the peri-infarction period, VT, particularly VT occurring more than 48 hr after MI, is far more predictive of subsequent out-of-hospital sudden death than VF and as such often warrants earlier ICD therapy consideration.
- In managing patients with multiple VF events (VF storm), therapies to reduce adrenergic drive are important, such as IV beta blockers as BP tolerates, aggressive IV sedation with propofol or Versed, or fentanyl along with intubation and electrolyte repletion.
- In patients with suspected long QT or Brugada syndrome, VF storm may be managed differently than VF in an ischemic setting or with structural cardiomyopathy. Long QT syndrome VF storm may prompt use of isoproterenol, magnesium repletion, and consideration of atrial pacing to prevent bradycardia. In treating Brugada syndrome VF storm, use of isoproterenol, quinidine and treatment of fever if it exists can be helpful.

PATIENT & FAMILY EDUCATION

Patients with familial or genetic causes of ventricular arrhythmias should have family screening of first-degree relatives.

BASIC INFORMATION

DEFINITION

- *Ventricular septal defect* (VSD) refers to an abnormal communication through the septum that separates the right and left ventricles of the heart.
- VSDs may be large or small, single or multiple.
- VSDs can be classified according to their anatomic location:
  1. Perimembranous (75% to 80%): This is the most common type of defect. The septal leaflet of the tricuspid valve may become adherent and form a "pouch" of the septum that can limit the left-to-right shunting and lead to self-closure.
  2. Muscular/trabecular (5% to 20%): This defect is entirely surrounded by muscular tissue. Often has less hemodynamic impact, and spontaneous closure is common.
  3. Inlet (8%): Immediately inferior to atrioventricular valve apparatus. This defect commonly lies beneath the septal leaflet of the tricuspid valve; associated with Down syndrome.
  4. Outlet (5%): Includes doubly committed juxtaarterial, supracristal, subpulmonary, and infundibular. This is the least common type of defect. Lies beneath the semilunar valves and is usually found beneath the aortic valve, and it may lead to aortic regurgitation. High prevalence in Asian population, and spontaneous closure is uncommon.

SYNONYM

VSD

ICD-10CM CODES

Q21.0	Ventricular septal defect
I23.2	Ventricular septal defect as current complication following acute myocardial infarction

EPIDEMIOLOGY & DEMOGRAPHICS

- VSDs are one of the most common congenital heart abnormalities.
- VSD accounts for ~25% of all congenital heart defects in children and for approximately 10% of defects in adults (the decrease is a result of spontaneous closure that occurs by adulthood, with the majority occurring prior to 3 yr of age).
- The prevalence of VSD is 3 to 4 infants per 1000 live births and 0.5/1000 adults.
- VSD is found with equal frequency among both males and females.
- VSD may be associated with the following conditions:
  1. Atrial septal defect (35%)
  2. Patent ductus arteriosus (22%)
  3. Coarctation of the aorta (17%)
  4. Subvalvular aortic stenosis (4%)
  5. Subpulmonic stenosis, usually associated with progressive aortic regurgitation caused by prolapse of the aortic cusp through the defect
- Multiple VSDs are more prevalent among patients with tetralogy of Fallot and double-outlet right ventricular defects.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical presentation depends on the direction and volume of the VSD shunt, which is dictated by the size of the defect as well as by the relative resistances of pulmonary and systemic vascular beds. Fig. E1 illustrates the physiology of VSD.
  1. Defects of ≤25% of the aortic annulus diameter are small or restrictive defects (Q_p:Q_s <1.5:1). These typically involve small left-to-right shunts, no left ventricular volume overload, and no pulmonary artery hypertension (PAH).
  2. Defects that are 25% to 75% of aortic annulus diameter are considered to be moderate in size. Small to moderate left-to-right shunting (Q_p:Q_s 1.5 to 2:1), mild to moderate left ventricular volume overload, and mild or no PAH are seen. Patients may have symptoms of congestive heart failure that may improve with medical therapy or with age as the defect decreases in size relative to increasing body size.
  3. Defects of ≥75% of the aortic annulus diameter usually have moderate to large left-to-right shunting (Q_p:Q_s >2:1), left ventricular volume overload, and PAH. These patients usually have a history of congestive heart failure, or they may possibly develop right-to-left shunting (Q_p:Q_s <1:1) in the setting of Eisenmenger syndrome during late childhood, adolescence, or young adulthood. Eisenmenger syndrome—resulting from chronic elevations of pressure and flow—is associated with functional and structural alterations within the pulmonary vasculature.
- Infants may be asymptomatic at birth because of elevated pulmonary artery resistance. During the first few wk of life, pulmonary arterial resistance decreases, thereby allowing for more left-to-right shunting through the VSD. This results in a subsequent increase in flow into the lungs, the left atrium, and the left ventricle, which can potentially cause left ventricular volume overload. Tachypnea, failure to thrive, and congestive heart failure may then ensue.
- In adults with VSD, the shunt is left to right in the absence of pulmonary stenosis and pulmonary hypertension. Patients typically manifest symptoms of left-sided heart failure from left ventricular volume overload and associated eccentric hypertrophy (e.g., shortness of breath, orthopnea, dyspnea on exertion). Presence of relevant longstanding PAH could ultimately lead to right-ventricular hypertrophy and dilation.
- A spectrum of physical findings may be seen, including the following:
  1. Machine-like holosystolic murmur that is heard best along the left sternal border
  2. Murmur becomes shorter as right heart pressures increase
  3. Systolic thrill
  4. Mid-diastolic rumble heard at the apex (increased mitral flow)
  5. S3 heart sound
  6. Rales
- With the development of pulmonary hypertension, the following occur:
  1. An augmented pulmonic component of the S2 heart sound and decrescendo diastolic murmur indicating pulmonary regurgitation
  2. Cyanosis, clubbing, right ventricular heave, and signs of right heart failure (i.e., as seen with Eisenmenger complex, with a reversal of the shunt in a right-to-left direction)

ETIOLOGY

- VSD is usually congenital but can be acquired.
- Acquired VSD may result from myocardial infarction, procedural complication (postsurgical residual leak, aortic valve replacement, septal myectomy, or alcohol ablation for hypertrophic cardiomyopathy), severe endocarditis, or trauma.
- Postinfarct ventricular septal defect (PIVSD) typically occurs 1 to 5 days after the event in 0.2% of patients in the current fibrinolytic or primary angioplasty era.

DIAGNOSIS

The diagnosis of VSD can be suspected during a physical examination. Imaging studies—particularly transthoracic echocardiography with color Doppler—establish the diagnosis.

DIFFERENTIAL DIAGNOSIS

On the basis of the physical examination alone, the diagnosis of VSD may be confused with other causes of systolic murmurs, such as mitral regurgitation, tricuspid regurgitation, aortic stenosis, pulmonary stenosis, and hypertrophic cardiomyopathy.

WORKUP

Any person who is suspected of having a VSD should undergo an ECG, a chest radiograph, and an echocardiogram.

LABORATORY TESTS

- Laboratory tests are not specific.
- The CBC may show polycythemia, especially in patients with Eisenmenger complex.
- Arterial blood gas results may demonstrate hypoxemia, which does not correct with supplemental oxygen.

IMAGING STUDIES

- ECG findings vary in accordance with the size of the VSD and depending on whether pulmonary hypertension is present. Volume loading of the left ventricle might result in left-ventricular hypertrophy and left atrial enlargement, whereas raised right-ventricular pressure due to either pulmonary hypertension or obstruction to the pulmonary

outflow tract could lead to right-ventricular hypertrophy findings.
- Chest x-ray findings in patients with VSD include the following:
  1. Cardiomegaly that results from left ventricular volume overload that directly relates to the magnitude of the shunt
  2. The enlargement of the proximal pulmonary arteries along with the redistribution and pruning of the distal pulmonary vessels as a result of sustained pulmonary hypertension (Fig. E2, *A*)
- Echocardiography is the imaging modality of choice for the diagnosis of VSD:
  1. Two-dimensional echocardiography and color Doppler display the size and location of the VSD (Fig. E2, *B*), the chamber sizes, ventricular function, the presence of aortic valve prolapse or regurgitation, outflow tract obstruction, and the presence of tricuspid regurgitation.
  2. Continuous-wave Doppler approximates the gradient between the left and right ventricles and estimates the pulmonary artery pressure.
  3. The magnitude of the shunt can be determined by the calculation of the pulmonary-to-systemic flow ratio with the use of echocardiography.
- Heart catheterization is primarily indicated to assess operability of VSD patients with PAH based on their pulmonary vascular resistance (PVR) and in patients in whom the noninvasive testing was inconclusive, and further information, such as quantification of shunting and assessment of pulmonary pressures, is required.
- MRI, computed tomography or (3D) transesophageal echocardiography can be useful to assess the pulmonary artery, the pulmonary vein, and the aortic anatomy and to confirm the anatomy of unusual VSDs (e.g., inlet or apical defects) that are inadequately visualized with conventional surface echocardiography.

Rx TREATMENT

The decision to close a VSD depends on the type, size, and shunt severity as well as the patient's pulmonary vascular resistance, functional capacity, and associated valvular abnormalities.

NONPHARMACOLOGIC THERAPY

- Patients with a small VSD with a large left-to-right ventricular pressure gradient, a pulmonary-to-systemic blood flow ratio (Q_p:Q_s) of less than 1.5:1, no evidence of pulmonary hypertension (i.e., restrictive defect), and absence of associated infective endocarditis or valvular regurgitation can be observed.
- Oxygen for hypoxemia and a low-salt diet are recommended for patients with congestive heart failure.

ACUTE GENERAL & CHRONIC Rx

Closure of the VSD is indicated for the following patients:

- Infants with congestive heart failure and failure to thrive. Unrestrictive VSDs require surgical intervention within the first 2 yr of life to prevent PAH.
- Children between the ages of 1 and 6 yr with persistent VSD and a Q_p:Q_s of ≥2.
- Adults with a Q_p:Q_s of ≥1.5, clinical evidence of left-ventricular volume overload, and with pulmonary artery pressure that is less than two thirds of the systemic pressure and pulmonary vascular resistance that is less than two thirds of the systemic vascular resistance (class I, level of evidence B).
- Worsening aortic regurgitation caused by VSD (class II_a, level of evidence C).
- Positive history of infective endocarditis (IE) (class II_B, level of evidence C).
- Surgical closure is not indicated for VSD with severe irreversible PAH with high PVR (pulmonary artery systolic pressure greater than two thirds systemic pressure or pulmonary vascular resistance greater than two-thirds systemic) (class III, level of evidence C). In this population, pharmacotherapy with bosentan (class I) or combination with phosphodiester type-5 inhibitors can be considered.

Surgical closure with Dacron or Gore-Tex patches or primary surgical closure has long been the gold standard of therapy. It has low operative mortality (<2%) at experienced centers. However, surgery still carries a small risk of complete heart block, postpericardiotomy syndrome, wound infection, and neurologic sequelae related to cardiopulmonary bypass. The transcatheter approach to VSD closure is becoming an increasingly accepted modality of treatment for appropriately selected patients. Some studies have shown similar success rates for both surgical and percutaneous closures, and there are significantly fewer complications, days in the hospital, and blood transfusions after percutaneous closures. For patients with difficult vascular access, a periventricular approach using a partial median sternotomy allows for a less invasive repair, often without cardiopulmonary bypass.

Catheter-based closure in muscular VSD may be considered, especially if the VSD is remote from the tricuspid valve and the aorta. Device closure is indicated in residual defects after prior attempts at surgical closure, restrictive VSDs with either a significant left-to-right shunt (Q_p:Q_s >1.5:1) or history of IE, trauma, or iatrogenic artifacts after surgical replacement of the aortic valve.

Surgery still remains the treatment of choice in patients with large defects, coexistent congenital anomalies requiring surgical correction, and defects with close proximity to the aortic valve. Subpulmonic VSDs may require surgery due to the increased risk of aortic valve prolapse. Perimembranous VSD with more than trivial aortic regurgitation should be referred to surgery. Availability of early reperfusion therapy has led to a decline in incidence of postinfarct VSDs (PIVSDs). Surgical closure remains the gold standard in the acute setting or for large (>15 mm) septal ruptures. In the subacute or chronic setting, small or medium PIVSD (<15 mm) can be treated with percutaneous closure with comparable mortality to surgery. Percutaneous closure may also be considered as a temporizing measure to clinically stabilize patients prior to surgical correction. PIVSDs generally arise within 3 to 5 days of the acute event, and even earlier following reperfusion therapy. PIVSDs usually carry a high mortality rate of ~95% of those treated medically and ~50% with surgical repair. Surgical management within 10 days has better outcomes than waiting for cardiac stabilization.

DISPOSITION

- The natural history of an isolated VSD depends on the type of defect, its size, and any associated abnormalities.
- Approximately 75% to 80% of small VSDs close spontaneously by the time the patient reaches the age of 10 yr.
- Only 10% to 15% of large VSDs will close spontaneously.
- Large VSDs that are left untreated may lead to arrhythmias, congestive heart failure, PAH, and Eisenmenger complex.
- Eisenmenger complex carries a poor prognosis, with most patients dying before the age of 40 yr.
- Issues to monitor in adults with unrepaired or repaired and catheter-closed VSDs include the following:
  1. Development of aortic regurgitation
  2. Assessment of associated coronary artery disease
  3. Development of tricuspid regurgitation
  4. Assessment of the degree of left-to-right shunting (in unrepaired or residual VSD after repair)
  5. Ventricular dysfunction
  6. Assessment of pulmonary pressure
  7. Development of subpulmonary stenosis (usually as a result of midcavity obstruction of the right ventricle due to hypertrophy of muscle bands, also referred to as a double-chambered right ventricle)
  8. Development of discrete subaortic stenosis
  9. Development of arrhythmia or heart block
  10. Thromboembolic complications
  11. Infective endocarditis
- After closure, late survival is excellent when ventricular function is normal. PAH may improve, progress, or remain the same. Late operations may be required for tricuspid or aortic regurgitation.

REFERRAL

All infants and children diagnosed with VSD should be referred to a pediatric cardiologist. Adults with VSD should be referred to an adult cardiologist. Cardiothoracic surgeons who have experience with congenital heart disease surgery should be consulted if surgery is indicated.

FOLLOW-UP

- Adults with no residual VSD, no associated lesions, and normal pulmonary artery pressure do not require continued follow-up at a regional adult congenital heart disease (ACHD) center.

- Adults with VSD with residual heart failure, shunts, PAH, AR, or RV outflow tract (RVOT) or LV outflow tract (LVOT) obstruction should be seen at least annually at an ACHD regional center (class I, level of evidence C).
- Adults with a small residual VSD and no other lesions should be seen every 3 to 5 yr at an ACHD regional center (class I, level of evidence C).
- Adults with device closure of a VSD should be followed up every 1 to 2 yr at an ACHD center depending on the location of the VSD and other factors (class I, level of evidence C).
- Patients who develop bifascicular block or transient trifascicular block after VSD closure are at risk in later yrs for the development of complete heart block and should be followed up yearly by history and ECG and have periodic ambulatory monitoring and/or exercise testing.

PEARLS & CONSIDERATIONS

COMMENTS

- A loud murmur does not imply a large VSD. Small, hemodynamically insignificant VSDs can cause loud murmurs.
- In patients with Eisenmenger complex, the right-to-left shunting across the VSD is usually not associated with an audible murmur.
- Air-eliminating filters should be used on intravenous lines to prevent air embolism in patients with cyanosis indicating right-to-left shunting.
- The risk of patients with unrepaired VSD developing infective endocarditis is 4%. The risk is higher if aortic insufficiency is present.
- For patients with endocarditis, routine antibiotic prophylaxis for dental or surgical procedures is not indicated for isolated VSDs, except in the following circumstances:
  1. In the presence of complex congenital heart disease with cyanosis
  2. In the presence of a residual VSD after surgical closure
  3. During the first 6 mo after surgical patch or percutaneous transcatheter closure
- Any patient with a newly diagnosed murmur or hemodynamic compromise after a myocardial infarction should undergo evaluation for possible VSD.
- Pregnancy with a VSD is generally well tolerated in women with small VSDs, no pulmonary artery hypertension, and no associated lesions. Women with large shunts may experience arrhythmias, ventricular dysfunction, and the progression of pulmonary hypertension.
- Women with VSDs and severe pulmonary artery hypertension or Eisenmenger physiology should be counseled against pregnancy because of associated excessive maternal and fetal mortality.

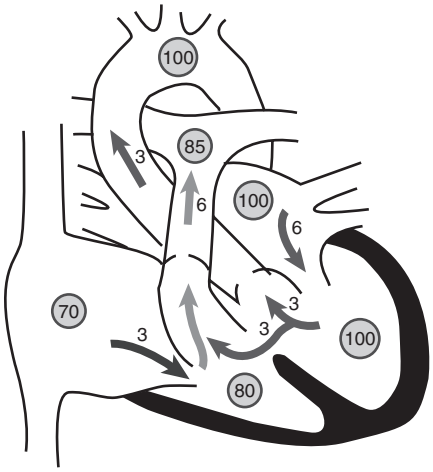

FIG. E1 Physiology of a large ventricular septal defect (VSD). Circled numbers represent oxygen saturation values. The numbers next to the arrows represent volumes of blood flow (in L/min/m^2). This illustration shows a hypothetical patient with a pulmonary-to-systemic blood flow ratio (Q_p:Q_s) of 2:1. Desaturated blood enters the right atrium from the vena cava at a volume of 3 L/min/m^2 and flows across the tricuspid valve. An additional 3 L of blood shunts left to right across the VSD, the result being an increase in oxygen saturation in the right ventricle. 6 L of blood is ejected into the lungs. Pulmonary arterial saturation may be further increased because of incomplete mixing at right ventricular level. 6 L returns to the left atrium, crosses the mitral valve, and causes a mid-diastolic flow rumble. 3 L of this volume shunts left to right across the VSD, and 3 L is ejected into the ascending aorta (normal cardiac output). (From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.)

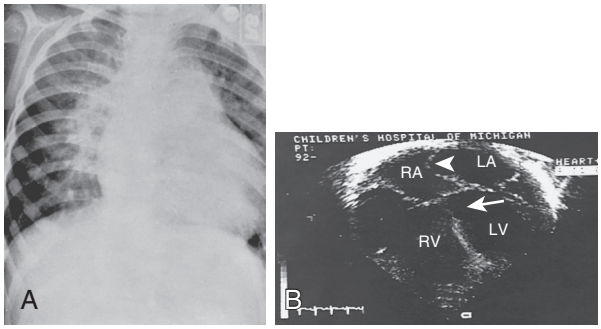

FIG. E2 A, Chest roentgenogram of a child with a large ventricular septal defect, large pulmonary blood flow, and pulmonary hypertension but only mild elevation of peripheral vascular resistance. This is reflected in the evidence of left and right ventricular enlargement, the enlargement of the main pulmonary artery, and a marked increase in pulmonary blood flow. **B,** Apical four-chamber echocardiographic view of ventricular septal defect (large arrow). The small arrow points to the interatrial septum. *LA,* Left atrium; *LV,* left ventricle; *RA,* right atrium; *RV,* right ventricle. **(A,** From Pacifico AD et al: Surgical treatment of ventricular septal defect. Ventricular Tachycardia

BASIC INFORMATION

DEFINITION

- Ventricular tachycardia (VT) can be classified based on time (duration) or morphology.
- Nonsustained ventricular tachycardia (NSVT) is defined as beats originating from the ventricle, lasting from 3 to 30 seconds or for <30 seconds, at a rate >100/min.
- Sustained ventricular tachycardia is defined as above but lasts >30 seconds or produces symptoms in the patient and/or requires early intervention due to hemodynamic embarrassment.
- Ventricular tachycardia can be monomorphic or polymorphic, and the etiology, significance, and treatment of these two types of VT are different.

SYNONYMS

VT
Nonsustained paroxysmal ventricular tachycardia (NSVT) (Fig. E1)
Sustained ventricular tachycardia
Ventricular tachycardia, monomorphic
Ventricular tachycardia, nonsustained
Ventricular tachycardia, paroxysmal
Ventricular tachycardia, polymorphic
Ventricular tachycardia, sustained

ICD-10CM CODE
I47.2 Ventricular tachycardia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The actual incidence and prevalence of VT in the general population is unknown. VT, especially NSVT, can be seen in both structurally normal and abnormal hearts, although it is far more common in the latter. In apparently healthy, asymptomatic individuals, the incidence is estimated at 0% to 3%. The prevalence of ventricular arrhythmias is approximately 12 per 10,000 persons under age 55 and increased to between 20 (females) and 59 (males) per 10,000 persons ≥65 yr of age.

For details on incidence of NSVT in various cardiac conditions, please refer to Table E1.

RISK FACTORS: The presence of structural heart disease is a strong risk factor for VT, but there are multiple, specific types of VT seen in patients without any structural heart disease. Coronary heart disease is responsible for the majority of cases of VT.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients may be asymptomatic, or they may present with any combination of palpitations, dizziness, syncope, chest pain, shortness of breath, seizures, or even cardiac arrest.
- History of structural heart disease, especially coronary artery disease and a prior myocardial infarction, is a strong predictor of VT. Patients may also have a history of pacemaker or defibrillator implantation. A family history of sudden death must also be sought.
- Physical findings of AV dissociation may be seen by the astute observer. These include cannon A waves in the neck and variability in intensity of heart sounds. Marked fluctuations in the blood pressure because of the variability in the degree of left atrial contribution to left ventricular filling and cardiac output.
- The patient may also present physical findings of congestive heart failure including an S3 gallop, pedal edema, or crackles at the lung bases.

Fig. E2 shows initiation and termination of VT by means of programmed ventricular stimulation.

ETIOLOGY

Sustained monomorphic VT (Fig. E3) is mostly caused by reentry around a scar in the ventricular wall. The scar is most commonly the result of an old myocardial infarction, but arrhythmogenic RV cardiomyopathy (ARVC), nonischemic dilated cardiomyopathy, sarcoidosis, Chagas disease, tuberculosis, surgical incisions for repair of congenital heart disease, and ventricular volume reduction surgery can all cause scars in the myocardium. Fibrosis in the scar creates areas of anatomical conduction block, and fibrosis between surviving myocytes reduces cell-to-cell coupling, thereby distorting the path of propagation and causing areas of slow conduction, which promotes reentry.

Monomorphic VT can also be seen in patients without any evidence of structural heart disease (idiopathic VT). This subgroup represents 10% of all patients with VT and includes right ventricular outflow tract (RVOT) VT, which is due to triggered activity and is sensitive to adenosine; paroxysmal sustained VT, which is sometimes considered a variant of RVOT VT; and idiopathic left ventricular tachycardia, which originates from the posterior septum with underlying mechanism of reentry and is sensitive to verapamil.

Polymorphic VT is usually the result of active myocardial ischemia, electrolyte abnormalities (hypokalemia, hypomagnesemia), or genetic conditions such as LQTS, BRS, and CPVT. It may also be seen in HCM, various types of nonischemic cardiomyopathy, and idiopathic VF. The mechanisms are poorly understood but likely involve an initiating trigger that interacts with multiple rotors in the substrate to maintain the arrhythmia. Conditions that can cause polymorphic VT/VF in the absence of structural heart disease are summarized in Table E2.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis of an ECG suspicious of VT includes:

- SVT with aberrancy, either with a preexisting bundle branch block or a rate-related bundle branch block
- SVT in a patient taking anti-arrhythmic drugs, e.g., IA or IC agents
- Antidromic tachycardia from ventricular preexcitation
- Ventricular paced rhythms
- ECG artifact

Differentiating sustained VT from other causes of wide complex tachycardia may be difficult, particularly if a high-quality 12-lead ECG is not available during the time of the arrhythmia. Stepwise criteria favoring VT in patients with wide-complex tachycardias using different algorithms are summarized in Table E3.

The following ECG characteristics strongly favor VT as opposed to SVT: Northwest (right superior) axis, QRS width >160 ms, AV dissociation fusion beats, and capture beats. The last three are highly specific for VT. The ECG hallmark for the diagnosis of VT is a wide complex tachycardia with the obvious presence of AV dissociation.

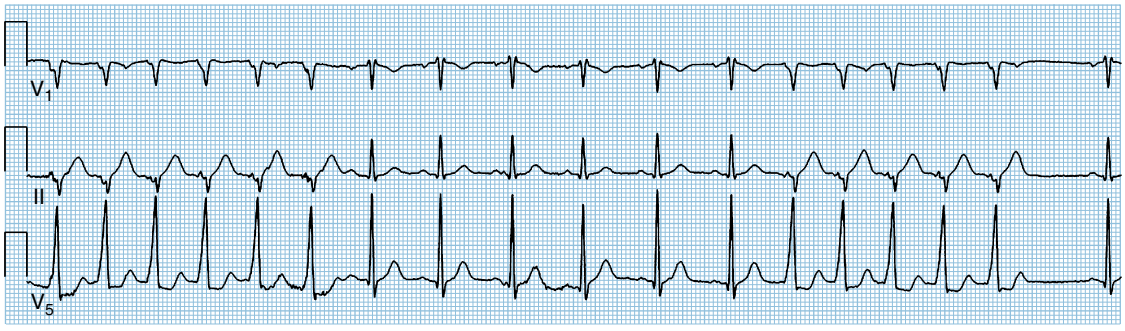

FIG. E1 Nonsustained ventricular tachycardia. This lead *V1, II,* and *V5* rhythm strip shows repetitive runs of nonsustained wide QRS complex tachycardias (five to six beats long, rate ~125 to 135 bpm) that represent nonsustained ventricular tachycardia. The second run is followed by a compensatory pause. There is atrioventricular dissociation evident in the first run on lead V1. (From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

TABLE E1 Reported Prevalence of Nonsustained Ventricular Tachycardia in Different Cardiac Conditions

Condition	Prevalence
Apparently healthy individuals	0%-3%
Non-ST ACS (2 to 9 days after admission)	18%-25%
Acute MI (early phase)	45%-75%
Reperfused acute MI (later than 1 week)	7%-13%
Heart failure (LVEF <30-40%)	30%-80%
DCM	40%-50%
HCM	25%-80%
Significant valve disease	≤25%
Hypertension	8%
Hypertension and left ventricular hypertrophy	12%-28%

DCM, Dilated cardiomyopathy; *HCM,* hypertrophic cardiomyopathy; *LVEF,* left ventricular ejection fraction; *MI,* myocardial infarction; *Non-ST ACS,* non–ST-segment elevation acute coronary syndrome.
From Saksena S et al: *Electrophysiological disorders of the heart,* ed 2, Philadelphia, 2011, Saunders.

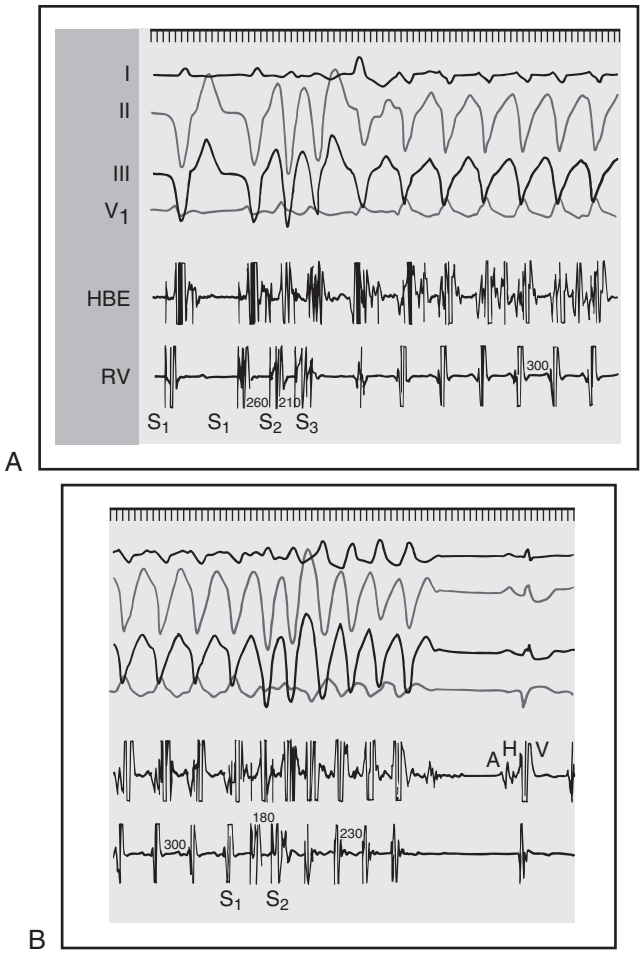

FIG. E2 Initiation and termination of ventricular tachycardia (VT) by means of programmed ventricular stimulation. The last two ventricular paced beats at a cycle length of 600 milliseconds are shown in **A.** A premature stimulus *(S2)* at an *S1-S2* interval of 260 milliseconds and another premature stimulus *(S3)* at a cycle length of 210 milliseconds initiate a sustained monomorphic VT at a cycle length of 300 milliseconds. **B,** Two premature ventricular stimuli *(S1-S2)* create an unstable VT that persists for several beats at a shorter cycle length (230 milliseconds) and then terminates, followed by sinus rhythm. *HBE,* His bundle electrogram; *RV,* right ventricle. (From Bonow RO et al: *Heart disease,* ed 9. Philadelphia, 2012, Saunders.)

Additional assessment is based upon QRS morphology. Most VT can be classified as either RBBB-type (overall positive in V1) or LBBB-type (overall negative in V1). The following criteria favoring VT can be applied for the respective types:

- RBBB type: Monophasic R; notched waveform with a taller left peak Rr'; biphasic RS or QR pattern.
- LBBB type in V1: R-wave >30 ms, slurred or notched S wave downstroke, delayed S nadir (QRS onset to S nadir >60 ms).
- RBBB-type tachycardias V6 shows QRS onset to predominant peak or nadir in lead V6 of 70 ms or rS pattern (R-to-S <1).
- LBBB type, criteria in V6: VT is favored in presence of a Q wave in v6.
- aVR: Presence of an initial R-wave in AVR and width of an initial r or q wave >40 ms.

WORKUP

- Lab testing should especially focus on checking K and Mg levels.
- A full 12-lead ECG of the tachycardia should always be obtained, whenever possible, and compared to the ECG in sinus rhythm if there is any uncertainty about the diagnosis. The electrocardiographic pattern of idiopathic VT by anatomic location is summarized in Table E4.
- This should be followed by an echocardiogram and ischemia evaluation with diagnostic coronary angiography and/or nuclear stress testing. Exercise testing should be performed because it may aid in provoking as well as establishing patient response to exercise-induced arrhythmias, including catecholaminergic *polymorphic* VT.
- An MRI of the heart is indicated if these tests are unable to establish the cause of the arrhythmia.
- Ambulatory ECG, event monitors, and implantable recorders are appropriate to evaluate for QT interval changes and T-wave alternans, judge therapy, evaluate risk, and to allow for symptom-rhythm correlation.
- Electrophysiologic testing is useful for the inducibility of VT, to guide ablation, the evaluation of drug effects, the assessment of the risk of recurrent VT, the loss of consciousness with arrhythmia as a suspected cause, and the assessment of indications for ICD therapy.

LABORATORY TESTS

- Potassium, magnesium
- Genetic testing should be reserved for specific situations, i.e., when there is a concern for genetically mediated conditions such as LQTS, HCM, CPVT, or BRS

IMAGING STUDIES

An echocardiogram and ischemia evaluation with diagnostic coronary angiography and/or nuclear stress testing is recommended to

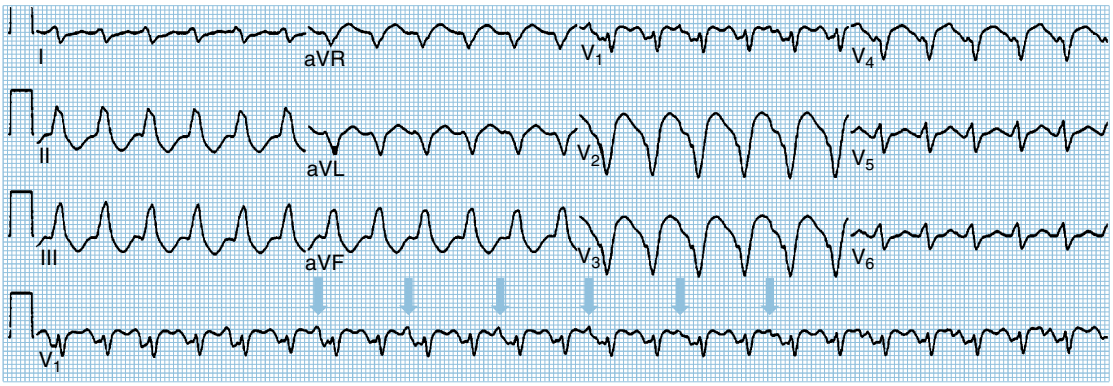

FIG. E3 Sustained monomorphic ventricular tachycardia. (From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

TABLE E2 Conditions That Can Cause Polymorphic VT/VF in the Absence of Structural Heart Disease and Potential Therapies

Clues	Test to Consider	Diagnoses	Therapies
Long QT/T-wave alternans	ECG/monitor	Congenital LQTS	Beta-blockers/stellatectomy
TdP pattern	Epinephrine challenge		Avoid QT-prolonging drugs
History of seizures	Genetic testing		Mexilitine/flecainide (LTQ3)
Specific trigger (loud noise)			Pacemaker/ICD
Long QT/T-wave alternans	ECG/Monitor	Acquired LQTS	Mg^{2+}/K^{+}
TdP pattern			Stop offending drug
Renal failure			Temporary pacing
New medication or drug abuse			
AV block	ECG/monitor	Bradycardia	Pacemaker
Incomplete RBBB with STE in leads V1 and V2	ECG	Brugada syndrome	Isoproterenol/quinidine
Fever	Drug challenge Genetic testing		Antipyretic Ablation ICD
Monomorphic PVC trigger	ECG/Monitor	Focal PVC origin	Ablation/ICD
J-point elevation	ECG	Early repolarization	ICD
Ventricular preexcitation	ECG	WPW	Ablation
Short QT interval	ECG	Short QTS	ICD
Bidirectional VT pattern exercise-induced	Digoxin level Exercise test Genetic testing	CPVT Andersen-Tawil syndrome Digoxin toxicity	Stop digoxin Beta-blockers/CCBs/flecainide ICD
STE and chest pain	Proactive testing	Coronary spasm	Vasodilators/coronary stent ICD
Short-coupled PVC trigger	ECG/Monitor	Idiopathic	ICD

CCBs, Calcium channel blockers; *CPVT,* catecholaminergic polymorphic ventricular tachycardia; *ECG,* electrocardiogram; *ICD,* implantable cardioverter-defibrillator; K^{+}, potassium ion; *LQTS,* long QT syndrome; Mg^{2+}, magnesium ion; *PVC,* premature ventricular complex; *RBBB,* right bundle branch block; *short QTS,* short QT syndrome; *STE,* ST elevation; *TdP,* torsade de pointes; *VT,* ventricular tachycardia; *WPW,* Wolff-Parkinson-White (syndrome).

rule out structural heart disease and ischemia. An MRI of the heart is indicated if these tests are unable to establish the cause of the arrhythmia, to rule out cardiomyopathies such as cardiac sarcoidosis, amyloid, LV noncompaction, arrhythmogenic right ventricular dysplasia, etc.

Rx TREATMENT

ACUTE GENERAL Rx

The initial management of a patient with VT depends on the hemodynamic stability of the patient. Emergent management is required in unstable patients, while additional time may be spent determining the etiology and treating any underlying precipitating factors in patients who are hemodynamically stable. All patients with VT should have a brief immediate assessment of the symptoms, vital signs, and level of consciousness to determine if they are hemodynamically stable or unstable. In unstable patients emergent synchronized cardioversion (or defibrillation for polymorphic rhythms) is needed. Those who subsequently become pulseless or unresponsive should be managed as per standard ACLS resuscitation protocols. An approach to nonsustained tachycardia is described in Fig. E4 and Table E5. Table E6 and Fig. E5 illustrate the management of sustained ventricular tachycardia.

If the patient is hemodynamically stable, either IV amiodarone, lidocaine (especially if there is a suspicion of ongoing ischemia), or procainamide may be used. In the case of a patient with sustained monomorphic VT and a known structurally normal heart, IV beta blockers or calcium blockers may be used. It must be remembered that use of all these agents may be associated with hemodynamic deterioration and an external defibrillator must be made available at all times.

Electrolyte supplementation is essential if hypokalemia or hypomagnesemia is detected.

TABLE E3 Stepwise Criteria Favoring Ventricular Tachycardia in Patients with Wide-Complex Tachycardias Using Different Algorithms

Kindwall Criteria[†]	Wellens Criteria[‡]	Brugada Criteria[§]	Miller Criteria[‖]
R >30 msec in V1 or V2 → VT	AV dissociation → VT	Absence of RS complex in all precordial leads → VT	Initial R wave in aVR → VT
Any Q in V6 → VT	QRS width >140 msec → VT	Longest R/S interval >100 msec in any precordial lead → VT	aVR with initial r or q >40 msec in duration → VT
>60 msec to S wave nadir in V1 or V2 → VT	Left axis deviation >−30 degrees → VT	AV dissociation → VT	aVR with a notch on the descending limb of a negative-onset and predominantly negative QRS in aVR → VT
Notched downstroke S wave in V1 or V2 → VT	If RBBB morphology, monophasic or biphasic QRS in V1 → SVT or R-to-S ratio of <1 in V6 → VT	If RBBB morphology, monophasic R or qR in V1 → VT R taller than R′ → VT rS in V6 → VT	In aVR, mV of initial 40 msec divided by terminal 40 msec ($v_i/v_t \leq 1$) → VT
	If LBBB morphology, S in V1-V2 → VT	If LBBB morphology, initial R >40 msec in duration → VT Slurred or notched S in V1 or V2 → VT Beginning Q or QS in V6 → VT	

LBBB, Left bundle branch block; *RBBB,* right bundle branch block; *VT,* ventricular tachycardia.

CHRONIC Rx

Chronic therapy of patients with VT usually requires multiple therapeutic modalities, including the ICD, antiarrhythmic drugs, catheter ablation, and surgery. An implantable cardioverter-defibrillator (ICD) is indicated for all patients who survive monomorphic VT in the setting of structural heart disease or prior MI, since it indicates the presence of a scar and risk of subsequent arrhythmias. Patients with idiopathic VT and structurally normal hearts generally do not require an ICD, but in cases of syncope associated with VT that cannot be successfully treated with ablation, it may be considered. Management of hemodynamically stable VT in patients with prior MI and normal LVEF remains under debate, but there is a consensus of considering VT ablation as initial therapy before ICD placement. For polymorphic VT, a reversible cause such as ischemia or electrolyte disturbances can sometimes be found, and an ICD may not be appropriate under these circumstances.

Chronic therapy with antiarrhythmic medications such as amiodarone, mexiletine, or sotalol may be needed even after ICD implantation if the patient presents with multiple appropriate shocks. No antiarrhythmic drug has shown mortality benefit in patients with monomorphic VT except beta-blockers. Use of antiarrhythmic medications is thus limited as an adjunct to catheter ablation in patients who cannot receive an ICD or in patients with frequent arrhythmia and ICD shocks. Catheter ablation of VT, particularly if performed early after first appropriate ICD discharge, is also very effective in preventing further ICD discharges and is associated with improved acute and long-term outcomes. For patients with refractory VT, surgical cardiac sympathetic denervation may be beneficial.

DISPOSITION

Patients with sustained VT, either monomorphic or polymorphic, should always be managed in an intensive care unit due to the risk of degeneration to a hemodynamically unstable rhythm. An electrophysiologist should be consulted.

REFERRAL

All patients with VT or NSVT should be referred to a cardiologist or a cardiac electrophysiologist.

PEARLS & CONSIDERATIONS

COMMENTS

- Use of antiarrhythmic drugs, especially IC agents, to treat NSVT is associated with increased mortality (CAST trial), while beta blockers have been shown to be helpful.
- In patients with coronary disease, NSVT has not been shown to have an adverse significance if LVEF is >40%. If the EF is below 40%, the MUSTT trial showed a benefit of EP-guided ICD therapy over antiarrhythmic agents such as mexiletine, propafenone, sotalol, or amiodarone. Patients with LVEF <35% are candidates for prophylactic ICD implantation based on the MADIT II and SCDHeFt trials.
- In hypertrophic cardiomyopathy, NSVT does seem to confer an increased risk of sudden death, especially if symptomatic, prolonged, or repetitive.
- There are certain conditions in which NSVT does not seem to have an adverse significance and does not predict sudden cardiac death. These include nonischemic dilated cardiomyopathy, mitral valve prolapse, mitral regurgitation, and absence of structural heart disease.

PATIENT & FAMILY EDUCATION

Patients with familial or genetic causes of ventricular tachycardia should have family screening of first-degree relatives.

AUTHOR: **Rizwan Khan, MD**

TABLE E4 Electrocardiographic Pattern of Idiopathic Ventricular Tachycardia (VT) by Anatomic Location

Location	ECG Pattern
Outflow Tract VT	LBBB morphology and inferior axis
Right ventricular outflow tract (RVOT)	Later precordial transition (V3 or later) Narrower R wave duration and lower R/S wave amplitude ratio in V1 and V2
Left ventricular outflow tract (LVOT)	Early precordial transition (by V_3) Earlier precordial transition than SR Broader R wave duration and greater R/S wave amplitude ratio in V1 and V2 Notch (qrS) in V1 or V2
Left aortic cusp	"M" or "W" pattern in V1 Monophasic R by V1/V2 Greater R wave II/III ratio Lead I QS or rS
Right aortic cusp	Monophasic R by V2/V3 Positive notched R-wave in lead I
Aortomitral continuity	qR in lead V1 Positive concordance across precordium Rs/rs complex in lead I R wave ratio <1 in II/III
Epicardial	MDI >55% QS in lead I QS in leads II, III, and aVF (if superiorly directed, near MCV) Q-wave ratio in aVL/aVR >1.4 or S wave amplitude >1.2 mV "Transition break," specifically a loss of R from leads V1 to V2 (QS or rS) with prominent R by V3 (suggests near anterior interventricular vein)
Pulmonary artery	Tall R wave in the inferior leads Larger Q wave ratio in aVL/aVR Larger R/S amplitude in lead V2 Larger Q wave ratio in aVL/aVR Larger R/S amplitude in lead V2
Tricuspid annular	LBBB morphology and inferior or superior axis R wave in lead I R or r with overall positive polarity in aVL Later precordial transition (>V3)
Tricuspid inflow or parahisian	LBBB morphology and inferior axis Large R wave in lead I R wave with flat/positive polarity or "w" pattern in aVL
Mitral annular (MA)	RBBB pattern with concordance in leads V1 to V6 Anterior MAVT: positive QRS polarity in leads II, III, and aVF and negative QRS polarity in leads I and aVL Posterior or posteroseptal MAVT: negative QRS polarity in leads II, III, and aVF and positive QRS polarity in leads I and aVL
Fascicular VT	
Left posterior fascicle	RBBB and left axis deviation (LAFB pattern) rsR′ in V1 q in I and aVL Narrow QRS ≤140 msec
Left anterior fascicle	RBBB and right axis deviation (LPFB pattern) Narrow QRS <140 msec
Left septal	Incomplete RBBB (QRSd ~100-110 msec) and normal axis
Papillary Muscle VT	RBBB; can have varied axes
Posterior papillary muscle	qR or R in V1 Absent Q in leads I and aVL
Anterior papillary muscle	qR or R in V1 rS in leads I and aVL
Crux VT	Leftward-superior axis QRS Delayed intrinsicoid deflection Basal crux: LBBB pattern with early precordial transition Apical crux: midprecordial transition with QS in V5/V6

LBBB, Left bundle branch block; *RBBB*, right bundle branch block.

TABLE E5 Management of Nonsustained Monomorphic and Polymorphic Ventricular Tachycardia

Setting	Therapy	Comments
Normal LV function	• No symptoms, no heart disease: No therapy • Young patient with bidirectional (or polymorphic) VT that may be life-threatening (CPVT): beta-adrenergic blocker • Symptoms of palpitations, no heart disease: beta-adrenergic blocker (e.g., acebutolol, 200-800 per day) • Idiopathic LV fascicular tachycardia (RBBB left axis QRS morphology): Verapamil • If LBBB (inferior axis morphology), beta-adrenergic blocker is first line. Other drugs: Sotalol (started in hospital), propafenone, flecainide, amiodarone. • RF ablation is curative for this type of VT in more than 95% if it can be initiated and mapped in the EP laboratory. • CAD, no symptoms: beta-adrenergic blocker, no additional antiarrhythmic therapy • CAD with symptoms, beta-adrenergic blocker, sotalol, amiodarone (started in the hospital) • Polymorphic NSVT 1. In the setting of long QT with syncope, treatment is required. 2. Genotyping is available. 3. Beta-adrenergic blockers are the first choice for long QT type I. 4. ICD is indicated for LQT2 or LQT3 with syncope or family history of sudden death	• Multiple clinical scenarios exist depending on the age of patient, heart disease, and symptoms. • If symptoms persist despite beta-adrenergic blockers or if they are not tolerated, nondihydropyridine calcium channel blockers can be utilized. • Idiopathic VT may occur in repetitive monomorphic variety and be symptomatic. 1. Not life-threatening. 2. Is exacerbated by exercise, mental stress, and catecholamines. • Idiopathic polymorphic VT in the young can be potentially life-threatening. 1. Treat with beta-adrenergic blocker. 2. Consider genotyping for CPVT. • Consider RV cardiomyopathy (dysplasia) with LBBB/noninferior axis morphology. • Consider ischemia. • The 12-lead morphology is helpful. 1. If LBBB with inferior axis, it is likely from the RV or LV/aortic cusp outflow tract in normal hearts and is ablatable. 2. If QRS is negative in I and aVL, it may be arising from the septum. 3. If it is positive in I and aVL, it may be arising from the free wall and may be adenosine sensitive. 4. VTs may respond to beta-adrenergic blockers, verapamil, and most antiarrhythmic drugs. • If it is a RBBB left axis QRS pattern, it may be a reentrant idiopathic VT from the LV apical septum. 1. Thought to be due to fascicular reentry. 2. Can be cured with RF ablation. 3. Is sensitive to verapamil (only use if known to be this type of VT). • Even patients with normal hearts may be at slightly higher risk for CA compared with the general population, but further evaluation and therapy is not beneficial. • Polymorphic tachycardia may be due to ischemia or infarction and may be transient.

TABLE E5 Management of Nonsustained Monomorphic and Polymorphic Ventricular Tachycardia

Setting	Therapy	Comments
Ischemic cardiomyopathy	• For LVEF ≤30%, 40 days after MI or 3 months after revascularization, ICD implantation is indicated for primary prevention • For LVEF ≤35%, NYHA FC II-III, ICD implantation is recommended for primary prevention • For LVEF ≤40%, EP study is recommended, and if sustained VT is induced, ICD should be implanted. • For NYHA FC II-ambulatory IV heart failure, LVEF ≤35%, LBBB and QRS duration ≥130 ms, cardiac resynchronization therapy is recommended after optimal medical therapy for at least 3 months or 40 days after MI.	• Increased risk of sudden death. • Increased risk is not related to length of episodes. • EP testing may risk stratify.
Nonischemic cardiomyopathy	• Beta-adrenergic blockers, ACE inhibitors, and other goal-directed medical therapy for heart failure. • For LVEF ≤35%, NYHA FC II-III, ICD is recommended. • For NYHA FC III-IV heart failure, LVEF ≤35%, and QRS duration >120 ms, cardiac resynchronization therapy is recommended.	
HCM	• Beta-adrenergic blocker, especially if symptomatic • Memory loop event recorders may be beneficial in correlating symptoms with arrhythmias. • No indication for amiodarone or other antiarrhythmic drugs if asymptomatic • Start amiodarone, if symptomatic, in the hospital. • ICD if 1. Septum >30 mm 2. Syncope 3. NSVT 4. Family history of sudden death 5. High-risk genotype 6. If prior CA 7. Sustained VT/VF 8. LV apical aneurysm 9. End-stage HCM with LVEF <50%	• Potentially indicative of a malignant, life-threatening ventricular arrhythmia. • EP testing of no proven benefit in this setting.
MI	• No specific therapy • Assess LV function. • Beta-adrenergic blocker as part of the post-MI regimen • If continued NSVT and impaired LV function (LVEF < 40%) after 4-6 wk, consider ICD and suppressive antiarrhythmic therapy to slow VT rate and prevent shocks.	• Little prognostic meaning early after MI. Predictive value increases with increasing time from MI. • If polymorphic, consider ischemia (or electrolyte disturbance if the QT interval is prolonged). • May represent a coronary reperfusion injury rhythm.
Preoperative	• If noncardiac surgery planned, assess symptoms, longevity of the problem, drugs • If recent onset: Assess LV function • If LVEF ≤40%, and if CAD, consider EP study. • If no CHF LVEF ≤ 30%, ICD. If CHF and LVEF ≤ 35%, ICD	
Postoperative	• No therapy • Has little prognostic meaning early after surgery • Resolves spontaneously in the great majority • Evaluate for underlying heart disease if risk factors are present. • Plan follow-up Holter monitor. If episodes continue, consider EP study. If induced VT, consider ICD if LVEF ≤ 40% or other criteria met (ischemic, nonischemic cardiomyopathy; discussed previously). • If asymptomatic, treat based on monitor results or based on EP study results.

TABLE E6 Management of Sustained Ventricular Tachycardia

Setting	Therapy	Comments
Acute therapy • Monomorphic VT well tolerated (patient awake and alert, no angina, no CHF, stable BP)	• First line: Amiodarone 150 mg over 10 min followed by 1mg/min for 6 h followed by 0.5 mg/min 1. May combine amiodarone IV with oral drug and with IV lidocaine if needed 2. Lidocaine 1.5-2 mg/kg (but only effective in <15%) • Second line: Procainamide 10-15 mg/kg at 25 mg/min (or less), assessing the BP carefully 1. Procainamide can slow VT and may be effective in an additional 20% to 30% 2. Amiodarone is probably more effective than procainamide, safer, and better tolerated • Third line: Cardioversion after adequate anesthesia • Do not cardiovert while awake • Fourth line: Antitachycardia pacing via a temporary transvenous pacing lead	• Assess cause and hemodynamic tolerance. 1. Guidance of therapy is dependent on the clinical status of the patient. 2. VT can always degenerate to VF even if it is at first stable. • IV amiodarone is emerging as first-line therapy for sustained monomorphic VT due to lack of efficacy of other drugs. • Procainamide has a negative inotropic effect. • Temporary transvenous pacing requires time and experienced personnel to accomplish.
Acute therapy, MI	• Same as above but degree of urgency in treatment is greater. • The length of time in VT, even if apparently tolerated, should be minimized. • Lidocaine is associated with no improvement in mortality.	• Monomorphic VT 1. May not increase long-term mortality. 2. Can be ischemia induced but this is rare (<3% of all MIs). 3. Tends to indicate "an electrical reentry circuit" of damaged myocardium.
Acute therapy, polymorphic VT • Normal QT interval • Patient stable	• If stable and the patient is awake (very rare): 1. If ineffective, DC shock (200 J >300-360 J) after anesthetized • IV beta-adrenergic blockade as tolerated	• Very rare for patient to be stable and awake • Assess cause and hemodynamic tolerance. • Rule out ischemia, infarction, electrolyte abnormality (low K^+ or Mg^{2+}), or adverse drug effect. • Assess age, underlying disease process and LV function, potential causative factors (e.g., exercise). • Therapy depends on the clinical status, which can always degenerate to VF even if it appears to be stable. • IV amiodarone may be effective, but there are no data on well-tolerated polymorphic VT.
Chronic prevention No structural heart disease Idiopathic VT, usually in young patient Often exercise- or stress-induced Rule out RV cardiomyopathy (dysplasia) with MRI	• First line: beta-adrenergic blocker titrated to the highest tolerated dose • If recurrent episodes (with moderate or severe symptoms) occur: RF catheter ablation • The success for LBBB inferior axis and for RBBB superior axis VT ablation is 90% to 95% • RF ablation is first line if patient has syncope, hemodynamic intolerance, or patient preference	• Monomorphic VT can be highly symptomatic but is almost never "malignant" and life-threatening. • LBBB/inferior axis VT is usually from the outflow tract. 1. If the QRS is negative in I and aVL, suspect a septal or LV origin. 2. If it is positive in these leads, suspect a free wall origin. 3. The mechanism may be due to triggered automaticity. Highly amenable to RF ablation. • RBBB/superior axis VTs are likely due to reentry in the Purkinje system. 1. Are verapamil sensitive. 2. Can be successfully ablated. • For LBBB, noninferior axis morphology VTs, r/o ARVC.
Prior MI, ischemia can be provoked	• If monomorphic, suspect a substrate that is due to scar, not ischemia. • If polymorphic, suspect ischemia or infarction. • Consider a functional stress test or coronary angiogram and revascularization if ischemic. • ICD implantation if hemodynamically significant sustained VT/VF • Ablation can be successful in >50% but with a high rate of long-term recurrence 1. Used as adjunctive therapy to ICD implantation 2. May be used to reduce recurrent ICD shocks • Adjunctive antiarrhythmic drugs include amiodarone or sotalol	• May also be associated with VF. • Rarely, monomorphic VT is due to ischemia alone, but always suspect substrate even if episodes occur relatively soon after infarction. 1. If an antiarrhythmic drug is being used, consider the possibility of a proarrhythmic effect. • Most patients (>95%) with chronic VT due to CAD will be inducible in the EP laboratory, but this does not change treatment strategy.

Vertebral Compression Fractures

BASIC INFORMATION

DEFINITION

Vertebral compression fractures (VCFs) are defined as fractures of spinal vertebrae in which a bony surface is driven toward another bony surface. These fractures are classified as radiographic reductions in vertebral body height of more than 15%.

SYNONYMS

Thoracolumbar vertebral compression fractures
Osteoporotic fractures
VCF

ICD-10CM CODES

M80.0	Post-menopausal osteoporosis with pathologic fracture
M80.4	Drug-induced osteoporosis with pathological fracture
M80.5	Idiopathic osteoporosis with pathological fracture
M80.8	Other osteoporosis with pathological fracture
M80.9	Unspecified osteoporosis with pathological fracture
S32.009A	Unspecified fracture of unspecified lumbar vertebra, initial encounter for closed fracture
S22.009A	Unspecified fracture of unspecified thoracic vertebra, initial encounter for closed fracture

EPIDEMIOLOGY & DEMOGRAPHICS

Approximately 700,000 VCFs occur in the United States each yr, and they affect up to 25% of postmenopausal women. They are the most common complication of osteoporosis. The prevalence increases with age, reaching a peak of 40% to 50% among women aged >80 yr. Compression fractures are also a major concern among men, although their rates of VCF are lower.

RISK FACTORS:

- Modifiable: Tobacco or alcohol use, osteoporosis, estrogen deficiency (i.e., early menopause, bilateral oophorectomy, premenopausal amenorrhea for >1 yr), frailty, impaired vision, abusive situations, inadequate physical activity, low body mass index, and deficiency of vitamin D or calcium.
- Nonmodifiable: Advanced age, female gender, dementia, Caucasian descent, history of fractures in adulthood and among first-degree relatives, and falls.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Asymptomatic: Most VCFs are asymptomatic, except for height loss or kyphosis (i.e., dowager's hump [Fig. 1]), which is often a sign of multiple VCFs and height loss of >6 cm has a sensitivity/specificity of 94% and 30%, respectively, for VCF.
- Symptomatic: When symptomatic, VCFs usually present as acute back pain after activity (e.g., bending, lifting) or coughing; neck strain and radicular rib pain may also be present.

ETIOLOGY

- VCFs take place when the combination of bending and the axial load on the spine exceed the strength of the vertebral body.
- The primary etiology of VCF is osteoporosis, though a pathologic fracture from an underlying malignancy, typically metastatic disease, must be ruled out.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Osteoporosis
- Malignancy, most often metastases
- Hyperparathyroidism
- Osteomalacia
- Granulomatous diseases (e.g., tuberculosis)
- Hematologic/oncologic diseases (e.g., multiple myeloma, primary bone malignancy)

WORKUP

- Only one third of VCFs are diagnosed. Guidelines for patient selection for vertebral fractural assessment are described in Box 1.
- VCFs can be clinically suspected from the history and physical alone, though they are often diagnosed incidentally by imaging performed for another indication.
- There may or may not be a specific injury or a remembered event that led to the VCF.

LABORATORY TESTS

Tests to rule out infection or cancer may be helpful, such as a complete blood count, an erythrocyte sedimentation rate, an alkaline phosphatase level, and a C-reactive protein level; these tests can be reserved for individuals for whom there is clinical suspicion.

IMAGING STUDIES

- Plain frontal and lateral radiographs (x-rays) are the initial imaging method and may be sufficient, particularly when no neurologic abnormalities are present. MRI and computed tomography (CT) scans may be uncomfortable or painful for the patient, especially during the acute phase.
- Although CT scans are not routinely necessary for the diagnosis, they can be helpful for visualizing fractures that are not seen on plain films, for evaluating the integrity of the posterior vertebral wall, for ruling out other causes of back pain, for detecting spinal canal narrowing, and for assessing instability.
- MRI may be useful when spinal cord compression is suspected, if neurologic symptoms are present, or to distinguish malignancy from osteoporosis (e.g., in patients <55 yr with VCF after minimal or no trauma).
- Bone density studies may be helpful to determine the severity of osteoporosis, which is a key risk factor for future fractures.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Physical therapy.
- External back braces: Frequently recommended to relieve pain and improve mobility, however, controlled trials have not shown any effect in patients with vertebral compression fractures.
- Exercise programs: Getting active as soon as possible is extremely important for both short-and long-term recovery.

ACUTE GENERAL Rx

- Analgesics are first line for pain control, including acetaminophen and opioids (oral or parenteral), and pain can be expected to diminish over 4 to 6 wk.
- Nonsteroidal antiinflammatory drugs are helpful but must be used with caution among elderly patients or when contraindicated.
- Muscle relaxants should be used judiciously because they have significant side effects, particularly in the elderly.
- Intranasal calcitonin (200 units once daily, alternating nostrils) has been shown in some small trials to hasten relief from pain when used as an adjunct to oral analgesics, and a

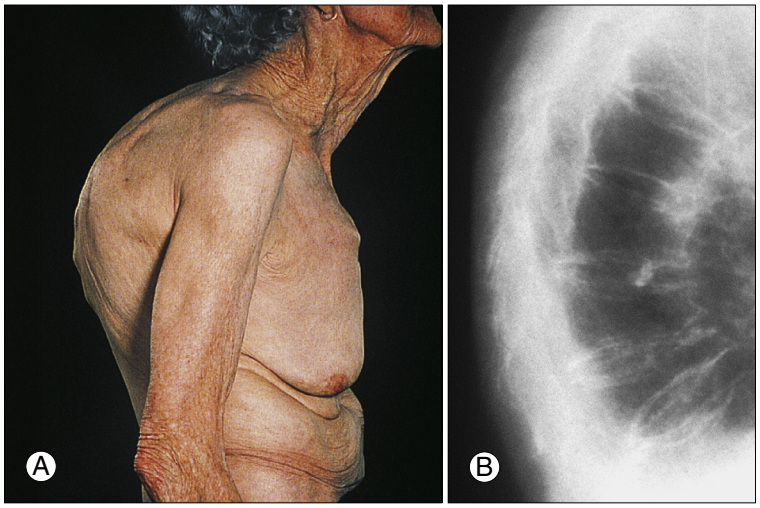

FIG. 1 Dowager's hump. (A) Marked thoracic kyphosis secondary to multiple osteoporotic fractures in an older woman. **(B)** Corresponding radiograph. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

BOX 1 2007 ISCD Guidelines for Patient Selection for Vertebral Fractural Assessment

- Postmenopausal women with low bone mass (osteopenia) by BMD criteria, *plus* any one of the following: age >70 yr, historical height loss >4 cm (1.6 in), or prospective height loss >2 cm (0.8 in), self-reported vertebral fracture (not previously documented)
- Two or more of the following: age 60 to 69 yr, self-reported prior non-vertebral fracture, historical height loss of 2 to 4 cm, or chronic systemic diseases associated with increased risk of vertebral fractures (e.g., moderate to severe COPD or COAD, seropositive rheumatoid arthritis, Crohn disease)
- Men with low bone mass (osteopenia) by BMD criteria, *plus* any one of the following: age >80 yr, historical height loss >6 cm (2.4 in), prospective height loss >3 cm (1.2 in), self-reported vertebral fracture (not previously documented)
- Two or more of the following: age 70 to 79 yr, self-reported prior non-vertebral fracture, historical height loss of 3 to 6 cm, on pharmacologic androgen deprivation therapy or following orchiectomy, chronic systemic diseases associated with increased risk of vertebral fractures (e.g., moderate to severe COPD or COAD, seropositive rheumatoid arthritis, Crohn disease)
- Women or men on chronic glucocorticoid therapy (equivalent to 5 mg or more of prednisone daily for 3 mo or longer)
- Postmenopausal women or men with osteoporosis by BMD criteria, if documentation of one or more vertebral fractures will alter clinical management

BMD, Bone mineral density; *COAD,* chronic obstructive airways disease; *COPD,* chronic obstructive pulmonary disease; *ISCD,* International Society for Clinical Densitometry.
Reproduced with permission from the International Society for Clinical Densitometry. From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.

2- to 4-wk course may be useful for patients who do not achieve adequate control with oral analgesics alone.

- Early mobilization with physical therapy is important for recovery and prevention of subsequent fractures.
- The efficacy of vertebroplasty versus kyphoplasty versus conservative treatment remains controversial.
- Percutaneous vertebroplasty involves the injection of acrylic bone cement into the affected vertebral body in an effort to stabilize the fracture and reduce pain, whereas in kyphoplasty, a high-pressure inflatable bone tamp or balloon is expanded within the body of the affected vertebra to restore prefracture vertebral height before the injection of bone cement. These two procedures were thought to be helpful in patients who did not respond to conservative therapy; however, further studies showed them to be no more effective than sham procedures (Buchbinder et al, 2009; Kallmes et al, 2009). Nonetheless, Klazen et al (2010) demonstrated in an open-label prospective randomized trial that for the subgroup of patients with acute osteoporotic VCFs and persistent pain, percutaneous vertebroplasty may provide immediate pain relief, sustained for at least a yr, which may be significantly greater than that achieved with conservative treatment. Zampini (2010) showed in a nonrandomized cohort study that elderly patients who underwent kyphoplasty were more likely to be discharged home. McCullough et al (2013) analyzed Medicare claims of patients with VCF treated with kyphoplasty or vertebroplasty compared with medical management and found no difference in mortality or major medical outcomes but decreased health care utilization in the conservatively managed group. These procedures are still in their infancy, and more answers should be forthcoming as to their efficacy, as well as questions regarding the amount of time that conservative therapy alone should be pursued and which procedure, if any, should be advised. Most current guidelines recommend 4 to 6 wk of medical therapy before pursuing surgical intervention in neurologically intact VCF.

CHRONIC Rx

Osteoporosis should be treated with the reduction of risk factors (e.g., smoking, alcohol), diet, exercise, calcium and vitamin D supplements, and with medications used to treat osteoporosis (e.g., bisphosphonates).

REFERRAL

Referral is indicated for neurologic abnormalities, unremitting pain, instability, continued disability, or when the investigation of the cause of the fracture reveals serious underlying pathology.

PEARLS & CONSIDERATIONS

Prevention of osteoporosis and conservative therapy remain the mainstay of treatment.

COMMENTS

- VCFs should be suspected in anyone aged >50 yr with the acute onset of low back pain. There are many opportunities for diagnosis and treatment that are easy to miss, especially for males.
- Solitary vertebral fractures higher than T7 are unusual and should raise suspicion for other pathologic causes.
- Diagnosing and treating osteoporosis reduce the incidence of VCFs.
- Getting people with VCF physically active as soon as possible will be efficacious both acutely and in the long term.
- In general, VCF will be best managed through a partnership of the patient, the primary care physician, an orthopedist, a physical therapist, a dietitian, and a social worker.

PREVENTION

Reducing the effects of modifiable risk factors is key.

Vestibular Neuronitis

BASIC INFORMATION

DEFINITION

Vestibular neuronitis is a syndrome of sudden-onset dysfunction of the peripheral vestibular system, often severe, with prolonged vertigo, nausea, and vomiting.

SYNONYMS

Vestibular neuritis
Acute neuritis
Neurolabyrinthitis
Vestibular neuropathy

ICD-10CM CODES

H81.2	Vestibular neuronitis
H81.23	Vestibular neuronitis, bilateral
H81.20	Vestibular neuronitis, unspecified ear
H81.21	Vestibular neuronitis, right ear
H81.22	Vestibular neuronitis, left ear

EPIDEMIOLOGY & DEMOGRAPHICS

Vestibular neuritis is the second most common cause of peripheral vestibular vertigo with an incidence of about 3.5:100,000 population. Although etiology remains uncertain, it is thought to result from viral infection causing selective inflammation of the vestibular nerve. Infectious origin is supported by the fact that it occurs in epidemics, may affect several family members, and occurs more commonly in spring and early summer. The male:female ratio is nearly 1:1. There is selective damage to the superior part of the vestibular labyrinth, supplied by the superior vestibular portion of the eighth cranial nerve.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Develops acutely over a period of hours and resolves over periods of days or wks, although long-term sequelae may occur, such as residual imbalance and nonspecific dizziness persisting for mos. Symptoms include sudden-onset, spontaneous, isolated vertigo; spontaneous peripheral nystagmus (horizontal and not direction changing); and imbalance. Patients report intense sensation of rotation and difficulty standing and walking and tend to veer toward the affected side; autonomic symptoms occur with pallor, sweating, nausea, and vomiting.

ETIOLOGY

Etiology remains uncertain but viral and post-viral inflammatory disorders are suspected. Herpes zoster, reactivation of herpes simplex type I, and other viruses have been implicated, but evidence is circumstantial.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cerebellar infarction
- Labyrinthitis: Similar symptoms of vertigo, with the addition of unilateral hearing loss
- Labyrinthine infarction
- Acoustic neuroma
- Perilymph fistula
- Migraine-associated vertigo
- Ménière disease
- Multiple sclerosis

WORKUP

- Patient may fall toward affected side when attempting ambulation or during Romberg tests.
- Hallpike maneuver: Checking for nystagmus and asking about re-creation of vertigo symptoms.
- Head-impulse test: Grasp patient's head, apply brief small-amplitude rapid head turn, first to one side and then the other; patient fixates on examiner's nose: positive test is lack of or slowing of corrective eye movements ("saccades") on affected side. A positive test supports the diagnosis of vestibular neuronitis.
- Laboratory testing and imaging are generally not indicated but may help rule out other etiologies.

LABORATORY TESTS

- Electronystagmography (ENG): A battery of eye movement tests that may provide an objective assessment of the vestibular and oculomotor systems and may help localize the lesion's site
- Audiogram: Normal

IMAGING STUDIES

Brain imaging: CT or MRI—normal

TREATMENT

NONPHARMACOLOGIC THERAPY

Vestibular exercises, when tolerated, will accelerate recovery.

ACUTE GENERAL Rx

Most treatments are empirical and related to symptoms. Further studies are needed.

- Corticosteroids: Corticosteroids are often prescribed, although a Cochrane review finds that there is insufficient evidence for administration. Some studies have shown that glucocorticoids administered within 3 days after onset of vestibular neuronitis may improve long-time recovery of vestibular function and reduce the length of hospital stay and may improve the caloric extent and recovery of canal paresis while others show no significant difference
- Antihistamines: e.g., meclizine, dimenhydrinate, promethazine
- Anticholinergics: Scopolamine
- Antiemetics: Droperidol, prochlorperazine
- Benzodiazepines: e.g., diazepam, valium, lorazepam
- Valacyclovir, either alone or in combination, is likely ineffective in treating vestibular neuronitis

CHRONIC Rx

- Vestibular rehabilitation exercises
- Anti-GABA agents
- Antihistamines

DISPOSITION

Most patients can be treated as outpatients, but inpatient care may be required in cases where vomiting is uncontrollable. If dehydrated because of severe vomiting, sufferers may require brief parenteral therapy.

REFERRAL

- ENT: If diagnosis uncertain, and if these patients are at risk for benign paroxysmal positional vertigo (BPPV) subsequently; also if symptoms linger
- Neurology: If question of central origin or migraine

PEARLS & CONSIDERATIONS

COMMENTS

- Diagnosis unlikely to be vestibular neuronitis if hearing is impaired or other neurologic signs and symptoms are present.
- Although patients may recover from dramatic acute symptoms, subtle vestibular deficits may linger for prolonged period, if not indefinitely (i.e., residual imbalance and nonspecific dizziness).
- Program of vestibular habituation head movement exercises can reduce imbalance symptoms.

Viral Bronchiolitis

BASIC INFORMATION

DEFINITION

Bronchiolitis is a common respiratory illness seen in children under 2 yr of age during the winter to early spring months. Most commonly caused by a viral infection, bronchiolitis often presents with fever, runny nose, cough, wheezing/crackles, and increased work of breathing. The upper respiratory illness leads to acute inflammation of the lower respiratory tract, causing increased mucus production, bronchospasms and edema, which impair air movement. The diagnosis of bronchiolitis is largely obtained through history and physical exam. The term bronchiolitis commonly has been associated with the first episode of wheezing within the first 12 mo of life. Most cases are self-limiting and rarely life-threatening.

ICD-10CM CODES

J11.1	Bronchiolitis due to influenza virus
J21	Acute bronchiolitis
J21.0	Acute bronchiolitis due to RSV
J21.1	Acute bronchiolitis due to human metapneumovirus
J21.8	Acute bronchiolitis due to other specified organisms
J44	Chronic bronchiolitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Approximately 20% of infants will need care for bronchiolitis in the first yr of life, and 2% to 3% of those younger than 12 mo will be hospitalized.

PEAK INCIDENCE: Bronchiolitis can occur throughout the yr but is most prevalent from December to March.

PREDOMINANT AGE & SEX:

- Children <2 yr old; it is most common in children 3 to 9 mo old due to their airways being smaller
- Affects both sexes equally

RISK FACTORS:

- Children under the age of 2 yr
- Children born prematurely
- Cardiopulmonary disease
- Formula feeding (those who are not breastfed)
- Children enrolled in day care
- Contact with an infected person
- Depressed immune system
- Cigarette smoke exposure

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Wheezing
- Rales (crackles)
- Cough
- Fever
- Rhinorrhea
- Nasal flaring, intercostal retractions
- Tachypnea
- Hypoxemia
- Apnea

ETIOLOGY

By far the most common cause of bronchiolitis is a viral infection. The following are the most common viruses that lead to bronchiolitis:

- Respiratory syncytial (50% to 80%)
- Rhinovirus (5% to 25%)
- Adenovirus (5% to 10%)
- Human metapneumovirus (5% to 10%)
- Parainfluenza virus (5% to 25%)
- Coronavirus (5% to 10%)
- Influenza virus and enterovirus (<5%)

Bronchiolitis in some cases has been caused by bacteria, such as *Mycoplasma pneumoniae*.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bronchitis
- Asthma
- Pneumonia
- Heart failure
- Croup

WORKUP

Diagnosis is based on symptoms, clinical presentation, patient's age, time of yr, and physical exam findings. Radiological and/or laboratory studies should not be obtained routinely. Clinical testing is used when the diagnosis of bronchiolitis is unclear or there is a need to risk stratify for complications. Table E1 describes a suggested assessment tool.

LABORATORY TESTS

- Routine lab testing for bronchiolitis is not recommended.
- For patients with concerns regarding severe bronchiolitis or alternative diagnoses, one can consider complete blood count, basic metabolic panel, arterial blood gas, and respiratory syncytial viral (RSV) testing.

IMAGING STUDIES

Although routine radiological studies are not recommended, a chest x-ray may have utility in evaluating for bacterial pneumonia or alternative diagnoses.

TREATMENT

The American Academy of Pediatrics recommends against the routine use of adjunct therapies such as albuterol, epinephrine, systemic corticosteroids, and antibiotics in the treatment of bronchiolitis. There may be a subset of patients who can benefit from adjunct therapies, especially when the diagnosis of bronchiolitis is unclear; however, the mainstay of bronchiolitis treatment is supportive.

NONPHARMACOLOGIC THERAPY

- Nasal bulb suction
- Bed rest
- Hydration
- Air humidifier

ACUTE GENERAL Rx

- Mild to moderate bronchiolitis:
  1. Tylenol and/or Motrin for fever
- Severe bronchiolitis:
  2. Supplemental oxygen for Sats <90
  3. Consider high-flow nasal cannula (HFNC), continuous positive airway pressure, and intubation for refractory hypoxia.
  4. IV or NG fluids for patients who cannot maintain oral hydration
  5. Nebulized hypertonic saline in hospitalized infants and children
  6. Antibiotics for patients with evidence of bacterial pneumonia
  7. Ribavirin in life-threatening disease or immunocompromised patients with documented RSV bronchiolitis

DISPOSITION

- Bronchiolitis symptoms peak around day 3 to day 5 and usually resolve completely within 3 weeks.
- Patients who are clinically stable, taking oral fluids, and maintaining oxygen saturation over 92% usually are considered appropriate to discharge. Ability of caretaker to care for the child, resources available, and access to follow-up should be considered for discharge.
- Clinicians should be aware of high-risk groups with bronchiolitis. These include infants with apnea, history of prematurity age <12 weeks, and chronic medical problems.
- Consider admission in patients with signs of respiratory distress, inability to keep saturation greater than 90% without oxygen, poor PO intake, apnea, cyanosis, and poor follow-up, and/or groups with higher risk of disease.

REFERRAL

The patient should follow up with the pediatrician within 24 hours of discharge for recheck.

PEARLS & CONSIDERATIONS

PREVENTION

- Hand hygiene
- Avoiding other young children with active viral respiratory illnesses
- Avoiding other young children with active viral respiratory illnesses
- Limit tobacco smoke exposure
- Breastfeeding

BASIC INFORMATION

- Vitamin D is a hormone and a steroid and, by definition, not a vitamin. There are two forms of vitamin D: vitamin D_2 and vitamin D_3.
- Vitamin D_2 (ergocalciferol) is mainly found in some plant foods.
- Vitamin D_3 (cholecalciferol) is produced in skin exposed to ultraviolet (UV) B radiation from sunlight (Fig. E1). Gloson, Whistler, and DeBoot independently described rickets in the mid-seventeenth century. Sniadecki first reported the association of rickets with inadequate exposure to sunlight in 1822.
- The major functions of vitamin D include:
  1. Increasing calcium and phosphorus absorption from the small intestines
  2. Promoting the maturation of osteoclast to resorb calcium from bones

DEFINITION

Vitamin D deficiency is characterized by hypocalcemia and/or hypophosphatemia leading to impaired bone mineralization. It is classified as a serum 25-hydroxyvitamin D (25[OH]D) level of <20 ng/ml (50 nmol/L).This standard definition of vitamin D deficiency has been recently challenged, and some endocrinologists recommend a cutoff of 12 mg/ml for vitamin D deficiency.[1] Vitamin D insufficiency is defined as a 25(OH)D between 12 and 20 ng/ml.

The consequences of vitamin D deficiency include:

- Bone disease (rickets, osteoporosis, low bone mass)
- May impair reproductive success
- Decrease the ability to combat infection (especially TB, influenza, viral infection)
- May induce or worsen autoimmune disorders
- May increase the incidence of death due to heart disease, IBD, fracture, and cancer of the breast, colon, and prostate
- Subclinical vitamin D deficiency may occur in developed countries and be associated with increased fall risk, possible fractures, and osteoporosis.

SYNONYMS

The sunshine vitamin
The antirachitic factor
Cholecalciferol

ICD-10CM CODE
E55.9 Vitamin D deficiency, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Vitamin D insufficiency is very high among older adults and hospitalized and institutionalized people.
- Worldwide deficiency and insufficiency affect about 1 billion people.
- Children and young adults: 40% to 50% of preadolescent Caucasian girls, and Hispanic and African American adolescents, are vitamin D deficient.

PEAK INCIDENCE: In the U.S., 40% to 100% of the elderly are vitamin D deficient. Sixty percent of nursing home residents may be vitamin D deficient.

PREVALENCE: Forty-two percent of African American girls and women 15 to 49 yr old have 25(OH)D levels <20 ng/dl.

PREDOMINANT SEX AND AGE:

- Decreased skin production of vitamin D with age
- Increased prevalence among darker-skinned individuals

RISK FACTORS:

- Age (due to decreased ability to produce D_3)
- Sunshine-deficient areas (geographic location, living in higher latitudes)
- Dark-skinned individuals (melanin competes with vitamin D_3 precursors for UV photons and thus decreases pre-D_3 formation)
- Obese individuals
- Institutionalized individuals
- Pregnant and lactating women
- Use of sunscreen (sun radiation that causes skin cancer also produces pre-vitamin D_3 in skin)
- Patients on certain medications that antagonize vitamin D action (phenobarbital, phenytoin)
- Intestinal resection
- Severe chronic liver diseases (such as cirrhosis)
- Kidney disease (e.g., nephritic syndrome)
- Sarcoidosis and lymphomas (increased catabolism of 25[OH]D to 1,25[OH]2D)
- Intestinal malabsorption disease (caused by celiac sprue, cystic fibrosis, Whipple disease)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical presentation of vitamin D deficiency is dependent on the duration and severity of deficiency.
- Most patients with mild to moderate vitamin D deficiency are asymptomatic.
- Severe deficiency may lead to rickets (in children), osteomalacia (in adults), bone demineralization, hypokalemia, and phosphaturia.
- Rickets–seen in children; caused by defective mineralization in the skeleton (Fig. E2).
  1. Bowing of the legs
  2. Leg bone pain
  3. Delayed growth
  4. Seizure due to hypocalcemia
- Osteomalacia—seen in adults
  1. Periosteal bone pain (best detected by putting firm pressure on tibia or sternal bones)
  2. Proximal muscle weakness
  3. Chronic muscle aches/pain
- Fracture with very minimal trauma (brittle and easily broken bones)
- Severe hypocalcemia—especially in late vitamin D deficiency leading to seizure tetany
- Hypophosphatemia
- Paresthesia
- Tetany
- Muscle cramps

ETIOLOGY

- Inadequate exposure to sunlight, such as:
  1. During winter
  2. In nursing home and health care institution residents
  3. With excessive use of sunscreen
- Medications: Individuals on certain medications, such as phenobarbital, phenytoin, and rifampin (antagonize vitamin D action/increase vitamin D catabolism)
- Diseases and disease states:
  1. Diseases causing vitamin D malabsorption:
     a. Cystic fibrosis
     b. Whipple disease
     c. Celiac sprue
  2. Diseases increasing vitamin D catabolism:
     a. Lymphoma
     b. Sarcoidosis
  3. Intestinal resection
  4. Decreased 25(OH)D production:
     a. Kidney disease
     b. Liver cirrhosis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Arthritis
- Fibromyalgia

WORKUP

- Population-wide screening for vitamin D deficiency is not recommended because evidence to support this practice is lacking.
- Screening is needed for individuals at risk (osteoporosis, history of falls, obese persons, pregnant and lactating women, diseases causing vitamin D malabsorption, African Americans). Workup involves blood and urine tests as well as radiography, as outlined in the next section.

LABORATORY TESTS (TABLE 1)

- Serum 25(OH)D: This is the best test to determine vitamin D status.
- Parathyroid hormone (PTH): Increased levels in vitamin D insufficiency. It is a marker of vitamin D insufficiency.
- Increased (serum or bone) alkaline phosphatase.
- Decreased 24-hour urine calcium (patient should not be on a thiazide).
- In patients at risk for osteomalacia [s-25(OH)D is less than 10 ng/ml], check Ca, Ph, alkaline phosphatase, PTH, basic metabolic panel, and tissue transglutaminase antibodies.

IMAGING STUDIES

- Radiographs may show:
  1. Pseudofractures of the pelvis, femur, metatarsals
  2. Nontraumatic fractures
- Bone density:
  1. Decreased bone mineral density (osteopenia or osteoporosis). Note that bone mineral density is not routinely performed

[1] Shah S et al: Serum 25-hydroxyvitamin D insufficiency in search of a bone disease, *J Clin Endocrinol Metab* 102:2321-2328, 2017.

in patients whose only risk factor is decreased Vitamin D levels.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Natural sources of vitamin D. These include:
  1. Exposure to sunlight. A mild sunburn is equivalent to consuming 10,000 to 25,000 IU of dietary vitamin D.
  2. Dietary sources are not enough to meet daily requirements. Oily fish such as salmon, cod, and mackerel are rich sources of vitamin D_3.
- Foods fortified with vitamin D.
  1. Mainly fortified dairy products.
  2. Fortified orange juice.

ACUTE GENERAL Rx

- Treating deficiency (general population): Cholecalciferol (vitamin D_3), when available, is preferred for vitamin D supplementation.
  1. 50,000 IU of vitamin D every week for 8 weeks, *or*
  2. 6000 IU daily to achieve a serum level of 25(OH)D of at least 30 ng/ml.
- Maintenance measures after treatment (general population): 1500 to 2000 IU daily.
- Treating deficiency (obese patients, patients with malabsorption syndromes, or those taking certain medications, as indicated earlier).
  1. 6000 to 10,000 IU daily.
- Maintenance measures after treatment (obese patients, patients with malabsorption syndromes, or those taking certain medications, as indicated earlier):
  1. 3000 to 6000 IU daily.
- After treating deficiency, recheck 25(OH)D in 12 to 16 weeks.

If deficiency persists after several attempts at treatment, try UV B light therapy

REFERRAL

Referral to an endocrinologist is recommended if there is no response to treatment.

PREVENTION

- Food fortification with vitamin D_2 or vitamin D_3.
- Adequate sun exposure, for example, exposure in the middle of the day (between 10:00 am and 3:00 pm).
- Use vitamin D_3 for supplementation when available.
- Vitamin D supplementation (per the Endocrine Society):
  1. Infants (age range 1 to 12 mo) require at least 400 IU/day of vitamin D
  2. Children (age range 1 to 18 yr) require 600 IU/day of vitamin D
  3. Adult supplementation (adults 19 to 70 yr): 600 IU of vitamin D daily
  4. Adult supplementation (persons ≥70 yr): 800 IU of vitamin D daily
  5. Exceptions: Pregnant or lactating women, obese persons, and patients on antiseizure medications, steroids, antifungals, and AIDS medications should be given 2× to 3× more vitamin D
  6. To reduce the risk of fracture and falls, the American Geriatric Society recommends a daily intake of at least 1000 IU and the National Osteoporosis Foundation 800 to 1000 IU in adults 65 yr or older

SCREENING: Routine screening for low-risk adults is not recommended. Screening is recommended only for individuals at high risk for vitamin D deficiency such as blacks and Hispanics, obese individuals (BMI >30 kg/m^2), patients with osteoporosis, the elderly, and patients with certain chronic diseases (see "Risk Factors"). According to the U.S. Preventive Services Task Force (USPSTF), current evidence is insufficient to assess the balance of benefits and harms of screening for vitamin D deficiency in asymptomatic adults.

PEARLS & CONSIDERATIONS

- In the U.S., vitamin D supplements are available by prescription as vitamin D_2 (ergocalciferol) or over the counter as vitamin D_3 (cholecalciferol, usually in 400- to 1000-IU doses). Both vitamin D_2 and vitamin D_3 are acceptable as supplements. On average, oral vitamin D_3 raises blood levels more than does vitamin D_2.
- Upper limit of maintenance tolerability in healthy adults is 4000 IU a day. More than 4000 IU of vitamin D daily in nondeficient individuals increases the risk of harm. High-level supplements (>10,000 IU daily) are associated with kidney and tissue damage.
- Vitamin D supplementation is recommended for fall prevention. High-dose vitamin D supplementation (≥800 IU daily) has been shown to be favorable in the prevention of hip fracture and any nonvertebral fracture in persons 65 yr of age or older.
- Prescribing more than the recommended daily amount to improve quality of life or prevent cardiovascular disease or death is not advised.
- Trials have shown that low vitamin D levels are associated with depressive symptoms, especially in persons with a history of depression. These findings suggest that measuring vitamin D levels may be useful in patients with a history of depression.
- Vitamin D supplementation, administered with calcium, has been shown to lower the risk for falling and improve muscle strength in the elderly, especially in older vitamin D-deficient women who are at high baseline risk for falling.
- The treatment of vitamin D insufficiency in asymptomatic persons might reduce mortality risk in institutionalized elderly persons and risks for falls but not fractures.
- Recent data suggest that vitamin D deficiency is associated with the risk of developing certain cancers (including breast, colon, and prostate).
- Vitamin D deficiency is associated with some autoimmune diseases (types 1 and 2 diabetes, metabolic syndrome, multiple sclerosis).

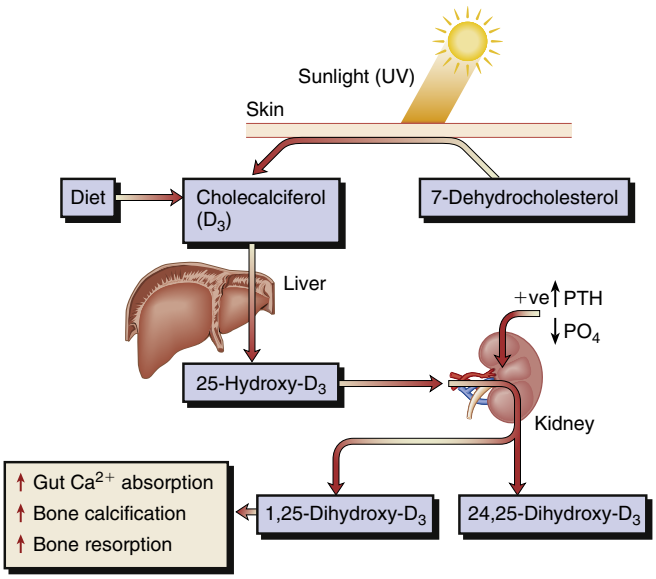

FIG. E1 The metabolism and actions of vitamin D. The primary source of vitamin D in humans is photoactivation in the skin of 7-dehydrocholesterol to cholecalciferol, which is then converted first in the liver to 25-hydroxyvitamin D and subsequently in the kidney to the much more active form, 1,25-dihydroxycholecalciferol ($1,25[OH]_2,D_3$). Regulation of the latter step is by parathyroid hormone *(PTH),* phosphate, and feedback inhibition by $1,25(OH)_2,D_3$. This step can also occur in lymphomatous and sarcoid tissue, resulting in the hypercalcemia that may complicate these diseases. BASIC INFORMATION

DEFINITION

Vitamins are organic compounds that cannot be synthesized by humans but are required as nutrients in minute amounts for normal metabolism. Vitamins have several different functions: They may regulate cell growth and differentiation, as catalysts, as antioxidants, and as co-enzymes. Vitamins are classified as either fat soluble (vitamins A, D, E, K) or water soluble (B group of vitamins and C). Deficiency of most vitamins is rare in Western countries. Certain groups may be prone to vitamin deficiency, and these are discussed here. Vitamin D deficiency is discussed in a separate topic.

SYNONYMS

Hypovitaminosis
Vitamin A: Retinol
Vitamin E: Alpha tocopherol
Vitamin K: Phytonadione or menadiol
Vitamin B_1: Thiamine
Vitamin B_2: Riboflavin
Niacin: Vitamin B_3; nicotinic acid
Vitamin B_5: Pantothenic acid
Vitamin B_6: Pyridoxine; pyridoxal phosphate
Folic acid: Vitamin B_9; folate
Vitamin B_{12}: Cyanocobalamin
Vitamin C: Ascorbic acid

ICD-10CM CODES

E50	Vitamin A deficiency
E51	Thiamine deficiency
E53	Deficiency of other B group vitamins
E55	Vitamin D deficiency
E56	Other vitamin deficiencies
E56.0	Deficiency of vitamin E
E56.1	Deficiency of vitamin K
E53.0	Riboflavin deficiency
E52	Niacin deficiency [pellagra]
E53.1	Pyridoxine deficiency
E53.8	Deficiency of other specified B group vitamins
E54	Ascorbic acid deficiency

EPIDEMIOLOGY & DEMOGRAPHICS

Deficiency can occur in all age groups but is most common in the elderly.

- Vitamin A deficiency: Affects 250 million preschool children worldwide.
- Vitamin K deficiency: Varies by geographic regions; no race predilection; affects both sexes equally. Encountered often in infants.
- Vitamin B_1 (thiamine) deficiency: Incidence is unknown; no sex, race, or age predilection.
- Vitamin B_2 (riboflavin): More common than previously appreciated. Deficiency is referred to as ariboflavinosis.
- Vitamin B_5 (pantothenic acid) deficiency: Rare, as it is present in all foods.
- Vitamin B_{12} (cobalamin) deficiency: Relatively common. Occurs in all age groups but more common in the elderly.
- Vitamin B_9 (folic acid) deficiency: Mandatory fortification started in 1998. Prevalence before fortification 16% and after 0.5%. Neural tube defect associated with low maternal folate status during pregnancy. Pregnant women and the elderly are at greatest risk of folic acid deficiency.
- Vitamin C (ascorbic acid) deficiency: Smokers and low-income persons are at increased risk.

Fig. 1 shows environmental and nutritional factors in disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Vitamin A: Xerophthalmia, xerosis of the cornea, keratomalacia, Bitot spots (abnormal squamous cell proliferation and keratinization of the conjunctiva), nyctalopia (poor adaptation to darkness)/night blindness, poor bone growth, dry skin and hair, follicular hyperkeratosis (caused by blockage of hair follicles by keratin), pruritus, broken fingernails
- Vitamin K: Clinical manifestation usually occurs if hypoprothrombinemia is present. Major symptom is bleeding to minor trauma. Also can show easy bruisability, epistaxis, hematoma, or gum bleeding
- Vitamin E: Nerve dysfunction (ataxia; hyporeflexia, peripheral neuropathy); bone weakness
- Vitamin B_1 (thiamine): Beriberi, which has two subtypes (infantile and adult). Adult type is described below:
  1. Dry beriberi (affecting the nervous system): Symmetrical peripheral neuropathy (with sensory and motor impairments), Wernicke encephalopathy (nystagmus, ataxia, ophthalmoplegia, and confusion), Korsakoff syndrome (impaired short-term memory loss and confabulation but normal cognition)
  2. Wet beriberi (affecting the cardiovascular system): Cardiomegaly, cardiomyopathy, heart failure, tachycardia, hypotension, chest pain, peripheral edema
  3. Gastrointestinal (GI): Anorexia; constipation
- Vitamin B_2 (riboflavin):
  1. Cheilosis (chapping and fissure of the lip)
  2. Glossitis (sore red tongue)
  3. Oily, scaly rashes on nasolabial folds, eyelids, scrotum, labia majora
  4. Red itchy eyes
  5. Normocytic or normochromic anemia
  6. Peripheral neuropathy
- Vitamin B_3 (niacin):
  1. Pellagra (4 *D*s—diarrhea, dermatitis, dementia, and ultimately death)
  2. Hyperpigmentation of sun-exposed skin
  3. "Raw beef" swollen and painful tongue
  4. Deficiency can be seen in prolonged use of Isoniazid, in carcinoid syndrome, and in Hartnup syndrome
- Vitamin B_5 (pantothenic acid):
  1. Deficiency is rare
  2. Deficiency leads to "burning feet syndrome" (distal paresthesia and dysesthesia)
  3. Anemia
  4. GI symptoms
- Vitamin B_6 (Pyridoxine): Rare to see overt deficiency.
  1. Mild deficiency—glossitis, cheilosis, impaired proprioception; sensory ataxia, confusion, depression
  2. Severe deficiency—seborrheic dermatitis, seizure, microcytic
- Vitamin B_{12} (cyanocobalamin):
  1. Megaloblastic anemia (pernicious anemia)
  2. Neurologic symptoms including peripheral neuropathy, ataxia (shuffling gait), paresthesia; subacute degeneration of the spinal cord (demyelination of the dorsal column), visual disturbances due to optic atrophy
  3. Glossitis and GI symptoms such as nausea, vomiting, and anorexia are also common
  4. Patients may also have dementia/mental sluggishness, depression, and weakness
- Vitamin B_9 (folic acid):
  1. Patchy hyperpigmentation of skin (especially between fingers and toes) and mucous membranes
  2. Moderate fever (temp <102° F; 38.9° C) despite the absence of infection
  3. Neural tube defect
  4. Angular stomatitis
  5. Red, beefy, smooth, and shiny tongue
  6. Megaloblastic anemia
- Vitamin C: Scurvy (bruising, petechiae, follicular hyperkeratosis, perifollicular hemorrhage), poor wound healing, fatigue, gingivitis/bleeding gums, weight loss, bone abnormalities (Fig. E2)

ETIOLOGY

- Fat-soluble vitamins (vitamins A, D, E, K):
  1. Decreased ingestion, malnutrition, eating disorders
  2. Diseases that affect fat absorption decrease the absorption of fat-soluble vitamins—for example, cystic fibrosis, celiac sprue, inflammatory bowel disease, cholestasis, hepatobiliary disease, small bowel surgery
  3. Change in vitamin metabolism:
     a. Alcoholism
     b. Drugs such as cholestyramine, warfarin, anticonvulsants, antibiotics (e.g., cephalosporins)
     c. Chronic kidney disease
- Increased risk in:
  1. Vegans
  2. Recent immigrants
  3. Refugees
  4. Toddlers/preschoolers living below the poverty line
- Water-soluble vitamins (the B group of vitamins and vitamin C)—there are several etiologic factors, including:
  1. Inadequate intake
  2. Decreased absorption
  3. Alcoholism
  4. Pregnancy/lactation
  5. Peritoneal dialysis
  6. Medications (e.g., isoniazid, phenothiazines, tricyclic antidepressants, metformin [vit B_{12}])
  7. Malabsorption
  8. Low income
  9. Advanced age
- Vitamin B_{12} deficiency—caused by:
  1. Insufficient dietary intake, as in strict vegans
  2. Decreased absorption secondary to intrinsic factor deficiency, decreased

Vitamin	Function	Consequences of deficiency
A	Retinal function, epithelial growth control	Night blindness, keratomalacia, xerophthalmia
B_1 (thiamine)	Co-enzyme	Beriberi, Wernicke's encephalopathy
B_2 (riboflavin)	Co-enzyme	Dermatitis, glossitis, keratitis, neuropathy, confusion
B_6 (pyridoxine)	Co-enzyme	Neuropathy
B_{12} (cobalamin)	Nucleic acid synthesis	Megaloblastic anemia Subacute combined degeneration of spinal cord
Niacin	Co-enzyme NAD, NADP	Pellagra (diarrhea, dermatitis, and dementia)
Folate	Co-enzyme in nucleic acid synthesis	Megaloblastic anemia, villous atrophy of gut
Vitamin C	Co-factor in hydroxylation	Scurvy
Vitamin D	Calcium and phosphate absorption	Rickets (childhood) Osteomalacia (adults)
Vitamin E	Antioxidant	Spinocerebellar degeneration
Vitamin K	Co-factor for coagulation factor synthesis	Bleeding due to coagulation defects

FIG. 1 Environmental and nutritional factors in disease. (From Stevens A: *Core pathology,* St Louis, 2009, Elsevier.)

intrinsic factor secretion, gastric atrophy, gastrectomy/gastric bypass
3. Terminal ileum disease such as celiac disease, enteritis, tropical sprue

- Folic acid deficiency:
1. Increased needs can lead to deficiency (e.g., pregnancy, lactation, malignancy)
2. Derangement of folate metabolism by:
   1. Medication (e.g., methotrexate)
   2. Disease (e.g., hypothyroidism)
   3. Increased excretion: As seen in alcoholics

DIAGNOSIS

WORKUP/LABORATORY TESTS

General initial laboratory tests include:
- Complete blood cell count (CBC)
- Liver function tests (LFTs)
- Basic metabolic panel (BMP)
- Albumin
- Measurement of serum levels of the specific vitamin in question

Specific tests may be considered in the following cases:
- Vitamin A:
1. Serum retinol level (best test, a direct measure, expensive)
2. Retinol binding protein (easier to perform, less expensive)
3. Dark-adaptation threshold test

- Vitamin K:
1. Prothrombin time/partial thromboplastin time (PT/PTT)
2. Prothrombin
3. Des-gamma-carboxyprothrombin (most sensitive test).
4. Niacin: Urine-*N*-methylnicotinamide (level <0.8 mg/day indicates niacin deficiency)

- Vitamin B_1 (thiamine):
1. Blood thiamine levels
2. Thiamine pyrophosphate levels in blood
3. Erythrocyte thiamine transketolase activity (ETKA)
4. Urinary thiamine excretion

- Vitamin B3 (niacin): Check urinary N-methylnicotinamide or erythrocyte NAD/NADP ratio (tests are not readily available)
- Vitamin B_2: Check plasma riboflavin concentration
- Vitamin B_{12}:
1. Serum vitamin B_{12} <190 pg/ml is diagnostic of vitamin B_{12} deficiency
2. Serum methylmalonic acid, which is elevated in B_{12} deficiency
3. Antiparietal antibody
4. Intrinsic factor antibody is decreased
5. Blood smear shows macrocytosis and hypersegmentation of megaloblasts
6. CBC shows increased mean corpuscle volume (MCV)
7. Megaloblastic anemia

- Folic acid:
1. Check serum folate level.
2. Additional testing includes checking for serum homocysteine level, which will be elevated.
3. Red cell folate level shows chronic folate status.

TREATMENT

Most of the vitamins are available over the counter individually or in different multivitamin formulations.
- Vitamin A deficiency: Treat with oral supplementation 10,000 IU daily.
1. Consume vitamin A–rich foods such as liver, beef, carrots, oranges, mangoes.
2. Five servings of fruit and vegetables give enough carotenoids for a day.

- Vitamin K deficiency: Treatment depends on the severity of bleeding, administered subcutaneously (SQ) or intramuscularly (IM).
- Vitamin B_1 (thiamine) deficiency: Give intramuscular thiamine 50 mg for several days.
1. If B_1 deficiency is suspected and patient needs intravenous glucose, give thiamine first before intravenous glucose. This prevents the development of Korsakoff psychosis.

- Vitamin B_{12} deficiency: Give 1000 mcg IM daily for 7 days, then once a wk for 1 mo, then once a mo indefinitely.
1. A potential option is oral supplementation.

- Folic acid deficiency: Daily requirement is 400 to 1000 mcg (1 mg) daily.
1. Centers for Disease Control and Prevention (CDC) recommend that women of childbearing age take 400 mcg of folic acid daily.

BASIC INFORMATION

DEFINITION

Vitiligo is the acquired loss of epidermal pigmentation that is characterized histologically by the absence of epidermal melanocytes. There are 6 types based on the extent and distribution of the involved areas: localized (single or few macules in one anatomic area), segmental, generalized, universal (entire body surface is depigmented), acrofacial (fingers, lips), and mucosal.

ICD-10CM CODE
L80 Vitiligo

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Vitiligo affects 0.5% to 1% of the population; it is the most common depigmenting disorder.
PREDOMINANT AGE: Vitiligo can begin at any age, but the age at onset is <20 yr for half of patients. Peak onset is between ages 10 and 30. Onset is usually earlier in females.
GENETICS: A positive family history is present in 25% to 30% of patients, and both sexes are equally affected. There are no differences in the rates of occurrence with regard to skin type or race; however, it occurs in more than 8% in some regions of India.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Hypopigmented and depigmented lesions (Fig. E1) favor sun-exposed regions, intertriginous areas, genitalia, and sites over bony prominences.
- Areas around the body orifices are also frequently involved.
- The lesions tend to be symmetric (Fig. E2).
- Segmental vitiligo (20% of childhood cases and 5% of adult cases) often has a dermatomal or quasidermatomal distribution.
- Vitiligo lesions may occur at trauma sites (i.e., Koebner phenomenon).
- The hair in affected areas may be white.
- The margins of the lesions are usually well demarcated; when a ring of hyperpigmentation is seen, the term *trichrome vitiligo* is used.
- The term *marginal inflammatory vitiligo* is used to describe lesions with raised borders.
- Initially the disease is limited, but the lesions tend to become more extensive over time.
- Focal vitiligo may affect nondermatomal areas (e.g., glans penis).
- Vitiligo may begin around pigmented nevi and produce a halo (i.e., Sutton nevus); in such cases, the central nevus often regresses and disappears over time.

ETIOLOGY & PATHOGENESIS

- Three pathophysiologic theories:
  1. Autoimmune theory (i.e., autoantibodies against melanocytes)
  2. Neural theory (i.e., neurochemical mediators selectively destroy melanocytes)
  3. Self-destructive process in which melanocytes fail to protect themselves against cytotoxic melanin precursors
- Although vitiligo is considered to be an acquired disease, 25% to 30% of cases are familial. The mode of transmission is unknown; the condition seems to be polygenic or autosomal dominant with incomplete penetrance and variable expression.
- Associated disorders:
  1. Alopecia areata
  2. Type 1 diabetes mellitus
  3. Adrenal insufficiency
  4. Hyperthyroidism and hypothyroidism

FIG. E1 Vitiligo. Depigmented, usually well-defined, white macules or patches that tend to have an oval or linear contour. (From Paller AS, Mancin AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E2 Vitiligo. Symmetrical depigmentation of the knees and lower extremities. The dorsal aspect of the feet and hands are particularly hard to repigment. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

5. Mucocutaneous candidiasis
6. Pernicious anemia
7. Polyglandular autoimmune syndromes
8. Melanoma
9. Iritis and retinal pigmentary abnormalities

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acquired hypopigmentation disorders:
  1. Chemical-induced (e.g., chloroquine, imatinib, phenolic-catecholic derivatives [e.g., adhesives, deodorants, latex gloves, lacquer resins, varnish, soap antioxidants, insecticides, printing ink, paints, motor oil additives, disinfectants])
  2. Halo nevus
  3. Idiopathic guttate hypomelanosis
  4. Leprosy
  5. Leukoderma associated with melanoma
  6. Pityriasis alba
  7. Postinflammatory hypopigmentation
  8. Tinea versicolor
  9. Vogt-Koyanagi syndrome (i.e., vitiligo, uveitis, and deafness)
  10. Melasma
  11. Mycosis fungoides
- Congenital hypopigmentation disorders:
  1. Albinism, partial (piebaldism)
  2. Albinism, total
  3. Nevus anemicus
  4. Nevus depigmentosus
  5. Tuberous sclerosis
  6. Ito hypomelanosis

WORKUP

- Inquire about a personal and family history of autoimmune disease.
- A Wood's light examination may enhance the lesions of light-skinned individuals.

Rx TREATMENT

Treatment is indicated primarily for cosmetic purposes when depigmentation causes emotional or social distress. Depigmentation is more noticeable among patients with darker complexions. Combination therapies are associated with more improved repigmentation than monotherapies.

- Cosmetic masking agents (e.g., Dermablend, Covermark) or stains (e.g., Dy-O-Derm, Vitadye)
- Sunless tanning lotions (e.g., dihydroxyacetone)
- Repigmentation (This is achieved by the activation and migration of melanocytes from hair follicles; therefore, skin with little or no hair responds poorly to treatment.)
- Narrow-band ultraviolet B radiation (This is the preferred treatment for nonsegmental vitiligo. It is given twice weekly [not on successive days] during sessions that last from 5 to 10 min. The best results are achieved on the face, trunk, and limbs.)
- Psoralens and sunlight (e.g., PUVAsol)
- Topical mid-potency steroids (e.g., triamcinolone 0.1% or desonide 0.05% cream qd for 3 to 4 mo)
- Topical calcineurin inhibitors for face and neck lesions
- Intralesional steroid injection
- Systemic steroids (e.g., betamethasone 5 mg qd on two consecutive days per wk for 2 to 4 mo)
- Total depigmentation in cases of extensive vitiligo with 20% monobenzyl ether or hydroquinone (This is a permanent procedure, and patients will require lifelong protection from sun exposure.)
- Topical immunomodulators (e.g., tacrolimus, pimecrolimus) (These substances can also induce the repigmentation of vitiliginous skin lesions. However, their potential for systemic immunosuppression or for increasing the risk of skin cancer or other malignancies remains to be defined.)
- Calcipotriol, which is a synthetic analog of vitamin D_3 (This has also been used in combination with ultraviolet light or clobetasol, with limited results.)
- Surgical techniques can be applied to limited lesions

Von Hippel-Lindau Disease

BASIC INFORMATION

DEFINITION

Von Hippel-Lindau disease (VHL) is a rare, autosomal-dominant, inherited disorder that is characterized by the formation of hemangioblastomas, cysts, and malignancies that involve multiple organ systems.

SYNONYMS

Hippel-Lindau syndrome
Cerebelloretinal hemangioblastomatosis
Retinocerebellar angiomatosis
VHL

ICD-10CM CODE
Q85.8 Other phakomatoses, not elsewhere classified

EPIDEMIOLOGY & DEMOGRAPHICS

- The incidence of VHL is 1 case/36,000 live births.
- The mean age at the onset of clinical manifestations is 26 yr with median life expectancy of 49 yr, but the disease can present from infancy until the seventh decade of life.
- In the U.S., approximately 6000 to 7000 people have VHL.
- Affected individuals are at risk for the development of renal cell carcinoma (RCC), pheochromocytoma, pancreatic islet cell tumor, endolymphatic sac tumor, and hemangioblastomas of the cerebellum and the retina.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- There are two clinical types of VHL:
  1. Type 1 has decreased incidence of pheochromocytoma:
     a. Type 1A: Decreased risk of developing pheochromocytoma
     b. Type 1B: Decreased risk of developing both pheochromocytoma and renal cell carcinoma
  2. Type 2 has pheochromocytoma:
     a. Type 2A: Hemangioblastoma in the CNS with no RCC
     b. Type 2B: RCC and other tumors
     c. Type 2C: Only pheochromocytoma; associated with Chuvash polycythemia
- Retinal angiomas (60% prevalence):
  1. Usually occurs by age 25 yr with both VHL type 1 and VHL type 2
  2. Often multifocal and bilateral
  3. Detached retina
  4. Glaucoma
  5. Blindness
- CNS hemangioblastomas (70% prevalence):
  1. Cerebellum and spinal cord are the most common sites followed by the medulla
  2. Usually multiple; mean age at diagnosis is 25 yr; found with VHL types 1, 2A, and 2B
  3. Headache, ataxia, slurred speech, nystagmus, vertigo, nausea, and vomiting
- Renal cysts (50% to 70% prevalence) and clear cell RCC (~30% prevalence increasing to 70% at age 60):
  1. Usually occur by the age of 40 yr
  2. May be asymptomatic or cause abdominal and flank pain
  3. RCC is bilateral in 75% of patients
- Pancreatic cysts (~70% prevalence):
  1. Usually asymptomatic
  2. Large cysts can cause biliary obstructive symptoms
  3. Diarrhea and diabetes may develop if enough of the pancreas is replaced by cysts
- Pheochromocytoma (7% to 18% prevalence):
  1. Found with VHL types 2A, 2B, and 2C
  2. Bilateral in 50% to 80% of cases
  3. Hypertension, palpitations, sweating, and headache
  4. Commonly occurs with pancreatic islet cell tumors
- Papillary cystadenoma of the epididymis (25% to 60% of men with VHL):
  1. Palpable scrotal mass
  2. May be unilateral or bilateral
- Papillary cystadenoma of the broad ligaments (unknown prevalence):
  1. Usually asymptomatic
  2. Reported symptoms include pain, dyspareunia, and menorrhagia
- Endolymphatic sac tumors of the middle ear (10% to 15% prevalence):
  1. Vertigo
  2. Hearing loss
  3. Facial paralysis

ETIOLOGY

VHL is primarily caused by a mutation of the von Hippel-Lindau gene, which is located on the short arm of chromosome 3. Molecularly, the "two-hit" model of genetic dysfunction is thought to apply to VHL. Patients with one inactive VHL gene secondary to a VHL germlline mutation will develop disease following loss of the expression of the second allele through promoter hypermethylation. The VHL gene codes for a cytoplasmic protein that functions in tumor suppression.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Table E1 compares genetic diseases associated with the development of pancreatic or gut endocrine tumors.

DIAGNOSIS

- A clinical diagnosis is established in the presence of a positive family history plus a single CNS hemangioblastoma or a visceral lesion (e.g., RCC, pheochromocytoma, pancreatic cysts or tumors).
- If no clear family history is present, two or more hemangioblastomas or one hemangioblastoma with a visceral lesion is required to make the diagnosis.
- Genetic screening is up to 100% sensitive and specific, although in the 20% of patients with de novo VHL mutations, the test may be falsely negative as a result of somatic mosaicism.
- Screening family members is essential for the early detection of VHL disease.

WORKUP

Screening laboratory values and ophthalmoscopic, genetic, and imaging studies to look for sites of involvement

LABORATORY TESTS

- Complete blood count may reveal erythrocytosis that requires periodic phlebotomies.
- Electrolytes and renal function tests.
- Urine for norepinephrine, epinephrine, and vanillylmandelic acid to look for pheochromocytoma.
- Genetic studies: Complete sequencing of coding region, Southern blot, and fluorescent in situ hybridization.

IMAGING STUDIES

- Indirect and direct ophthalmoscopy, fluorescein angiography, and tonometry are used to screen for retinal angiomas and glaucoma.
- CT and MRI scanning of the abdomen is used for the screening, detection, and monitoring of patients with renal cysts or tumors, pheochromocytomas, and pancreatic cysts or tumors:
  1. Renal cysts grow an average of 0.5 cm/yr.
  2. Renal tumors grow an average of 1.5 cm/yr.
  3. Computed tomography scans are performed every 6 mo for the first 2 yr and every yr for life in patients who have had surgery for RCC.
- MRI with gadolinium (Fig. E1) is used for the screening and evaluation of CNS and spinal cord hemangioblastomas, endolymphatic sac tumors, and pheochromocytomas.
- Angiography may be performed before CNS surgery.

TABLE E1 Genetic Diseases Associated with the Development of Pancreatic or Gut Endocrine Tumors

Gene	Disease	Phenotype
Menin	Multiple endocrine neoplasia type 1	Parathyroid, pituitary, and pancreatic endocrine tumors
VHL	von Hippel-Lindau disease	Pancreatic endocrine tumors, hemangiomas, and multiple neoplasms
NF-1	Neurofibromatosis	Neurofibromas and pheochromocytomas
TSC1/2	Tuberous sclerosis	Pancreatic endocrine tumors and hamartomas

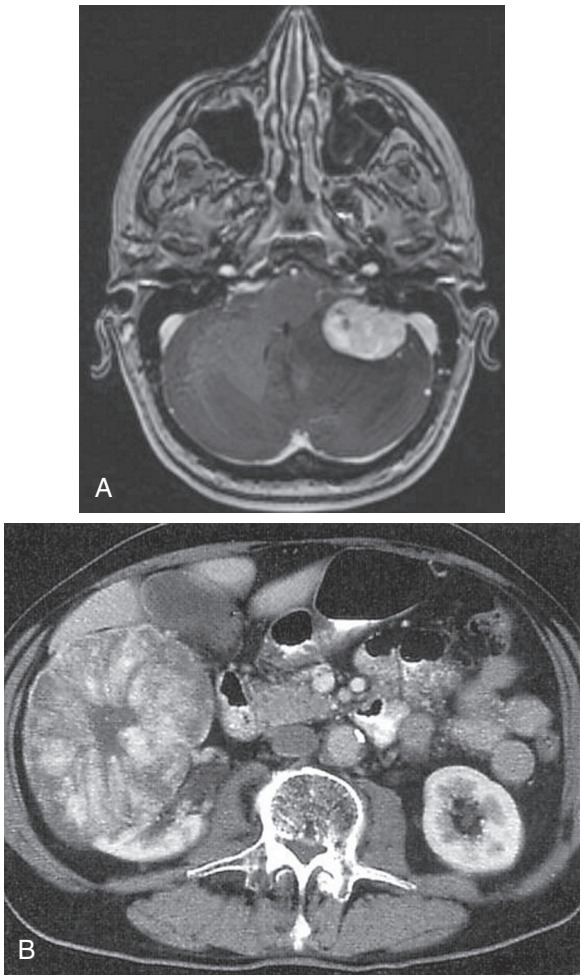

FIG. E1 Tumors in von Hippel-Lindau syndrome. A, Axial magnetic resonance image shows a cerebellar hemangioma. **B,** Axial computed tomography of the abdomen shows a renal carcinoma. (From Forbes CD, Jackson WF: *Atlas and text of clinical medicine,* 2003, Mosby.)

TREATMENT

NONPHARMACOLOGIC THERAPY

Genetic counseling

- VHL disease is inherited in an autosomal dominant fashion; thus, those with VHL have a 50% chance of passing the mutation on to their children.
- Patients with the somatic mosaicism form of VHL have varying risk of passing the condition to offspring, depending on whether or not the patient's germ cells carry the mutation. Therefore, risk may be as high as 50%.
- Patients should therefore be referred to a genetic counselor in conjunction with genetic testing.

ACUTE GENERAL Rx

- Laser photocoagulation and cryotherapy are used for patients with retinal angiomas to prevent blindness (Table E2).
- For cerebellar hemangioblastomas, treatment is surgical. External-beam radiation and stereotactic radiosurgery can also be performed.
- For renal tumors, surgery is delayed until one of the renal tumors reaches 3 cm in diameter. Nephron-sparing surgery is the preferred approach.
- Pancreatic islet cell tumors usually require surgical removal.
- Adrenalectomy is performed for pheochromocytoma.
- Antiangiogenic therapy has been shown to improve the survival of patients with RCC, with studies ongoing to assess combination therapy.

CHRONIC Rx

- Dialysis has been delayed for many patients with the use of nephron-sparing surgery.
- Renal transplantation is usually delayed for 1 yr after bilateral nephrectomy for renal tumors to ensure that no metastases have occurred.

REFERRAL

Geneticist, neurosurgeon, urologist, nephrologist, ophthalmologist, otolaryngologist, neurologist, endocrinologist, and radiation oncologist referrals should be considered

PEARLS & CONSIDERATIONS

- The most common cause of death in patients with VHL is RCC.
- More information for patients can be obtained from the von Hippel-Lindau Family Alliance (http://vhl.org).

AUTHORS: **River Cook, MD,** and **Alan Taylor, MD**

TABLE E2 Management of Different Manifestations of von Hippel-Lindau Disease

Tumor	Treatment	Screening
Retinal angiomas	Observation can be considered if angiomas are asymptomatic. If small, laser photocoagulation/ cryotherapy. in severe cases, the removal of the affected eye	Retinal examinations starting at 1 yr, repeating annually.
Central nervous system hemangioblastomas	Surgical resection for symptomatic patients or large tumors; gamma knife if difficult to remove from primary site	MRI brain and spinal cord for patients starting at 8 yr, repeating every 2-3 yr.
Renal cysts/carcinomas	For tumors <3 cm in diameter, observation; for one tumor >3 cm in diameter, remove all tumors by enucleation or partial nephrectomy; percutaneous radiofrequency ablation and cryosurgery are also performed; surgical resection is not recommended for any cyst without a tumor inside of it; nephrectomy is indicated for patients with end-stage renal disease who require dialysis because of the malignancy potential	MRI scan and quality ultrasound starting at 8 yr, repeating every yr.
Pancreatic cysts	Partial resection of the pancreas, depending on the site of the cyst	
Pheochromocytomas	Preferable to remove only the tumor itself and thus to conserve adrenal function	MRI scan and quality ultrasound starting at 8 yr, repeating every yr. Biochemical screening starting at 2 yr, repeating every yr. Bleed pressure at all visits starting at 2 yr old
Endolymphatic sac tumors	Early radical resection can preserve auditory function in majority of cases	Full audiological examination starting at 5 yr, repeated every 2-3 yr and MRI brain and spinal cord for patients starting at 8 yr, repeating every 2-3 yr. In patients with repeat ear infections, hearing loss, tinnitus, or vertigo, MRI with contrast utilizing thin slices is indicated.

CT, Computed tomography; *MRI,* magnetic resonance imaging.

BASIC INFORMATION

DEFINITION

von Willebrand disease is an inherited disorder of hemostasis characterized by a quantitative or qualitative deficiency in von Willebrand factor (vWF), a protein product of a gene located on the short arm of chromosome 12. The vWF factor is mostly synthesized in endothelial cells. von Willebrand disease results from a failure to synthesize or secrete vWF or an accelerated clearance of vWF. vWF is the carrier protein for clotting factor VIII (FVIII:C). vWF binds to denuded subendothelial collagen or glycosaminoglycans and causes platelets to adhere by acting as a ligand for glycoprotein IB on the platelet surface. This latter activity is measured in the laboratory by a test called the ristocetin cofactor (RCF). vWF circulates in plasma as a multimeric protein consisting of protomers attached by disulfide bonds. By definition, vWD is present if the level RCF is <30% of normal. A clinical entity known as low vWF exists when the level is between 30% and 60%. Such patients may exhibit a bleeding phenotype. Previously, this was considered mild vWD. There are several subtypes of von Willebrand disease. The most common type (80% of cases) is type I, where levels of vWF, FVIII:C, and RCF are reduced but concordant. Within type 1, there is type 1 mild, which is common; type 1 severe (T1S), which is rare; and type 1 C, in which the low vWF is due to accelerated clearance. There are four type 2 subtypes: type 2A, type 2B, type 2N, and type 2M. All the type 2 variants are due to a qualitative defect in vWF and show a discordancy between levels of RCF and FVIII:C. The type 2 vWD variants are characterized by low levels of RCF. Type 3 is rare and either an autosomal recessive disorder or double heterozygote and characterized by a near-complete quantitative deficiency of vWF and very low FVIII:C. Acquired vWD disease is a rare disorder that presents with mucocutaneous bleeding abnormalities and no clinical family history. It is seen often in association with hematoproliferative or autoimmune disorder or may occur in hypothyroidism. Successful treatment of the associated illness can reverse the clinical and laboratory manifestations.

SYNONYMS

Pseudohemophilia
vWD

ICD-10CM CODE
D68.0 von Willebrand disease

EPIDEMIOLOGY & DEMOGRAPHICS

- Autosomal-dominant disorder predominantly; rarely recessive or double-heterozygotic.
- Most common inherited bleeding disorder.
- Prevalence is 0.6% to 1.3% in general population, according to screening studies; estimates based on referral for symptoms of bleeding suggest a prevalence of 1 case per 10,000 persons.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Generally normal physical examination
- Mucosal bleeding (gingival bleeding, epistaxis) and gastrointestinal bleeding may occur
- Easy bruising
- Bleeding after surgery or dental extraction, menorrhagia
- Rarely, muscle or joint bleeding in type 3

ETIOLOGY

Quantitative or qualitative deficiency of vWF (see "Definition")

DIAGNOSIS

The diagnosis of von Willebrand disease generally requires two criteria: (1) a personal history, family history, or physical evidence of mucocutaneous bleeding and (2) a qualitative or quantitative decrease in functional activity of von Willebrand disease. The American Society of Hematology states that a definitive diagnosis of vWD may be made if RCF levels are <30 IU/dl.

DIFFERENTIAL DIAGNOSIS

Platelet function disorders, clotting factor deficiencies

WORKUP (FIG. 1)

3	Absent	Absent	NA	<10	Absent	

Ag, Antigen; *FVIII:C,* FVIII level; *NA,* not applicable; *RCo,* ristocetin cofactor; *RIPA,* ristocetin-induced platelet aggregation; *vWD,* von Willebrand disease; *vWF:FVIIIB,* FVIII-binding assay.
[a]Relative to the reference range (approximate values); vWF:RCo (50-200 IU/dl); vWF:Ag (50-200 IU/dl); FVIII:C (50-150 IU/dl).
[b]HMWM, High-molecular-weight multimers.
[c]Increased agglutination at low concentrations of ristocetin.
[d]The ability of vWF to bind and protect FVIII is reduced. vWF and FVIII levels can look exactly like those in males with mild hemophilia A or in symptomatic hemophilia A carrier females.
From Hoffman R: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 2 Desmopressin Responsiveness in the Various Subtypes of von Willebrand Disease

vWD Type	vWF:RCo	vWF:Ag	RCo/Ag	FVIII:C IU/dl	vWF:CB	vWF:CB/vWF:Ag
1	Increase	Increase	Remains >0.7	Increase	Increase	Remains >0.7
2A	No/little change	Increase	Remains <0.7	Increase	No/little change	Remains <0.7
2M (GP1B-binding dysfunction)	No/little change	Increase	Remains <0.7	Increase	Increase	Remains >0.7
3	No/little change	No/little change		No/little change	No/little change	

Ag, Antigen; *FVIII:C,* factor VIII level; *GP1B,* glycoprotein 1B; *RCo,* ristocetin cofactor; *vWD,* von Willebrand disease; *vWF,* von Willebrand factor; *CB,* collagen assays-binding.
Modified from Favaloro EJ: Rethinking the diagnosis of von Willebrand disease, *Thromb Res* 127;Suppl 2:17, 2011; In Hoffman R: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

- Initial testing includes prothrombin time (normal), partial thromboplastin time (normal or slightly increased), platelet count (normal), and PFA-100 (abnormal or may show high normal values in type 1 vWD).

SPECIFIC LABORATORY TESTS:

- Factor VIII coagulant activity (FVIII:C, typically decreased, may be normal in some Type 2 variants).
- vWF antigen, ristocetin cofactor (RCF), and collagen binding assay (these typically are decreased and may be concordant as in type 1 and type 3, or discordant as in type 2 variants).
- Normal platelet number and morphology.
- Prolonged bleeding time, or more commonly, prolonged PFA-100 closure times.
- von Willebrand propeptide. This measures the N-terminal propeptide of vWF. This vWFpp is secreted in equimolar amounts to the mature vWF. The ratio of vWFpp to vWF can assist in identifying vWD due to rapid clearance, as in type 1C.
- Multimeric analysis: Type 2A von Willebrand disease can be distinguished from type I by absence of medium- and high-molecular-weight multimers.
- Type 2B von Willebrand disease is distinguished from type I by the absence of high-molecular-weight multimers.
- Type 2N is a defect in the factor VIII:C binding and has normal vWF levels but very low factor VIII:C with normal multimer pattern
- Type 2M is a defect in binding to platelets (low RCF, low CBA) but normal multimers.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of aspirin and other nonsteroidal antiinflammatory drugs
- Use of antifibrinolytics such as tranexamic acid, especially for menorrhagia or oral bleeding

GENERAL Rx

- Treatment of von Willebrand disease is based on normalizing factor VIII levels and von Willebrand factor at the time of spontaneous bleeding or before an intervention.
- Use of DDAVP (Table 2): DDAVP binds to V2 receptors in certain endothelial cells and causes the release of vWF. This is suitable for the management of the milder forms of vWD. Dose is 0.3 mcg/kg in 50 to 100 ml of normal saline solution IV infused over 20 min. DDAVP is also available as a nasal spray (dose of 150 mcg spray administered to each nostril) as a preparation for minor surgery and management of minor bleeding episodes.
- When a patient undergoes surgery or receives repeated therapeutic doses of concentrates, use of a plasma-derived vWF concentrate such as Humate-P or a new recombinant vWF (Vonvendi) may need to be administered.

BASIC INFORMATION

DEFINITION

Vulvar cancer is an abnormal cell proliferation arising on the vulva and exhibiting malignant potential. The majority of vulvar cancers are of squamous cell origin (Table E1); however, other types include adenocarcinoma, basal cell carcinoma, sarcoma, and melanoma (Table E2).

SYNONYMS

Squamous cell carcinoma of the vulva (90%)
Basal cell carcinoma of the vulva
Adenocarcinoma of the vulva
Melanoma of the vulva
Bartholin gland carcinoma
Verrucous carcinoma of the vulva
Vulvar sarcoma

ICD-10CM CODE

C51.9 Malignant neoplasm of vulva, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: In 2019, it is estimated that there will be approximately 6070 new cases of vulvar cancer and that approximately 1280 women will die of the disease.

PREVALENCE: Vulvar cancer is uncommon. It comprises 3% to 5% of malignancies of the female genital tract and approximately 1% of all carcinomas found in women.

MEAN AGE AT DIAGNOSIS: Predominantly a disease of menopause, the mean age at diagnosis is 65 yr. However, the incidence shows a bimodal distribution, with both young and old women being affected.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Vulvar pruritus or pain is present (Table E3).
- May produce a malodorous discharge or present as bleeding.
- Raised lesion that may have fleshy (Fig. E1), ulcerated, leukoplakic (Fig. E2), or warty appearance; may have multifocal lesions.
- Lesions are usually located on labia majora but may be seen on labia minora, clitoris, and perineum.
- The lymph nodes of groin may be palpable.

ETIOLOGY

- There are two proposed independent pathways for the development of vulvar squamous cell carcinoma: Mucosal human papillomavirus (HPV) infection and chronic inflammatory (vulvar dystrophy) or autoimmune processes.
- Vulvar intraepithelial neoplasia has been reported in 20% to 30% of invasive squamous cell carcinoma of the vulva, but the malignant potential is unknown.
- Approximately 50% of vulvar cancers are thought to be attributable to HPV infection. HPV is more likely to be found in younger women with vulvar cancer; older women are less likely to have HPV-associated cancer.
- Other risk factors include a history of condyloma acuminatum, smoking, vulvar dystrophy, lichen sclerosis, chronic immunosuppression, hypertension, and diabetes.
- Vulvar cancer in younger women is more directly dependent on HPV infection, vulvar dysplasia, and tobacco use.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lymphogranuloma inguinale
- Tuberculosis
- Vulvar dystrophies
- Vulvar atrophy
- Paget disease

WORKUP

- Diagnosis is made histologically by biopsy
- Thorough examination of the lesion and assessment of spread. Table E4 describes FIGO staging of vulvar cancer
- Possible colposcopy of adjacent areas
- Cytologic smear of vagina and cervix
- Cystoscopy and proctosigmoidoscopy may be necessary

IMAGING STUDIES

- Chest radiography
- CT scan and MRI for assessing local tumor spread

TABLE E1 Vulvar Intraepithelial Neoplasia Histologic Subtypes and Associations

	Usual (Warty-Basaloid, Undifferentiated)	Differentiated (Simplex)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Treatment is individualized depending on the stage of the tumor. Figs. E3 through E5 describe treatment algorithm for management of patients with vulvar cancer.
- Stage I tumors with <1 mm stromal invasion are treated with complete local excision without groin node dissection. Imiquimod 5% cream, a topical immune response modulator, is also effective in the treatment of vulvar intraepithelial neoplasia.
- Stage I tumors with >1 mm stromal invasion are treated with complete local excision with groin node dissection.
- Stage II tumors require radical vulvectomy with bilateral groin node dissection.
- Advanced-stage disease may require the addition of radiation and chemotherapy to the surgical regimen.

DISPOSITION

Five-yr survival ranges from 98% for stage I to 15% for stage IV.

REFERRAL

Vulvar cancer should be managed by a gynecologic oncologist and radiation oncologist.

Vulvar Cancer (Patient Information)

AUTHOR: **Anthony Sciscione, DO**

TABLE E4 Federation of International Gynecologists and Obstetricians Staging of Invasive Cancer of the Vulva

Stage	Description
I	Tumor confined to the vulva
I_A	Lesions ≤2 cm in size confined to the vulva or perineum and with stromal invasion ≤1.0 mm*; no nodal metastasis
I_B	Lesions >2 cm in size confined to the vulva or perineum with stromal invasion greater than 1.0 mm*; no nodal metastasis
II	Tumor of any size with extension to adjacent perineal structures (one third lower urethra, one third lower vagina, anus); no nodal metastasis
III	Tumor of any size with or without extension to adjacent perineal structures (one third lower urethra, one third lower vagina, anus) with positive inguinofemoral lymph nodes
III_A	(i) With 1 lymph node metastasis (≥5 mm), or
	(ii) With 1-2 lymph node metastasis(es) (<5 mm)
III_B	(i) With ≥2 lymph node metastases (≥5 mm), or
	(ii) With ≥3 lymph node metastases (<5 mm)
III_C	With positive nodes with extracapsular spread
IV	Tumor invades other regional (two thirds upper urethra, two thirds upper vagina) or distant structures
IV_A	Tumor invades any of the following:
	(i) Upper urethra or vaginal mucosa, bladder mucosa, rectal mucosa, fixed to pelvic bone, or
	(ii) Fixed or ulcerated inguinofemoral lymph nodes
IV_B	Any distant metastasis, including pelvic lymph nodes

*The depth of invasion is defined as the measurement of the tumor from the epithelial-stromal junction of the adjacent most superficial dermal papilla to the deepest point of invasion.
From Disaia PJ et al: *Clinical gynecologic oncology,* ed 9, Philadelphia, 2017, Elsevier.

BASIC INFORMATION

DEFINITION

Waldenström macroglobulinemia (WM) is an indolent B-cell lymphoplasmacytic lymphoma (LPL) characterized by lymphoplasmacytic infiltration in the bone marrow (BM) and other organs, and a monoclonal immunoglobulin M (IgM) paraprotein in the serum. Less than 5% of LPL secrete IgG, IgA, or light chains. Rare nonsecretory cases exist.

SYNONYMS

WM
Monoclonal macroglobulinemia
Lymphoplasmacytic lymphoma

ICD-10CM CODE
C88.0 Waldenström macroglobulinemia

EPIDEMIOLOGY & DEMOGRAPHICS

- Accounts for 2% of all hematologic cancers
- A reported 1500 new cases diagnosed every yr in the U.S.
- Overall incidence: 3.4 per million person-yr in men, 1.7 per million person-yr in women
- Median age at diagnosis: 69 yr
- More common among men than women and among whites than blacks

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- 30% to 50% of patients can be asymptomatic at presentation
- Weakness, fatigue, and pallor, usually associated with anemia (50%)
- Fever, night sweats, and weight loss (30%)
- Peripheral sensory neuropathy associated with IgM demyelinating antibodies, usually affecting the feet symmetrically (20%)
- Lymphadenopathy (15%)
- Hepatosplenomegaly (15%)
- Hyperviscosity syndrome (10%), characterized by headaches, recurrent nosebleeds, blurry vision due to retinal hemorrhages (Fig. E1); retinal vein link: sausage shaped
- Acrocyanosis, livedo reticularis, purpura, and/or peripheral ulcerations usually associated with symptomatic cryoglobulinemia (5% to 10%)
- Hemolytic anemia caused by cold agglutinin disease (5%)
- Amyloidosis causing renal dysfunction, neuropathy, and/or cardiac dysfunction (<5%)
- Meningeal signs caused by CNS involvement by WM (Bing Neel syndrome; 1%)

ETIOLOGY

- The main risk factor for development of WM is having IgM monoclonal gammopathy of unknown significance (MGUS).
- Other risk factors are older age and male sex.
- Multiple reports suggest familial clustering in about 20% of the patients, which may indicate a genetic predisposition to WM and other blood cancers.
- Approximately 20% of the patients have an Ashkenazi Jewish ancestry.
- There is an increased risk of WM in people with a personal history of autoimmune diseases.
- Radiation exposure, occupational chemicals, viral infection (hepatitis C), and chronic inflammatory stimulation have been suggested, but there is insufficient evidence to substantiate these hypotheses.

DIAGNOSIS

The diagnosis of WM is usually established by laboratory blood tests and by bone marrow (BM) biopsy. Diagnosis requires demonstration of LPL involving the BM space and the presence of an IgM monoclonal paraprotein (Table 1). *MYD88 L265P* is a commonly recurring mutation in WM seen in >90% of the patients with WM and 50% to 60% of patients with IgM MGUS and can be useful in differentiating WM from other IgM-secreting B-cell disorders such as marginal zone lymphoma, IgM multiple myeloma, and atypical forms of chronic lymphocytic. Non-*L265P MYD88* mutations rarely have been described (<5%) and should be excluded in patients who test negative for *MYD88 L265P* by PCR-based assays. Mutations in the *CXCR4* gene have been described in 40% of patients, and may impact clinical presentation and response to ibrutinib treatment.

DIFFERENTIAL DIAGNOSIS

- IgM MGUS
- IgM multiple myeloma
- Marginal zone lymphoma
- Atypical chronic lymphocytic leukemia

WORKUP

In any patient suspected of having WM, specific blood tests (CBC, serum or urine protein electrophoresis [SPEP or UPEP, respectively], serum IgM level, beta 2-microglobulin, serum viscosity) should be ordered. BM biopsy confirms the diagnosis. *MYD88* mutation testing can be helpful in supporting the diagnosis of WM.

LABORATORY TESTS

- CBC with differential:
  1. Anemia is a common finding, with a median hemoglobin value of approximately 10 g/dl. WBC count is usually normal; thrombocytopenia can occur.
  2. Peripheral smear may reveal "stacked coin" rouleaux formations and malignant lymphoid cells in some patients.
- SPEP: Homogeneous M spike (monoclonal gammopathy).
- Immunoelectrophoresis: Confirms IgM responsible for the M spike.
- Serum IgM levels are high, generally >3000 mg/dl.
- High serum beta 2-microglobulin levels are associated with poor prognosis.
- Serum viscosity. Hyperviscosity usually occurs when the serum viscosity is four times the viscosity of normal serum; classic feature although presents in only 10% of cases.
- Cryoglobulins or cold agglutinins may be present.
- BM biopsy: BM reveals infiltration by a lymphoplasmacytic cell population constituted by small lymphocytes with evidence of plasmacytoid and plasma cell

TABLE 1 Physicochemical and Immunologic Properties of the Monoclonal Immunoglobulin M Protein in Waldenström Macroglobulinemia

Properties of IgM Monoclonal Protein	Diagnostic Condition	Clinical Manifestations
Pentameric structure	Hyperviscosity	Headaches, blurred vision, epistaxis, retinal hemorrhages, leg cramps, impaired mentation, intracranial hemorrhage
Precipitation on cooling	Cryoglobulinemia (type I)	Raynaud phenomenon, acrocyanosis, ulcers, purpura, cold urticaria
Autoantibody activity to myelin-associated glycoprotein, ganglioside M_1, sulfatide moieties on peripheral nerve sheaths	Peripheral neuropathies	Sensorimotor neuropathies, painful neuropathies, ataxic gait, bilateral foot drop
Autoantibody activity to IgG	Cryoglobulinemia (type II)	Purpura, arthralgia, renal failure, sensorimotor neuropathies
Autoantibody activity to red blood cell antigens	Cold agglutinins	Hemolytic anemia, Raynaud phenomenon, acrocyanosis, livedo reticularis
Tissue deposition as amorphous aggregates	Organ dysfunction	Skin: bullous skin disease, papules, Schnitzler syndrome Gastrointestinal: diarrhea, malabsorption, bleeding Kidney: proteinuria, renal failure (light-chain component)
Tissue deposition as amyloid fibrils (light-chain component most commonly)	Organ dysfunction	Fatigue, weight loss, edema, hepatomegaly, macroglossia, organ dysfunction of involved organs (heart, kidney, liver, peripheral sensory and autonomic nerves)

IgM, Immunoglobulin M.

TABLE 2 Summary of Consensus Response Criteria for Waldenström Macroglobulinemia

Response Type	Abbreviation	Criteria
Complete response	CR	Absence of serum monoclonal IgM protein by immunofixation Normal serum IgM level Complete resolution of extramedullary disease (i.e., lymphadenopathy/splenomegaly if present at baseline) Morphologically normal bone marrow aspirate and trephine biopsy
Very good partial response	VGPR	Monoclonal IgM protein is detectable 90% reduction in serum IgM level from baseline or normalization of serum IgM level Complete resolution of extramedullary disease (i.e., lymphadenopathy/splenomegaly if present at baseline) No new signs or symptoms of active disease
Partial response	PR	Monoclonal IgM protein is detectable ≥50% but <90% reduction in serum IgM level from baseline Reduction in extramedullary disease (i.e., lymphadenopathy/splenomegaly if present at baseline) No new signs or symptoms of active disease
Minor response	MR	Monoclonal IgM protein is detectable ≥25% but <50% reduction in serum IgM level from baseline No new signs or symptoms of active disease
Stable disease	SD	Monoclonal IgM protein is detectable <25% reduction and <25% increase in serum IgM level from baseline No progression in extramedullary disease (i.e., lymphadenopathy/splenomegaly) No new signs or symptoms of active disease
Progressive disease	PD	>25% increase in serum IgM level from lowest nadir (requires confirmation) and/or progression in clinical features attributable to the disease

Owen RG et al: Response assessment in Waldenström macroglobulinemia, *Br J Haematol* 160:171, 2013. In Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

differentiation. The BM infiltration should be confirmed by immunophenotypic studies (flow cytometry and immunohistochemistry) showing the following profile: sIgM+CD19+CD20+CD22+CD79+.

IMAGING STUDIES

CT of the chest, abdomen, and pelvis may show lymphadenopathy, hepatosplenomegaly, and rarely, extralymphatic/extramedullary areas of disease.

Rx TREATMENT

- Because of the incurable nature of WM, the aim of treatment is to relieve symptoms and reduce the risk of organ damage. Initiation of therapy should not be based on the IgM levels alone because this may not correlate with either disease burden or symptomatic status. Patients with smoldering or asymptomatic WM and preserved hematologic function should be observed without therapy.
- Initiation of therapy is appropriate for patients with constitutional symptoms. Considerations for the initiation of treatment include the following: significant adenopathy or organomegaly, symptomatic hyperviscosity, moderate to severe neuropathy, amyloidosis, symptomatic cryoglobulinemia or cold agglutinin disease, hemoglobin concentration <10 g/dl, or evidence of disease transformation.
- Treatment is directed at both hyperviscosity and the lymphoproliferative disorder itself.

NONPHARMACOLOGIC THERAPY

Asymptomatic patients do not require treatment, and these patients should be monitored periodically for the onset of symptoms or changes in blood tests (e.g., worsening anemia, thrombocytopenia, rising IgM levels, and serum viscosity). Plasmapheresis should be the initial treatment in patients with symptoms of hyperviscosity or cryoglobulinemia followed immediately by more definitive therapy. Serum IgM level, percentage of bone marrow involvement, serum albumin level, and serum beta 2-microglobulin level can be used to estimate the risk of requiring therapy (awmrisk.com).

INITIAL Rx

- Treatment of the lymphoproliferative disorder includes single or combination therapy. There is no universally agreed upon standard of care:
  1. Combination regimens include alkylating agents (cyclophosphamide and bendamustine) or proteasome inhibitors (bortezomib, carfilzomib, and ixazomib) in combination with rituximab. These should be used in patients with severe constitutional symptoms, symptomatic bulky disease, hyperviscosity, or profound hematologic compromise. Response rates are 80% to 90% with any of these regimens.
  2. Rituximab, a monoclonal anti-CD20 antibody, can be used in symptomatic patients who are not candidates for combination therapy. Response rates are 40% to 50%. Rituximab can be used as maintenance therapy after rituximab-containing combination regimens.
  3. In April 2015, the FDA granted approval for the oral Bruton tyrosine kinase inhibitor ibrutinib to be used in patients with symptomatic WM. The response rate to ibrutinib is 90%, with a median time to response of 4 wk. Major responses were absent in patients who do not carry the *MYD88* mutation. The response was delayed in patients who carry any *CXCR4* mutation.
  4. In August 2018, the FDA approved the combination of ibrutinib and rituximab for the treatment of symptomatic WM patients. The combination was associated with higher response rate and longer median progression-free survival than rituximab and placebo.

Rx ON RELAPSED/REFRACTORY DISEASE

- Previously treated patients can be retried on original therapy if length of response from initial therapy was substantial. If the response from the initial therapy was short, alternative first-line agents can be used.
- Other treatment options: Fludarabine, ofatumumab, thalidomide, everolimus, and clinical trials. Autologous stem cell transplantation should be considered in heavily pretreated patients.

DISPOSITION

- The progression of WM is slow and insidious, with median survival from time of diagnosis of about 10 yr. Table 2 summarizes consensus response criteria for Waldenström macroglobulinemia.
- Younger patients tend to have more prolonged survival.
- About 10% to 20% of patients die from progression of the disease.
- Some patients develop acute myelogenous leukemia, usually secondary to exposure to chemotherapy, and some patients can develop more aggressive lymphomas.

TABLE 3 Prognostic Scoring Systems in Waldenström Macroglobulinemia

Study	Adverse Prognostic Factors	Number of Groups	Survival
Gobbi et al[1]	Hgb <9 g/dl	0-1 prognostic factors	Median: 48 mo
	Age >70 yr	2-4 prognostic factors	Median: 80 mo
	Weight loss		
	Cryoglobulinemia		
Morel et al[2]	Age ≥65 yr	0-1 prognostic factors	5-yr: 87% of patients
	Albumin <4 g/dl	2 prognostic factors	5-yr: 62%
	Number of cytopenias:	3-4 prognostic factors	5-yr: 25%
	Hgb <12 g/dl		
	Platelets $<150 \times 10^9$/L		
	WBC $<4 \times 10^9$/L		
Dhodapkar et al[3]	β_2M ≥3 g/dl	β_2M <3 mg/dl + Hgb ≥12 g/dl	5-yr: 87% of patients
	Hgb <12 g/dl	β_2M <3 mg/dl + Hgb <12 g/dl	5-yr: 63%
	IgM <4 g/dl	β_2M ≥3 mg/dl + IgM ≥4 g/dl	5-yr: 53%
		β_2M ≥3 mg/dl + IgM <4 g/dl	5-yr: 21%
Dimopoulos et al[4]	Albumin ≤3.5 g/dl	Albumin ≥3.5 g/dl + β_2M <3.5 mg/dl	Median: NR
	β_2M ≥3.5 mg/L	Albumin ≤3.5 g/dl + β_2M <3.5 or	Median: 116 mo
		β_2M 3.5-5.5 mg/dl	Median: 54 mo
		β_2M >5.5 mg/dl	
Morel et al[5]	Age >65 yr	0-1 prognostic factors (excluding age)	5 yr: 87% of patients
	Hgb <11.5 g/dl	2 prognostic factors (or age >65 yr)	5 yr: 68%
	Platelets $<100 \times 10^9$/L	3-5 prognostic factors	5 yr: 36%
	β_2M >3 mg/L		
	IgM >7 g/dl

From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

- The risk of thyroid cancer, kidney cancer, and melanoma is increased in patients with WM.
- A staging system using age, serum beta 2-microglobulin level, hemoglobin level, platelet count and serum IgM concentration before treatment provide insight into prognosis and survival. Prognostic scoring systems in Waldenström macroglobulinemia are summarized in Table 3.

REFERRAL

A hematology consultation is helpful in guiding future workup, treatment, and monitoring. Participation in clinical trials is highly encouraged in patients with WM.

PEARLS & CONSIDERATIONS

COMMENTS

WM was first described in 1944 by the Swedish physician Jan Gösta Waldenström, who also described the X-linked Bruton agammaglobulinemia.

BASIC INFORMATION

DEFINITION

Warts are benign epidermal lesions caused by human papillomavirus (HPV).

SYNONYMS

Verruca vulgaris (common warts)
Verruca plana (flat warts)
Condyloma acuminatum (venereal warts)
Verruca plantaris (plantar warts)
Mosaic warts (cluster of many warts)
HPV infection

ICD-10CM CODES
B07.9 Viral wart, unspecified
B07.8 Other viral warts
A63.0 Anogenital (venereal) warts
B07.0 Plantar wart

EPIDEMIOLOGY & DEMOGRAPHICS

- Risk factors include use of communal showers, occupational handling of meat, and immunosuppression. Common warts occur most frequently in children and young adults.
- Anogenital warts are most common in young, sexually active patients. Genital warts are the most common viral sexually transmitted disease in the U.S., with up to 79 million Americans carrying the causative virus, and 14 million persons are newly infected each yr in the U.S.
- Persistent infection with oncogenic HPV types can cause cervical cancer in women as well as other anogenital and oropharyngeal cancers in women and men. 66% of cervical cancers, 55% of vaginal cancers, 79% of anal cancers, and 62% of oropharyngeal cancers are attributable to HPV types 16 or 18.
- Common warts are longer lasting and more frequent in immunocompromised patients (e.g., lymphoma, AIDS, immunosuppressive drugs).
- Plantar warts occur most frequently at points of maximal pressure (over the heads of the metatarsal bones or on the heels).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Common warts (Fig. E1) have an initial appearance of a flesh-colored papule with a rough surface; they subsequently develop a hyperkeratotic appearance with black dots on the surface (thrombosed capillaries). They may be single or multiple and are most common on the hands.
- Warts obscure normal skin lines (important diagnostic feature). Cylindrical projections from the wart may become fused, forming a mosaic pattern.
- Flat warts (Fig. E2) generally are pink or light yellow, slightly elevated, and often found on the forehead, back of hands, mouth, and beard area. They often occur in lines corresponding to trauma (e.g., a scratch), are often misdiagnosed (particularly when present on the face), and are inappropriately treated with topical corticosteroids.
- Filiform warts have a fingerlike appearance with various projections; they are generally found near the mouth, beard, or periorbital and paranasal regions.
- Plantar warts (Fig. E3) are slightly raised and have a roughened surface; they may cause pain when walking; as they involute, small hemorrhages (caused by thrombosed capillaries) may be noted.
- Genital warts (Fig. E4) are generally pale pink with several projections and a broad base. They may coalesce in the perineal area to form masses with a cauliflower-like appearance. Intraanal warts occur predominantly in patients who have had receptive anal intercourse, in contrast with perianal warts, which may occur in men and women without a history of anal sex.
- Genital warts on the cervical epithelium can produce subclinical changes that may be noted on Pap smear or colposcopy.

ETIOLOGY

- HPV infection; >150 types of viral DNA have been identified. Transmission of warts is by direct contact. Approximately 40 different types of HPV are transmitted through sexual contact.
- Genital warts: 90% are caused by HPV types 6 or 11. HPV types 16, 18, 31, 33, and 35 are found occasionally in visible genital warts (usually as coinfections with HPV 6 or 11) and can be associated with foci of high-grade, intraepithelial neoplasia, particularly in persons who are infected with HIV infection. In addition to warts on genital areas, HPV types 6 and 11 have been associated with conjunctival, nasal, oral, and laryngeal warts.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Molluscum contagiosum
- Condyloma latum
- Acrochordon (skin tags) or seborrheic keratosis
- Epidermal nevi
- Hypertrophic actinic keratosis
- Squamous cell carcinomas
- Acquired digital fibrokeratoma
- Varicella-zoster virus in patients with AIDS
- Recurrent infantile digital fibroma
- Plantar corns (may be mistaken for plantar warts)

WORKUP

- Diagnosis is generally based on clinical findings.
- Suspect lesions should be biopsied.
- The application of 3% to 5% acetic acid, which causes skin color to turn white, has been used by some providers to detect HPV-infected genital mucosa. However, acetic acid application is not a specific test for HPV infection. Therefore, the routine use of this procedure for screening to detect mucosal changes attributed to HPV infection is not recommended.

LABORATORY TESTS

- Screening for cervical cancer with cytology, which is performed by either Pap smear or liquid-based cytology. Screening guidelines recommend starting screening at age 21. Annual cytology is recommended until at least three normal cytology results are obtained.
- Colposcopy with biopsy is recommended in patients with cervical squamous cell changes.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Importance of use of condoms to reduce transmission of genital warts should be emphasized.
- Watchful waiting is an acceptable option in the treatment of nongenital cutaneous warts because many warts will disappear without intervention over time. However, many patients often request treatment because of social stigma or discomfort.
- Plantar warts that are not painful do not need treatment.
- Factors that influence selection of treatment include wart size, wart number, anatomic site of the wart, wart morphology, patient preference, cost of treatment, convenience, adverse effects, and provider experience. Factors that might affect response to therapy include the presence of immunosuppression and compliance with therapy.

GENERAL Rx

- Common warts:
  1. Application of topical salicylic acid 17%. Soak area for 5 min in warm water and dry. Apply thin layer once or twice daily for up to 12 wk, avoiding normal skin. Bandage.
  2. Liquid nitrogen and electrocautery are also common methods of removal. Cure rates for cryotherapy are 50% to 70% after three to four treatments.
  3. Blunt dissection can be used in large lesions or resistant lesions.
  4. Duct tape occlusion is also effective for treating common warts. It is cut to cover warts and left in place for 6 days. It is removed after 6 days and the warts are soaked in water and then filed with pumice stones. New tape is applied 12 hr later. This treatment can be repeated until warts resolve.
  5. Recalcitrant warts can be treated with injection of *Candida* or mumps skin antigen into the wart every 3 to 4 wk for up to three treatments, photodynamic therapy with aminolevulinic acid, pulsed dye laser, and intralesional bleomycin.
- Filiform warts: Surgical removal is necessary.

- Flat warts: Generally more difficult to treat.
  1. Tretinoin cream applied at bedtime over the involved area for several weeks may be effective.
  2. Application of liquid nitrogen.
  3. Electrocautery.
  4. 5-Fluorouracil cream applied once or twice a day for 3 to 5 wk is also effective. Persistent hyperpigmentation may occur after Efudex use.
- Plantar warts:
  1. Salicylic acid therapy (e.g., Occlusal-HP). Soak wart in warm water for 5 min, remove loose tissue, dry. Apply to area, allow to dry, reapply. Use once or twice daily; maximum 12 wk. Use of 40% salicylic acid plasters (Mediplast) is also a safe, nonscarring treatment; it is particularly useful in treating mosaic warts covering a large area.
  2. Blunt dissection is also a fast and effective treatment modality.
  3. Laser therapy can be used for plantar warts and recurrent warts; however, it leaves open wounds that require 4 to 6 wk to fill with granulation tissue.
  4. Interlesional bleomycin is also effective but generally used when all other treatments fail.
- Genital warts:
  1. Can be effectively treated with 20% podophyllin resin in compound tincture of benzoin applied with a cotton tip applicator by the treating physician and allowed to air dry. The treatment can be repeated weekly if necessary.
  2. Podofilox (Condylox 0.5% gel) is available for application by the patient. Local adverse effects include pain, burning, and inflammation at the site.
  3. Cryosurgery with liquid nitrogen delivered with a probe or as a spray is effective for treating smaller genital warts.
  4. Carbon dioxide laser can also be used for treating primary or recurrent genital warts (cure rate >90%).
  5. Imiquimod cream, 5%, is a patient-applied immune response modifier effective in the treatment of external genital and perianal warts (complete clearing of genital warts in >70% of females and >30% of males in 4 to 16 wk). Sexual contact should be avoided while the cream is on the skin. It is applied 3 times per wk before normal sleeping hours and is left on the skin for 6 to 10 hr.
  6. Sinecatechins (Veregen), a botanical drug product, is also effective for treatment of external genital and perianal warts. Formulation is a 15% ointment applied to affected area tid for up to 16 wk.
- Application of trichloroacetic acid or bichloracetic acid 80% to 90% is also effective for external genital warts. A small amount should be applied only to warts and allowed to dry, at which time a white "frosting" develops. This treatment can be repeated weekly if necessary.

DISPOSITION

- Warts can be effectively treated with the previous modalities with complete resolution in the majority of patients; however, the recurrence rate is high.
- Cervical carcinomas and precancerous lesions in women are associated with genital papillomavirus infection.
- Squamous cell anal cancer is also associated with a history of genital warts.

REFERRAL

- Dermatology referral for warts resistant to conservative therapy
- Surgical referral in selected cases
- Sexually transmitted disease counseling for patients with anogenital warts

PEARLS & CONSIDERATIONS

COMMENTS

- Subungual and periungual warts are generally more resistant to treatment. Dermatology referral for cryosurgery is recommended in resistant cases.
- Examination of sex partners is not necessary for the management of genital warts because no data indicate that reinfection plays a role.

PREVENTION

- Two HPV vaccines (Gardasil, Gardasil-9, Cervarix) have been licensed in the U.S. Advisory Committee on Immunization Practices (ACIP) recommends routine vaccination with HPV4 or HPV2 for females aged 11 to 12 yr and HPV4 for males aged 11 to 12 yr. Vaccination is also recommended for females aged 13 to 26 yr and for males aged 13 through 21 yr who were not vaccinated previously. Males aged 22 through 26 may be vaccinated. ACIP recommends vaccination of men who have sex with men and immunocompromised persons (including those with infection) through age 26 yr if not previously vaccinated. The 9-valent HPV vaccine (Gardasil-9) is approved for use in girls and women 9 to 26 yr old and boys 9 to 15 yr old. It is indicated to prevent diseases associated with HPV infection with types 6, 11, 16, 18, 31, 33, 45, 52, and 58. It appears to be more effective than the other 2 currently available vaccines. It consists of two doses. The first dose is administered at 11 to 12 yr of age, and the second dose 6 to 12 mo later. However, if the second dose is given less than 5 mo apart, a third dose will be needed at age 9 to 14. Patients with a weak immune system and in those starting vaccination at age 15 to 26 yr will need three doses. ACIP does not recommend catch-up HPV vaccination for all adults over 26 years old. Shared decision making regarding HPV vaccination is recommended for some adults age 27 through 65 who are unvaccinated.
- Male circumcision decreases heterosexual transmission of HPV.

FIG. E4 Condylomata acuminata. Verrucous papules of the labial surfaces, with a large, vegetative lesion protruding from the vagina. This toddler had been sexually abused. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E3 Plantar warts. Verrucous papules on the plantar surfaces. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

Wernicke syndrome is an acute neuropsychiatric disorder characterized by the classic triad of ophthalmoplegia, ataxia, and disturbances of mental activity or consciousness due to a deficiency of thiamine often associated with chronic alcoholism or other causes of malnutrition.

SYNONYMS

Wernicke encephalopathy (WE)
Gayet-Wernicke encephalopathy
Cerebral beriberi
Wernicke superior hemorrhagic polioencephalitis

ICD-10CM CODES

E51.2	Wernicke encephalopathy
E51.8	Other manifestations of thiamine deficiency
F04	Amnestic disorder due to known physiological condition
F10.96	Alcohol use, unspecified with alcohol-induced persisting amnestic disorder

EPIDEMIOLOGY & DEMOGRAPHICS

- A higher prevalence of WE noted on autopsy studies (0.4% to 2.8%) compared with clinical studies (0.04% to 0.13%), and the majority of affected patients are alcoholic.
  1. WE lesions on autopsy of alcohol abusers: 12.5%
  2. WE lesions on autopsy patients with alcohol-related deaths: 29% to 59%

PREDOMINANT SEX AND AGE:

- Male:female ratio of 1.7 to 1
- Estimated mortality: 17%

GENETICS:

- Biochemical studies in fibroblasts from patients with WE show transketolase, a thiamine-dependent enzyme, to have a decreased affinity for thiamine pyrophosphate.
- Variants in the high-affinity thiamine transporter gene have also been implicated.
- Thiamine deficiency causes wet (cardiovascular) beriberi more commonly in the Asian population and dry beriberi (polyneuropathy and WE) in the European population.

RISK FACTORS:

- Alcohol abuse/misuse
- Diet:
  1. Malnutrition, unbalanced nutrition, thiamine-deficient infant formulas
  2. IV hyperalimentation without thiamine supplementation
  3. Magnesium depletion–cofactor required by enzymes: Transketolase and thiamine pyrophosphokinase
- GI disorders, including recurrent vomiting (i.e., hyperemesis gravidarum) or chronic diarrhea
- GI surgical procedures (i.e., GI resection) that cause malabsorption secondary to reduced surface area of gastric and duodenal mucosa such as bariatric surgery
- Systemic cancers:
  1. Consumption of thiamine by fast-growing neoplastic cells
  2. Most common underlying disorder causing WE in children
- Chemical compounds/drugs or chemotherapeutic treatments
- Systemic diseases:
  1. Peritoneal dialysis and hemodialysis
  2. HIV/AIDS
  3. Prolonged infectious febrile disease
  4. Hypermetabolic states
  5. Thyrotoxicosis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- WE is a clinical diagnosis with a classic triad of ophthalmoplegia, ataxia, and disturbances of mental activity or consciousness, although this full triad is only seen in 16% of all patients.
- Eye movement abnormalities include nystagmus, external rectus palsies, and reduced conjugate gaze.
- Ophthalmoscopic findings include swelling of the optic discs and retinal hemorrhages.
- Clinical suspicion must remain high in patients with risk factors listed above, especially in the setting of poor nutrition.
- Diagnosis is confirmed by improvement of neurologic signs after administration of parenteral thiamine.
- Labs and radiologic studies may aid diagnosis, but these should not delay a trial of parenteral administration of thiamine.

ETIOLOGY

- The biologically active form of vitamin B_1, thiamine pyrophosphate (TP), is a coenzyme for several important biochemical pathways involved in energy production, lipid metabolism, and production of amino acids and glucose-derived neurotransmitters.
- Body's reserve for thiamine is sufficient for 18 days.
- Malnutrition for 2 to 3 weeks or a diet disproportionately high in carbohydrates and low in thiamine intake can lead to an impaired function of enzymes requiring TP.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other acute encephalopathies (Table E1)
- Paramedian thalamic infarction
- Ventriculoencephalitis, paraneoplastic encephalitis, herpes simplex encephalitis
- Miller-Fisher syndrome
- Primary central nervous system lymphoma
- Multiple sclerosis, Behçet disease, Leigh disease
- Variant Creutzfeldt-Jakob disease

WORKUP

- WE is a clinical diagnosis based on the triad of features listed previously, though the full triad is rarely seen.
- Laboratory tests and radiologic studies as listed below may be obtained to confirm diagnosis.

LABORATORY TESTS

- Do not hold thiamine treatment for the results of blood tests or imaging when there is clinical suspicion.
- Blood thiamine concentration.
- Functional measurement of erythrocyte thiamine transketolase (ETKA) before and after administration of parenteral thiamine. A diagnosis may be confirmed if ETKA is low followed by a 25% increase after thiamine supplementation.
- High-performance liquid chromatography for assessment of thiamine, thiamine mono- and di-phosphate in human erythrocytes.
- Serum magnesium concentration (depletion of magnesium may mimic features of WE).

IMAGING STUDIES

MRI of the brain may show bilaterally symmetric increase in T2 signal at the paraventricular regions of the thalamus and mammillary bodies. Other areas of increased signal include hypothalamus, periaqueductal region, floor of the fourth ventricle, and midline cerebellum.

TREATMENT

ACUTE GENERAL Rx

- Treatment should be initiated in all patients with clinical suspicion of WE. Thiamine supplementation should precede glucose administration in all patients at risk for WE.
- Alcoholics with WE: Treat with 500 mg of thiamine hydrochloride (dissolved in 100 ml of normal saline) infused intravenously over 30 minutes three times daily for 2 to 3 days.

TABLE E1 Acute and Subacute Presentation of Nutritional Deficiency Syndromes

Syndrome	Clinical Setting
Wernicke-Korsakoff syndrome	Administration of intravenous glucose to a thiamine-deficient alcoholic patient
Wernicke-Korsakoff syndrome	Intractable vomiting due to hyperemesis gravidarum or gastroplasty
Postgastroplasty neuropathy	Intractable vomiting and severe weight loss in patients following weight reduction surgical procedures
Vitamin B_{12} myeloneuropathy	Nitrous oxide administration in cobalamin-deficient patients
Central pontine myelinolysis	Sudden change in tissue osmolarity in critically ill patients or alcoholics

From Goetz CG: *Textbook of clinical neurology,* ed 3, Philadelphia, 2007, Saunders.

- If a response is observed, continue with 250 mg of thiamine hydrochloride intravenously or intramuscularly daily until clinical improvement ceases.
- Nonalcoholics with WE: Treat with 200 mg of thiamine hydrochloride (dissolved in 100 ml of normal saline) infused intravenously over 30 minutes three times daily for 2 to 3 days.
- Parenteral magnesium must be infused concurrently with thiamine.
- Side effects of parenteral thiamine hydrochloride may include generalized pruritus, transient local irritation, or rarely, anaphylactic or anaphylactoid reactions.

CHRONIC Rx

Recommended oral dose after completed parenteral treatment for WE: Thiamine 30 to 100 mg twice daily

DISPOSITION

- If prompt treatment with thiamine is not administered during the potential reversible stages of WE, Korsakoff syndrome may develop consisting of a typical pattern of irreversible memory loss emerging after the acute global confusional state of WE resolves.
- Approximately 80% of patients who survive WE develop Korsakoff syndrome.

REFERRAL

In cases of altered mental status, ophthalmoplegia, or ataxia of gait, consider neurology consultation. Treatment should be initiated as soon as WE is suspected.

PEARLS & CONSIDERATIONS

COMMENTS

- WE should be suspected in all patients with poor nutrition.
- WE is a clinical diagnosis composed of a triad of confusion, ataxia, and ophthalmoplegia, but the full triad is rarely present.
- Thiamine infusion should be initiated upon clinical suspicion of WE.
- Thiamine infusion should precede infusion of fluids with glucose in all patients with poor nutrition or clinical suspicion of WE.

PREVENTION

- Prophylactic treatment for patients with severe alcohol withdrawal, poor nourishment, or signs of malnutrition: Thiamine 250 mg IM daily for 3 to 5 days.
- In individuals susceptible to WE, 100 mg of IV thiamine should precede any glucose infusion.
- Recommended daily dose of thiamine for an average, healthy adult: 1.4 mg or 0.5 mg per 1000 kcal of carbohydrates consumed.
- Higher daily dose of thiamine recommended for children, critically ill patients, and during pregnancy and lactation.

PATIENT & FAMILY EDUCATION

In cases of known alcohol abuse, severe illness, or after bariatric surgery, the patient and family should be counseled on the importance of proper nutrition, including vitamin supplementation.

AUTHORS: **Danyelle Evans, MD, Corey Goldsmith, MD,** and **D. Brandon Burtis, DO**

BASIC INFORMATION

DEFINITION

Arthropod-borne viruses (arboviruses) are transmitted to humans primarily through the bites of infected mosquitoes. West Nile virus (WNV) is the leading cause of domestically acquired arboviral disease in the U.S.

SYNONYMS

WNV
West Nile virus fever
West Nile virus encephalitis
Neuroinvasive West Nile virus infection
Nonneuroinvasive West Nile virus infection

ICD-10CM CODE
A92.30 West Nile virus infection, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Before 1999, WNV infection was confined to areas in the Middle East, with occasional outbreaks in Europe. The infection began being diagnosed in the Western Hemisphere in 1999. First seen in the northeast and mid-Atlantic states, WNV virus infection has spread steadily each yr to new regions of the U.S., with a general westward migration pattern. Since 2004, the incidence of WNV infection waxed and waned as it spread to the western states. Human cases of WNV infection have now been reported across all the contiguous continental U.S. (sparing only Hawaii and Alaska). From 1999 through 2016, more than 780,000 cases of WNV infection occurred in the U.S., with 21,574 cases of neuroinvasive disease and 2017 deaths attributable to WNV. The overall mortality rate from reported cases of symptomatic patients with WNV is about 4%. The virus has now become the most prevalent, reportable, arthropod-borne form of viral encephalitis in North America and is likely to remain for decades to come. In 2017, 48 states and the District of Columbia reported 1425 cases of neuroinvasive WNV disease (e.g., meningitis, encephalitis, acute flaccid paralysis) for a national incidence of 0.44 cases per 100,000 population. California, Texas, and Colorado had the highest reported numbers of cases. In 2018 WNV neuroinvasive disease incidence was 25% higher than the median incidence during 2008-2017.
- The virus is carried by a number of species of birds, as well as horses and several other animals. It is transmitted to humans through the bite of an infected mosquito. For this reason, WNV infection is seen primarily from mid-summer to mid-autumn, the period of maximum mosquito intensity (Fig. E1).
- The majority of severe cases have been reported among individuals >50 yr of age. There is no gender predilection. Certain HLA haplotypes appear to predispose to severe disease (e.g., HLA-A68 and HLA-C08).
- Person-to-person transmission is fortunately rare but has been reported to occur by blood transfusion, organ transplantation, breastfeeding, and perhaps perinatal transmission; the blood supply is now routinely tested by nucleic acid testing methods to reduce the risk of transmission-acquired WNV in the U.S.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Less than 20% of infected individuals develop symptomatic disease. The initial phase of illness is nonspecific, with abrupt onset of fever (West Nile fever) accompanied by malaise, eye pain, anorexia, headache, and, occasionally, rash and lymphadenopathy. Less commonly, myocarditis, hepatitis, or pancreatitis may occur.
- Encephalitis is the most common neurologic manifestation of WNV infection. Aseptic meningitis may also occur.
- In approximately 1 in 150 cases, especially among older patients (>70 yr), severe neurologic sequelae will occur (West Nile neuroinvasive disease [WNND]). Most common among these are ataxia, cranial nerve palsies, optic neuritis, seizures, myelitis, and polyradiculitis.

ETIOLOGY

The WNV is a member of the flavivirus group, along with the yellow fever, dengue, St. Louis, and Japanese encephalitis viruses. It has a large reservoir in nature, infecting many species of birds, as well as certain mammals, and is spread to humans primarily by the bite of an infected *Culex* mosquito or other various species of mosquito, with a peak incidence in the late summer and early fall. Neurologic disease is caused by direct invasion of the CNS.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Meningitis or encephalitis caused by more common viruses (e.g., enteroviruses, herpes simplex)
- Bacterial meningitis
- Vasculitis
- Fungal meningitis (e.g., cryptococcal infection)
- Tuberculous meningitis

LABORATORY TESTS

- Complete blood count, electrolytes (hyponatremia common).
- Spinal tap and cerebrospinal fluid (CSF) examination: Typically demonstrates lymphocytic pleocytosis with normal level of glucose and elevated level of protein.
- CSF WNV IgM antibody level: Detection in symptomatic patients is diagnostic of WNND. The antibody can be detected within 9 days of fever onset and can persist for several months. There can be rare false-positive results in people recently vaccinated against Japanese encephalitis or yellow fever viruses.

IMAGING STUDIES

MRI of the brain to exclude mass lesions and cerebral edema

TREATMENT

NONPHARMACOLOGIC THERAPY

Hospitalization, IV hydration, and ventilator support may be necessary.

ACUTE GENERAL Rx

No specific therapy has been established in clinical trials. Ribavirin and interferon alfa-2b have been shown to have in vitro activity against the virus. IV immunoglobulin (IVIG) from convalescent patient plasma is under study, but one clinical trial using high-titered IVIG already has not shown clinical significance in WNND.

CHRONIC Rx

Chronic rehabilitation therapy is usually necessary for patients with severe neurologic impairment. Mental status defects following WNND appear to be more common and severe than initially recognized.

DISPOSITION

Chronic rehabilitation as needed following recovery from acute infection. Physical and mental outcome measures seem to normalize within approximately 1 yr in patients with WNV. The presence of preexisting comorbid conditions is associated with longer recovery.

REFERRAL

- Infectious disease consultant
- Public health authorities

PEARLS & CONSIDERATIONS

COMMENTS

- Diagnosis requires a high index of suspicion because disease course may be nonspecific and may mimic other, more common disorders.
- Specific laboratory diagnostic studies are available only through public-health laboratories.
- Mosquito prevention with a DEET (N,N-diethyl-meta-toluamide) spray, picaridin spray, or oil of lemon eucalyptus (OLE) or para-menthane-diol (PMD) during peak season can prevent transmission through mosquito avoidance. OLE and PMD should not be used in children aged <3 yr.
- Equine vaccines are available, but human vaccines remain years away.

BASIC INFORMATION

DEFINITION

Whiplash refers to a hyperextension injury to the neck (Fig. E1), often the result of being struck from behind by a fast-moving vehicle.

SYNONYMS

Acceleration flexion-extension neck injury
Cervical strain
Whiplash-associated disorder (WAD)

ICD-10CM CODE
S13.4 Sprain and strain of cervical spine

EPIDEMIOLOGY & DEMOGRAPHICS

- Whiplash occurs in more than 1 million people each yr, with a worldwide incidence of 15 to 200 per 100,000 people.
- Most injuries (40%) are the result of rear-end motor vehicle accidents.
- Whiplash occurs at all ages, in both sexes, and at all socioeconomic levels.
- Whiplash is more common in women than men.
- Nearly 50% of patients with whiplash seek legal advice.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Many present with a history of being involved in a motor vehicle accident and being rear-ended by another vehicle.
- Pain does not present initially but usually develops over the ensuing days.
- Symptoms include neck stiffness, headache, shoulder and back pain, tinnitus, temporomandibular joint (TMJ) pain, and mood changes.
- The presence of weakness or numbness in the arms or legs may be indicative of a more severe injury and should be evaluated by a clinician.

ETIOLOGY

- The mechanism of injury is the result of the sudden acceleration of the body forward, forcing the neck to hyperextend backward, causing injury to ligaments, muscles, bone, and/or intervertebral disk. At the end of the accident the head is thrust forward in a flexion position, sometimes causing injury to the cervical spine.
- Motor vehicle accidents, trauma from falls, contact sports, physical abuse, and altercations are all possible causes of whiplash.
- Patients with preexisting cervical facet degeneration are at higher risk for poor recovery.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Osteoarthritis
- Cervical disk disease
- Fibromyalgia
- Myofascial neck pain
- Torticollis
- Spinal cord tumor
- TMJ syndrome
- Tension headache
- Migraine headache

WORKUP

- Any patient who presents with symptoms of whiplash and musculoskeletal or neurologic signs merits a workup to exclude cervical spine fracture or herniated disk disease.
- The neck disability index has shown to have high reproducibility for quantifying disease burden related to whiplash.

LABORATORY TESTS

Laboratory studies are not helpful.

IMAGING STUDIES

- Plain cervical spine films (anteroposterior, lateral, and odontoid views)
- Flexion/extension x-rays
- CT scan to exclude fracture
- MRI as alternative or in addition to CT in selected cases of neurologic compromise

TREATMENT

NONPHARMACOLOGIC THERAPY

- Soft cervical collar for no longer than 72 hr. Prolonged courses of cervical immobilization have been found to delay the return of normal, pain-free motion.
- Nonimmobilization rehabilitation has shown faster and more complete pain relief.
- Moist heat 15 to 20 min four to six times per day.
- Continue with usual activities.
- Neck-specific exercises (isometric strengthening followed by resisted pulleys) have been shown to decrease associated radiating pain.

ACUTE GENERAL Rx

- Analgesics:
  1. NSAIDs
  2. Acetaminophen
- Muscle relaxants (short-term use)

CHRONIC Rx

NSAIDs and Tylenol can be used on a long-term basis, as needed. Referral to a physiatrist may also aid in providing multimodal therapy, such as stretching and strengthening.

DISPOSITION

- Many patients recover from the acute whiplash injury within wks.
- Factors associated with persistent and severe whiplash injuries are described in Table E1.
- 20% to 40% may develop chronic whiplash syndrome (symptoms of headache, neck pain, and psychiatric complaints that persist for 6 mo).

TABLE E1 Factors Associated with Persistent and Severe Whiplash Injuries

Severe Whiplash Injury
- High-speed injury
- Intense and rapid onset of pain
- Severe restriction of movement at presentation
- Abnormal neurology
- Bony injuries

Persistent Whiplash Injury
- High-speed injury
- Intense and rapid onset of pain
- Severe restriction of movement at presentation
- Abnormal neurology
- Bony injuries
- Increasing age
- Upper limb paresthesias
- Cervical spondylosis

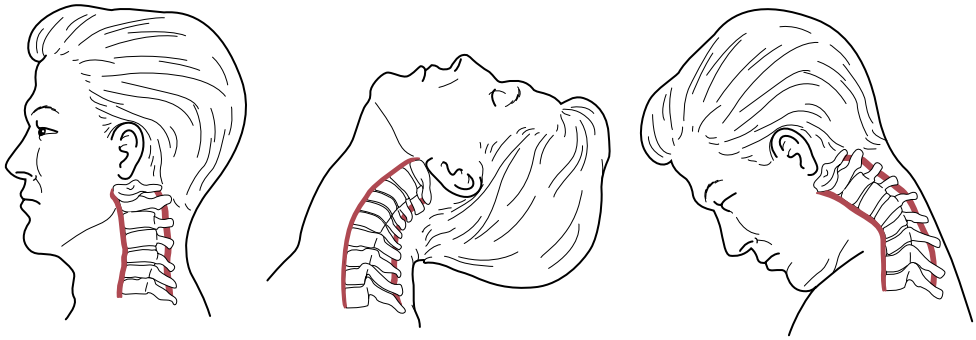

FIG. E1 Cervical flexion–extension injuries, popularly called whiplash, may tear the anterior and posterior longitudinal ligaments *(red)* and other soft tissues, herniate intervertebral disks, and exacerbate cervical spondylosis. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

- Older age, female gender, legal issues, preexisting cervical facet degeneration, and work status were found to be prognostic factors associated with a negative outcome.

REFERRAL

Orthopedic and physical therapy consultation should be sought for symptoms >6 mo.

PEARLS & CONSIDERATIONS

- Nearly one-third of all personal injury cases involve cervical injuries.
- Medical attention should be sought sooner for new weakness or numbness, changes with bowel or bladder function, or loss of dexterity.
- Recent studies have shown that patients with the quickest resolution of symptoms after an acute whiplash incident tend to have the best prognosis regarding long-term function and range of motion.

COMMENTS

The entity of chronic whiplash syndrome remains elusive. Some authorities argue that financial motivation is a factor leading to persistent neck symptoms. Other studies do not substantiate this, showing a true chronic injury to the soft tissues of the neck.

SUGGESTED READINGS

Malik AA et al: Assessment of range of movement, pain and disability following a whiplash injury, *Open Ortho J* 11:541-545, 2017.

Söderlund A et al: Exploring patients' experiences of the whiplash injury recovery process–A meta-synthesis, *J Pain Res* 11:1263, 2018.

Rydman E et al: Association between cervical degeneration and self-perceived non-recovery after whiplash injury, *Spine J*(19)30899–X, pii: S1529-9430 2019.

BASIC INFORMATION

DEFINITION

Whipple disease is a multisystem illness characterized by malabsorption and its consequences, lymphadenopathy, arthritis, cardiac involvement, ocular symptoms, and neurologic problems; it is caused by the gram-positive bacillus *Tropheryma whippelii.*

SYNONYM

Intestinal lipodystrophy (name used by Whipple in 1907)

ICD-10CM CODE
K90.81 Whipple disease

EPIDEMIOLOGY & DEMOGRAPHICS

- Uncommon illness (only about 1000 cases have been reported to date).
- Peak age: 30 to 60 yr; mean age at diagnosis, 50 yr.
- More frequent in men than women and in whites.
- Specific environmental factors have not been associated with Whipple disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

PHYSICAL FINDINGS:

- Abdominal distention, sometimes with tenderness and less commonly fullness or mass, which represents enlarged mesenteric lymph nodes
- Signs of weight loss, cachexia
- Clubbing
- Lymphadenopathy
- Inflamed joints
- Heart murmur or rub
- Sensory loss or motor weakness related to peripheral neuropathy
- Abnormal mental status examination
- Pallor

CLINICAL PRESENTATION: Whipple disease is characterized by various stages (Box E1): The prodromal stage is marked by protean symptoms and chronic arthralgias and arthritis. The steady-state stage, which follows the prodromal stage by an average time of 6 yr, is manifested by weight loss, diarrhea, or both. When the disease presents with extraintestinal symptoms (e.g., arthralgia), few clinicians will suspect the diagnosis unless or until GI symptoms are present. Weight loss, diarrhea, and arthropathies are found together in 75% of patients at time of diagnosis. The GI manifestations are those seen in malabsorption of any cause:

- Diarrhea: 5 to 10 semiformed, malodorous steatorrheic stools per day
- Abdominal bloating and cramps
- Anorexia

Extraintestinal manifestations of malabsorption:

- Weight loss, fatigue
- Anemia
- Bleeding diathesis
- Edema and ascites
- Osteomalacia

Extraintestinal involvement (Table E1):

- Arthritis (intermittent, migratory; affecting small, large, and axial joints)
- Pleuritic chest pain and cough
- Pericarditis, endocarditis
- Dementia, ophthalmoplegia, myoclonus, and many other symptoms because any portion of the CNS may be a disease site. Box E2 summarizes central nervous system symptoms and signs of classic Whipple disease
- Fever

ETIOLOGY & PATHOGENESIS

- Infectious disease caused by *T. whippeli,* an actinobacteria.
- The bacillus has never been cultured, nor has direct transmission from patient to patient ever been documented; however, the agent can be seen in tissue samples by electron microscopy and identified by polymerase chain reaction (PCR).
- Predictable response to appropriate antibiotic therapy confirms the pathogenic role of the infection.
- Tissue infiltration by macrophages is believed to be the mechanism of specific organ dysfunction and symptoms.
- Subtle defects of the cell-mediated immunity exist in active and inactive Whipple disease that may predispose certain individuals to clinical manifestations. HLA-B27 positivity is found in 26% of patients (four times higher than expected).

BOX E1 Clinical Presentations of *T. whipplei* Infection

Acute infection:
  Gastroenteritis
  Bacteremia
  Pneumonia
Asymptomatic carriage
"Classic" Whipple disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Malabsorption/maldigestion:

- Celiac disease
- *Mycobacterium avium-intracellulare* intestinal infection in patients with AIDS
- Intestinal lymphoma
- Abetalipoproteinemia
- Amyloidosis
- Systemic mastocytosis
- Radiation enteritis
- Crohn disease
- Short bowel syndrome
- Pancreatic insufficiency
- Intestinal bacterial overgrowth
- Lactose deficiency
- Postgastrectomy syndrome
- Other cause of diarrhea
- Seronegative inflammatory arthritis
- Pericarditis and pleuritis

BOX E2 Central Nervous System Symptoms and Signs of Classic Whipple Disease

Ataxia
Confusion
Convulsions
Dementia
Depression
Diplopia
Dizziness
Facial pain
Headache
Hearing loss
Hemiparesis
Hyperphagia
Hyperreflexia (± Babinski sign)
Incoordination
Lethargy, coma
Loss of vibratory and position sense
Meningoencephalitis
Mental and personality changes
Motor weakness
Muscle jerks and twitches
Muscle rigidity
Numbness
Nystagmus
Ophthalmoplegia
Papilledema
Polydipsia
Ptosis
Pupillary abnormalities
Sensory loss
Sleep disorders
Slurred speech
Stiff neck
Tinnitus
Visual difficulties (diplopia, blurring)

From Cherry JD: *Feigin and Cherry's pediatric infectious diseases,* ed 8, 2019, Elsevier.

- Lymphadenitis
- Neurologic disorders

WORKUP

Laboratory tests and imaging studies are useful; however, the diagnosis of Whipple disease is usually made by upper endoscopy and biopsy. Endoscopic findings reveal a pale yellow, shaggy mucosa alternating with an erythematous, erosive, or friable mucosa in the duodenum or jejunum.

LABORATORY TESTS

- Anemia (iron, folate, or vitamin B_{12} deficiency)
- Hypokalemia
- Hypocalcemia
- Hypomagnesemia
- Hypoalbuminemia
- Prolonged prothrombin time
- Low serum carotene
- Low cholesterol
- Leukocytosis
- Steatorrhea demonstrated by a Sudan fecal fat stain
- 72-hr stool collection demonstrating more than 7 g/24 hr of fat in the stool is impractical to perform, especially in ambulatory patients
- Defective D-xylose absorption

IMAGING STUDIES

Small bowel radiographs after barium ingestion often show thickening of mucosal folds.

BIOPSY

Infiltration of the intestinal lamina propria by PAS-positive macrophages containing gram-positive, acid-fast negative bacilli, associated with lymphatic dilation (diagnostic); PCR of the involved tissue in uncertain cases. If PAS staining of the small-bowel biopsy specimen is positive and the PCR assay is negative, the diagnosis of Whipple disease must be confirmed; this can be done by immunohistochemical testing with an antibody to *T. whippeli.* If this test result is positive, Whipple disease is confirmed.

Rx TREATMENT

- Antibiotics: TMP/SMX DS bid for 12 mo, usually preceded by parenteral administration of ceftriaxone (2 g/day) for 2 wk *or* penicillin G 2 million units q4h for 2 wk.
- Alternative regimen for sulfa-allergic patients consists of doxycycline (200 mg/day) *plus* hydroxychloroquine (200 mg tid) for 12 mo after parenteral ceftriaxone or penicillin G for 2 wk.
- Treat specific vitamin, mineral, and nutrient deficiencies.
- Patients with a neurologic recurrence of Whipple disease have a poor prognosis. Interferon gamma has been proposed for treatment of recurrent CNS disease.

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Wilson disease is an autosomal recessive disorder of copper transport with inadequate biliary copper excretion, leading to an accumulation of the metal in liver, brain, kidneys, and corneas.

SYNONYM

Progressive hepatolenticular degeneration

ICD-10CM CODE
E83.00 Disorder of copper metabolism

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: One case in 30,000
PREDOMINANT SEX: Affects men and women equally (autosomal recessive gene)
ONSET OF SYMPTOMS: Ages 3 to 40 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Most older patients present with chronic liver disease and/or neurologic manifestations, whereas younger patients may present with acute liver failure. Hepatic presentation:

- Acute hepatitis with malaise, anorexia, nausea, jaundice, elevated transaminase, prolonged prothrombin time; rarely fulminant hepatic failure
- Chronic active (or autoimmune) hepatitis with fatigue, malaise, rashes, arthralgia, elevated transaminase, elevated serum immunoglobulin G, positive antinuclear antibody and antismooth muscle antibody
- Chronic liver disease/cirrhosis with hepatosplenomegaly, ascites, low serum albumin, prolonged prothrombin time, portal hypertension

Neurologic presentation:

- Movement disorder: Tremors (Fig. E1), ataxia
- Spastic dystonia: Masklike facies, rigidity, gait disturbance, dysarthria, drooling, dysphagia
- The most common neurologic presentation in a young adult is parkinsonism

Ophthalmic:

- Kayser-Fleischer ring; indicates copper deposition in the Descemet membrane of the iris. They are most common in patients with neurologic manifestations. Typically, they are only visualized with slit-lamp examination.
- Sunflower cataracts.

Psychiatric presentation:

- Depression, obsessive-compulsive disorder, psychopathic behaviors, neuroses

Other organs:

- Hemolytic anemia due to the sudden release of copper from liver cells
- Renal disease (i.e., Fanconi syndrome with hematuria, phosphaturia, renal tubular acidosis, vitamin D–resistant rickets)
- Cardiomyopathy
- Arthritis
- Hypoparathyroidism
- Hypogonadism

PHYSICAL FINDINGS:

- Ocular: The Kayser-Fleischer ring is a gold-yellow ring seen at the periphery of the iris (Fig. E2). It is present in virtually all persons with neurologic involvement. These should be sought with slit-lamp examination by a skilled examiner
- Stigmata of acute or chronic liver disease
- Neurologic abnormalities: See previous

ETIOLOGY & PATHOGENESIS

- Dietary copper is transported from the intestine to the liver, where normally it is metabolized into ceruloplasmin. In Wilson disease, defective incorporation of copper into ceruloplasmin and a decrease of biliary copper excretion lead to accumulation of this mineral.
- The disease results from an autosomal recessive inborn error of metabolism caused by a mutation of the copper P-type adenosine triphosphatase encoded on chromosome 13q14.3 (*ATP7B* gene).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hereditary hypoceruloplasminemia.
- Menkes disease.
- Consider the diagnosis of Wilson disease in all cases of acute or chronic liver disease for which another cause has not been established.
- Consider Wilson disease in patients with movement disorders or dystonia even without symptomatic liver disease.

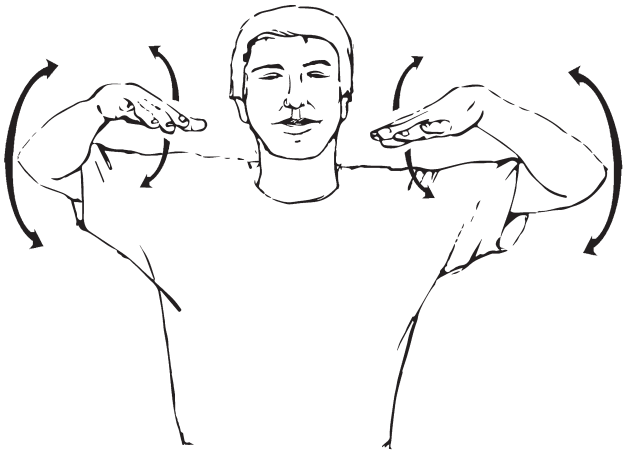

FIG. E1 Wilson disease characteristically induces parkinsonism, dystonia, dysarthria, and various tremors, including a *wing-beating tremor*. This particular tremor, which is a hallmark of the disease but only occurs in about one third of cases, consists of rhythmic, coarse, up-and-down arm movements based at the shoulders. It gives patients the appearance of flapping their arms as though they are attempting to fly. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

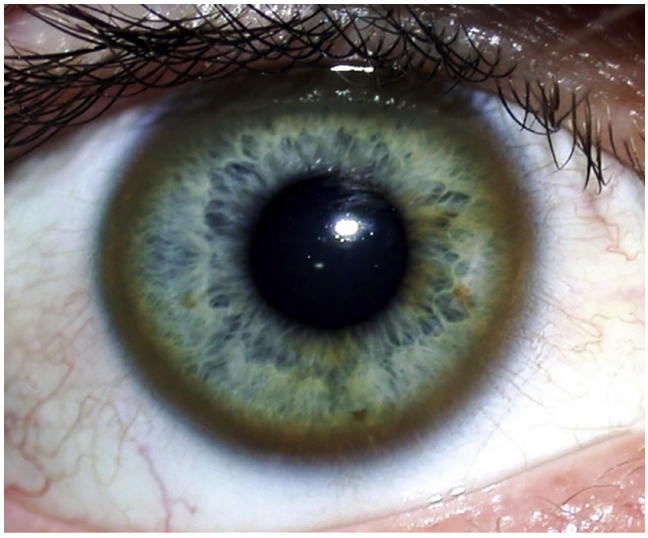

FIG. E2 Wilson disease. (Courtesy of S. Chen. From Bowling B: *Kanski's clinical ophthalmology, a systemic approach,* ed 8, Philadelphia, 2016, Elsevier.)

LABORATORY TESTS

- Table E1 compares biochemical parameters in normal adults and in patients with Wilson disease
- Low serum ceruloplasmin level (<200 mg/L) present in 95% of affected patients
- 24-hr urinary copper excretion greater than 250 mcg (normal <60 mcg); increases to greater than 1200 mcg/24 hr after 500 mg of d-penicillamine (normal <500 mcg/24 hr)
- Low serum copper
- Abnormal liver function tests (note that aspartate aminotransferase may be higher than alanine aminotransferase)
- Low serum uric acid and phosphorus
- Abnormal urinalysis (hematuria)
- Coombs-negative hemolytic anemia (due to sudden release of copper from hepatocytes)
- Molecular genetic testing for mutations of the *ATP7B* gene can also be used for diagnosis

BIOPSY

- Early:
  1. Steatosis, focal necrosis, glycogenated hepatocyte nuclei
  2. May reveal inflammation and piecemeal necrosis
- Late: Cirrhosis
- Hepatic copper content (>250 mcg/g of dry weight) (normal is 20 to 50 mcg) gold standard for diagnosis
- Histochemical confirmation of excess copper can be helpful in diagnosis, but if absent, does not exclude Wilson disease. The lack of immunoreactivity to copper-binding protein can occur because of the diffuse presence of copper in the cytoplasm and because of the assay's low sensitivity. Rhodamine and rubeanic acid stains can show dense granular lysosomal copper deposition in hepatocytes at the stage of cirrhotic nodular regeneration

Rx TREATMENT (TABLE E2)

- Trientine (triethylenetetramine): Chelator therapy; preferred agent due to fewer side effects than penicillamine
  1. 1 to 1.2 g/day divided tid
  2. Monitor CBC, iron studies
- Penicillamine (Chelator therapy):
  1. 0.75 to 1.5 g/day divided bid (with pyridoxine 25 mg/day)
  2. Monitor complete blood count (CBC) and urinalysis weekly
- Zinc: Inhibits intestinal copper absorption
  1. 50 mg tid
  2. Monitor zinc level
- Ammonium tetrathiomolybdate for neurologic symptoms
- Antioxidants
- Liver transplantation (for severe hepatic failure unresponsive to chelation); liver transplantation corrects the underlying pathophysiology and can be lifesaving

PROGNOSIS

Good with early chelation treatment

REFERRAL

To gastroenterologist, neurologist

PEARLS & CONSIDERATIONS

COMMENTS

Family screening of first-degree relatives must be undertaken. Genetic diagnosis is also useful in patients with indeterminate clinical and biochemical features.

Wilson Disease (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

TABLE E1 Biochemical Parameters in Normal Adults and in Patients with Wilson Disease

	Normal Adults	Wilson Disease*
Serum ceruloplasmin (mg/L)	200-350	0-200
Serum copper (μg/L)	700-1520	190-640
(μmol/L)	11-24	3-10
Basal 24-hr urinary copper (μg/day)	<40	40-10,000
(μmol/day)	≤0.6	>0.6
Liver copper (μg/g dry weight)	20-50	>250 (possibly >70)

*For all the assays, results in homozygotes and heterozygotes may overlap.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

TABLE E2 Recommendations for the Treatment of Wilson Disease

Drug	Dose*	Tests for Monitoring Efficacy	Tests for Monitoring Side Effects
D-penicillamine (+ pyridoxine 25 mg daily)	Initial: 1-1.5 g/day (adults) or 20 mg/kg/day (children) divided into two or three doses	24-hour urinary copper: 200-500 μg (3-8 μmol)/day as target; estimated non–ceruloplasmin-bound copper <200 μg/L	Complete blood count; urinalysis; skin examination
	Maintenance: 0.75-1 g/day as needed to maintain cupruresis	Estimated non–ceruloplasmin-bound copper <100 μg/L	
Trientine†	Initial: 1-1.2 g/day divided into two or three doses‡	Same as for D-penicillamine	Complete blood count; iron studies
	Maintenance: Same	Same as for D-penicillamine	
Zinc	Initial: 50 mg elemental zinc three times daily (adults)§	24-hour urinary copper: <75 μg (1.2 μmol)/day as target	Serum zinc level Serum AST and ALT levels
	Maintenance: Titrate the dose based on efficacy monitoring data¶	Estimated non–ceruloplasmin-bound copper <100 μ/L	

*All medications should be taken before or after mealtime if possible, but the timing of the dose may have to be adjusted to enhance consistent adherence to treatment.
†Requires refrigeration.
‡The dose of trientine in children is not established (≈20 mg/kg/day).
§The dose of zinc in children is not established. Typical dosing is 25 mg of elemental zinc three times daily until adult stature (≈50 kg body weight) is achieved, when the adult dose of 50 mg of elemental zinc three times daily is used. The dose is not well defined for children younger than 5 yr. The dose in children also can be titrated to achieve optimal 24-hr urinary copper excretion.
¶The 24-hr urinary copper excretion reflects total body copper load and thus can be used to monitor zinc treatment although zinc does not cause cupruresis; some groups prefer to use the estimated non-ceruloplasmin-bound copper determination as a guide.

Wolff-Parkinson-White Syndrome PTG

BASIC INFORMATION

DEFINITION

Wolff-Parkinson-White (WPW) syndrome is a congenital heart condition in which, in addition to the normal electrical conduction through the atrioventricular (AV) node, there is an accessory pathway (AP) that connects the atria to the ventricles. Consequently, a portion of the ventricular myocardium is depolarized via the AP earlier than the normal AV nodal conduction, resulting in ventricular preexcitation. The terms "WPW syndrome" and "WPW pattern" often are used in describing patients with ventricular preexcitation. Patients with WPW syndrome have ECG findings of preexcitation, including short PR and slurring of the initial segment of the QRS complex known as the delta wave together with symptoms suggestive of arrhythmia or documented arrhythmia, which may be atrioventricular (AV) reentrant tachycardia, atrial fibrillation (AF), or both. Patients with the WPW pattern have characteristic ECG findings of preexcitation without evidence of arrhythmia.

SYNONYMS

Preexcitation syndrome
WPW

ICD-10CM CODE
I45.6 Preexcitation syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- The prevalence of a WPW pattern on the surface ECG is 0.1% to 0.3% in the general population. The prevalence is increased to 0.55% in first-degree relatives of affected patients. It is estimated that approximately 65% of adolescents and 40% of individuals older than 30 yr with WPW pattern on a resting ECG are asymptomatic.
- The prevalence of WPW is higher among males and decreases with age.
- Most patients with WPW have structurally normal hearts, but it may also occur in patients with congenital heart disease, most notably in patients with Ebstein anomaly, which is associated with right-side AP and often multiple and slowly conducting APs.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The physical examination is usually unremarkable.
- Symptoms are typically related to tachyarrhythmias, including the following:
  1. Palpitations, lightheadedness, anxiety, dyspnea, or chest pain
  2. Syncope or near syncope
  3. Sudden cardiac death
- The common arrhythmias in WPW syndrome are:
  1. Supraventricular tachycardia: AV reciprocating tachycardia (AVRT). This is the most common arrhythmia, further classified as orthodromic AVRT (narrow complex tachycardia, with antegrade conduction through the AV node and retrograde conduction via the AP that occurs in 70% of symptomatic patients) or antidromic AVRT (wide complex tachycardia with antegrade conduction via the AP and retrogradely through the AV node, which occurs in 4% to 5% of patients).
  2. AF (~10% to 38%), the second most common tachycardia, can be complicated by a very rapid ventricular response due to conduction over the AP, which can lead to ventricular fibrillation (VF) and sudden death. This risk is dependent on the antegrade refractory period of AP during AF.
  3. The risk of sudden death in symptomatic patients with WPW syndrome is estimated to be approximately 0.25% per yr or 3% to 4% over a lifetime.
- In a meta-analysis including approximately 2000 subjects with asymptomatic WPW, children had a sudden death rate of 1.9 compared with 0.9 in adults per 1000 patient-yrs of follow-up. This incidence is comparable with the estimated 0.1% per yr risk of death in the general population in Europe, Japan, and the U.S.

ETIOLOGY & PATHOGENESIS

- APs are thought to be an embryologic remnant, as substantiated by reports of SVT in uterus and by a greater prevalence of WPW in newborns and infants.
- Left free wall APs are most common followed by posteroseptal, right free wall, and anteroseptal locations.
- Some patients with WPW syndrome (~5% to 10%) have multiple APs.
- In subjects with WPW, two parallel routes of AV conduction are present: One is subject to delay through the AV node, and the other occurs without delay through the AP and results in preexcitation of the ventricles. The resulting QRS complex is a fusion beat, as a portion of the ventricle is preexcited and activated via the AP giving rise to the delta wave, and the remainder of the ventricle is activated by the normal activation pathway (Fig. 1).

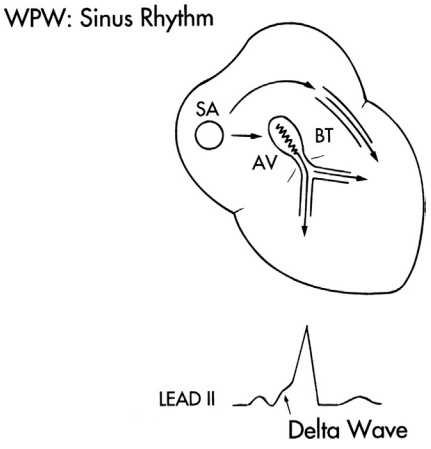

FIG. 1 With Wolff-Parkinson-White (WPW) syndrome, an abnormal accessory pathway called a bypass tract connects the atria and the ventricles. (From Goldberger AL [ed]: *Clinical electrocardiography: a simplified approach,* ed 6, St Louis, 1999, Mosby.)

- Reciprocating tachycardias occur when conduction is anterograde in one pathway (usually the AV node, i.e., orthodromic AVRT) and retrograde in the other (usually the AP) as a result of different refractory periods. This is usually initiated by a premature atrial or ventricular depolarization.

DIAGNOSIS

- Three basic features characterize the ECG abnormalities associated with WPW pattern:
  1. PR interval <120 ms.
  2. QRS complex can be >120 ms with a slurred, slowly rising onset of QRS in some leads (delta wave) and a normal terminal QRS portion. The width of the QRS complex depends on the amount of preexcitation ventricular tissue.
  3. Secondary ST-T wave changes directed in an opposite direction to the major delta and QRS vectors may be present.
- ECG patterns with abnormal QRS complexes and ST and T changes can mask or mimic myocardial infarction (in particular posteroseptal AP with negative delta waves in the inferior wall, which mimics old inferior wall myocardial infarction), bundle branch block (Fig. 2), or ventricular hypertrophy.
- Most commonly seen tachycardia (orthodromic AVRT) is characterized by a normal QRS with a regular rate of 150 to 250 bpm. Onset and termination are abrupt.
- Variants of preexcitation:
  1. Lown-Ganong-Levine syndrome is characterized by a short PR interval, a narrow QRS complex without a delta wave, and a clinical syndrome of paroxysmal SVTs. Postulated mechanisms to the short PR interval include a variant of the normal, enhanced sympathetic tone or specialized intra-nodal fibers with enhanced AV nodal conduction.
  2. Atriofascicular accessory pathway (Mahaim fiber): A slowly conducting AP with AV-nodal like properties, which connects the right atrium with the right bundle branch or the apical myocardium. In the baseline state, minimal or no preexcitation may be present. During preexcitation the QRS appears like a typical LBBB pattern.
  3. Nodoventricular or nodofascicular APs: Rare variants that connect the AV node and the ventricle or the bundle branch appropriately.
- An electrophysiology study is the gold standard to confirm the diagnosis, determine the location, and assess the conduction properties of the AP.

RISK STRATIFICATION

- Intermittent and abrupt loss of preexcitation on a beat-to-beat basis is indicative of lower risk, assessed with Holter monitoring or with an exercise stress test. The loss of preexcitation after administration of the antiarrhythmic drug procainamide has also been used to indicate a low-risk subgroup.

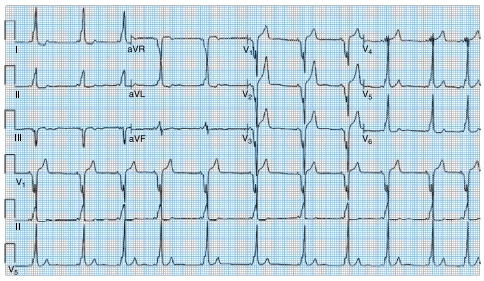

FIG. 2 Wolff-Parkinson-White (WPW) syndrome. This 12-lead electrocardiogram with rhythm strips shows preexcitation with an accessory pathway connecting the right atrium to the right ventricle. This gives rise to a pattern like left bundle branch block because the ventricles are activated over the right-sided accessory pathway. The tracing shows the typical characteristics of WPW syndrome, including a short PR interval, a wide QRS complex, and a delta wave. (From Olshansky B et al: *Arrhythmia essentials*, ed 2, Philadelphia, 2017, Elsevier.)

BOX 1 Goals of Electrophysiologic Evaluation in Patients with Wolff-Parkinson-White Syndrome

- Confirmation of the presence of an accessory pathway (AP)
- Evaluation for the presence of multiple APs
- Localization of the AP(s)
- Evaluation of the refractory period of the AP and its implications for life-threatening arrhythmias
- Induction and evaluation of tachycardias
- Demonstration of the AP role in the tachycardia
- Evaluation of other tachycardias not dependent on the presence of the AP
- Ablation of the AP, when indicated.

From Issa Z et al: *Clinical arrhythmology and electrophysiology,* ed 2, Philadelphia, 2012, WB Saunders.

- In patients with a persistent preexcitation pattern, electrophysiology study is the procedure of choice for risk stratification.

Rx TREATMENT

Goals of electrophysiologic evaluation in patients with WPW syndrome are described in Box 1.

ACUTE MANAGEMENT

- Urgent cardioversion, for an acute tachycardia episode with hemodynamic instability.
- Narrow QRS tachycardia (c/w orthodromic AVRT):
  1. Vagal maneuvers and/or IV adenosine.
  2. IV beta-blockers, diltiazem, or verapamil can be administered for regular and **narrow** QRS tachycardia, implying antegrade conduction via the AV node, when the patient is hemodynamically stable and IV adenosine is ineffective.
- Wide QRS complex tachycardias (WCTs):
  1. Most commonly caused by atrial fibrillation with antegrade conduction via the AP and the AV node. AV nodal blocking therapies (i.e., beta-blockers, calcium channel blockers, digoxin, and adenosine) are potentially dangerous and should be avoided in these cases because of the risk of causing VF by enhancement of the ventricular response through the accessory pathway when the AV node is blocked and the blood pressure is lowered.
  2. Stable patients with preexcited AF can be managed with IV procainamide. Electrical cardioversion should be performed if the patient is hemodynamically unstable.
  3. In a patient with WCT due to antidromic tachycardia, drug treatment may be directed at the AP or at the AV node because both are critical components of the tachycardia circuit.

Long-term management:

- Asymptomatic:
  1. In low-risk patients with intermittent loss of preexcitation, AP effective refractory period (APERP) ≥250 ms, or shortest preexcited RR interval (SPERRI) ≥250 ms, no therapy is required.
  2. In high-risk patients with APERP ≤250 ms or SPERRI≤ 250 ms, competitive athletes, or high-risk occupation (i.e., pilots), ablation should be considered.
- Symptomatic:
  1. Patients who presented with aborted sudden cardiac death, preexcited tachycardia (i.e., atrial fibrillation, flutter, atrial tachycardia), or syncope suggestive of cardiac origin should undergo an electrophysiology study for further characterization and ablation of the AP accordingly.
  2. Patients with symptomatic palpitations or documented AVRT should be offered an electrophysiology study and ablation of the AP to prevent recurrence and to allow the patient to avoid long-term medical therapy. Ongoing management for stable patients with history of orthodromic AVRT who are not candidates for, or prefer not to undergo, catheter ablation:
     - Class IC antiarrhythmics (flecainide, propafenone), in the absence of structural heart disease.
     - Class III antiarrhythmics (amiodarone, sotalol).
     - Oral beta blockers, diltiazem, or verapamil.

Yellow Fever

BASIC INFORMATION

DEFINITION

Yellow fever is a mosquito-borne infection, primarily of the liver, with systemic manifestations caused by the yellow fever virus (YFV), a flavivirus that infects the liver. The clinical spectrum ranges from asymptomatic infection to life-threatening disease with severity and mortality highest in the elderly.

SYNONYM

Tropical hemorrhagic fever from YFV

ICD-10CM CODE
A95.9 Yellow fever, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

GEOGRAPHIC DISTRIBUTION:

- South America and Africa, in countries between +15 and –15 degrees latitude (Fig. E1).
- The World Health Organization estimates there are more than 200,000 cases per yr with 30,000 deaths per yr. More than 90% of cases occur in Africa.
- Outbreaks of yellow fever occurred in Angola in 2016 and in Brazil: Started in the state of Minas Gerais in 2017 and then spread to other regions and continues currently.

INCIDENCE: Approximate attack rates of 3% in Africa and Amazon
PREVALENCE: Endemic areas: 20% of population
PREDOMINANT SEX: In Africa and the Amazon, male agricultural workers

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most patients with yellow fever are asymptomatic
- The onset of illness appears suddenly 3 to 6 days after the bite of an infected mosquito
- Viremic (early) phase:
  1. Fever, chills
  2. Severe headache
  3. Lumbosacral pain
  4. Myalgias, nausea, malaise
  5. Conjunctivitis
  6. Relative bradycardia (Faget sign)
- After brief recovery, toxic phase:
  1. Jaundice
  2. Oliguria
  3. Albuminuria
  4. Hemorrhage
  5. Encephalopathy
  6. Shock
  7. Acidosis
- Case-fatality rate: 25% to 50%

ETIOLOGY

- YFV *(L. flavus)*: Small enveloped single-strand RNA virus
  1. Flavivirus infects hepatic cells
  2. Late in infection, cytopathic effects (antibody- and cell-mediated) produce pathology
- Vector
  1. *Aedes aegypti* (urban)
  2. *Aedes* spp., *Haemagogus* (especially in Amazon) mosquitos (sylvan)
  3. Primary hosts: Humans and simian species
  4. Exists in two transmission cycles:
     a. Sylvatic or jungle cycle involving mosquitoes and nonhuman primates
     b. Urban cycle involving mosquitoes and humans

PATHOGENESIS & PATHOLOGY:

- Virus replication begins at site of mosquito bite, spreading to lymphatic channels and regional lymph nodes. Viremic spread to other organs, especially liver, spleen, and bone marrow.
- Shock and fatal illness result from direct damage to organs and vasoactive cytokines.
- Viral antigen found in hepatocytes, kidneys, and myocardium.
- Midzone necrosis of liver lobules primarily affected and is highly characteristic.
- Hemorrhages of mucosal surfaces of GI tract.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Viral hepatitis
- Leptospirosis
- Malaria
- Typhoid fever
  1. Typhus
  2. Relapsing fever
- Other hemorrhagic fevers such as dengue and Ebola (see Table E1)

LABORATORY TESTS

- CBC
  1. Mild leukopenia
  2. Thrombocytopenia
  3. Anemia
- LFTs
  1. AST levels exceed ALT levels
  2. Alkaline phosphatase normal or slightly elevated
  3. Elevated bilirubin levels
- Elevated BUN and creatinine
- Proteinuria
- Coagulation studies
  1. Demonstrate abnormal prothrombin time *or*
  2. Reveal DIC
- Terminal hypoglycemia
- CSF
  1. Pleocytosis
  2. Elevated protein count
- Specific diagnosis confirmed by:
  1. Viral isolation from blood: Labor-intensive and may take wks
  2. Viral antigen in serum (ELISA)
  3. Viral RNA by polymerase chain reaction (PCR) in blood or tissue
  4. IgM-capture ELISA
     a. Preferred serologic test
     b. Appears within 5 to 7 days
     c. Rising Ab confirmed by paired sera
     d. Cross-reactivity with other flavivirus infections
  5. Immunohistochemical staining of postmortem liver biopsy specimens

TREATMENT

ACUTE GENERAL Rx

- Acetaminophen (for headache and fever) and H_2 blockers (GI bleeding); avoid aspirin because of bleeding risk
- Blood transfusion, volume replacement for hemorrhage and shock
- Dialysis for renal failure
- Avoidance of sedatives and drugs dependent on hepatic metabolism

DISPOSITION

Follow up until hepatic, renal, CNS disease resolved. Infection in humans is capable of producing hemorrhagic fever and is fatal in 20% to 50% of persons with severe disease.

REFERRAL

To infectious diseases expert for accurate diagnosis and management

TABLE E1 Viral Hemorrhagic Fevers (HFs)

Mode of Transmission	Disease	Virus
Tick-borne	Crimean-Congo HF*	Congo
	Kyasanur Forest disease	Kyasanur Forest disease
	Omsk HF	Omsk
Mosquito-borne†	Dengue HF	Dengue (four types)
	Rift Valley fever	Rift Valley fever
	Yellow fever	Yellow fever
Infected animals or materials to humans	Argentine HF	Junin
	Bolivian HF	Machupo
	Lassa fever*	Lassa
	Marburg disease*	Marburg
	Ebola HF*	Ebola
	HF with renal syndrome	Hantaan

*Patients may be contagious; nosocomial infections are common.
†Chikungunya virus is associated infrequently with petechiae and epistaxis. Severe hemorrhagic manifestations have been reported in some cases.

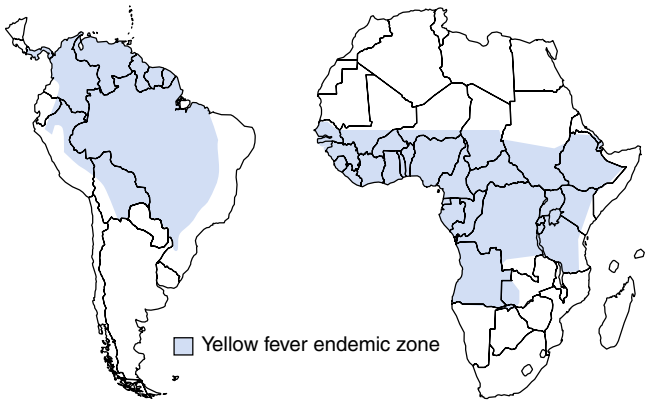

FIG. E1 Geographic distribution of yellow fever in Africa and the Americas. (From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.)

PEARLS & CONSIDERATIONS

PREVENTION

- Yellow fever is preventable by immunization.
- Recovery from yellow fever confers lasting immunity.
- Live, attenuated yellow fever vaccine (YF-Vax) provides protective immunity in 95% of vaccinated patients within 10 days of vaccination. Reimmunization had been recommended at 10-yr intervals for travelers, but in June 2015 the ACIP issued recommendations stating that a single primary dose of a yellow fever vaccine is adequate for most travelers, and in June 2016 the WHO recommended to stop requiring vaccine reimmunization, as one dose confers lifelong immunity. Vaccine certificate to verify immunization status is required before travel in many tropical countries in South America and Africa. Vaccine nonresponders are uncommon but exhibit excess antiinflammatory cytokine profiles and with high levels of T-regulatory cells; this problem is more likely to be observed in elderly individuals.
- The U.S. Advisory Committee on Immunization Practices (ACIP) still recommends reimmunization for the following:
  1. Women who were pregnant at time of first vaccine
  2. Recipients of hematopoietic stem cell transplant
  3. Individuals who were HIV positive (CD4 >200) at the time of first vaccination
  4. Individuals who plan to spend extensive time in endemic areas or travel to highly endemic areas (West Africa)
  5. Lab personnel who handle the yellow fever virus
- Vaccine contraindicated in:
  1. Infants <6 mo (postvaccinal encephalitis)
  2. Immunosuppressed patients, such as those with HIV <200 CD4 count, leukemia, and lymphoma
  3. Pregnant women and nursing mothers, as it is a live weakened virus. Vaccine can be given in pregnancy and breastfeeding if the risk of acquiring the disease from travel to areas involved with the disease is significantly higher than the vaccination risks
  4. Patients with egg hypersensitivity
- Adverse effects of vaccine:
  1. General
     a. Mild headaches, myalgias, low-grade fevers (25% vaccinees in clinical trials)
     b. Immediate hypersensitivity reaction (history of egg allergy)
  2. Vaccine-associated neurotropic disease (postvaccine encephalitis) (1.8 cases per million)
     a. Primarily among infants
     b. Adult cases only in first-time vaccine recipients
  3. Vaccine-associated viscerotropic disease (2.2 cases per million)
     a. Disease syndrome resembling wild-type yellow fever, often fatal
     b. All cases in first-time vaccinees; age >60 yr are at particular risk
- Yellow fever vaccine response can be significantly reduced by coadministration of the live virus combined vaccine with measles, mumps, and rubella.
- YF-Vax became unavailable in the U.S. in mid-2017, and the shortage is expected to last until mid-2019 when a new production facility is ready. An alternative but similar formulation, Stamaril (manufactured in Europe), is available under the FDA's Expanded Access Program at high-volume yellow-fever vaccination centers.

Zenker Diverticulum (PTG)

BASIC INFORMATION

DEFINITION

Zenker (Pharyngoesophageal) diverticulum (ZD) refers to the acquired physiologic obstruction of the esophageal introitus that results from mucosal herniation posteriorly between the cricopharyngeus muscle and the inferior pharyngeal constrictor muscle (Fig. E1).

SYNONYMS

Pharyngoesophageal diverticulum
Pulsion diverticulum
ZD

ICD-10CM CODE
K22.5 Diverticulum of esophagus, acquired

EPIDEMIOLOGY & DEMOGRAPHICS

- The most common type of diverticulum of the upper gastrointestinal tract
- Rare disease with annual incidence estimated 1/50,000 per yr
- Most commonly presents after the age of 60 yr, more commonly seen in males
- Peak incidence is seventh to ninth decades
- Associated with gastroesophageal reflux disease (GERD) and hiatal hernia

PHYSICAL FINDINGS & CLINICAL PRESENTATION

A small ZD may be asymptomatic. As it becomes larger, symptoms may include:

- Dysphagia to solids and liquids (most common)
- Regurgitation of undigested food
- Sensation of globus or fullness in the neck
- Cough
- Halitosis
- Aspiration pneumonia
- Weight loss
- Voice changes
- Sialorrhea (excessive drooling)

ETIOLOGY

- The specific cause is not known. The leading hypothesis suggests a discoordination of the swallowing muscles (specifically, incomplete relaxation of the cricopharyngeus muscle) that leads to an increased pressure on the mucosa of the hypopharynx, resulting in a progressive distention of that mucosa in its weakest area (posterior wall in "Killian triangle," the point between the oblique fibers of the inferior pharyngeal muscle and the horizontal fibers of the cricopharyngeus muscle). The end result is the formation of a false diverticulum where food elements and secretions may be lodged, causing the symptoms listed previously.
- ZD may also occur after anterior spinal surgery or cervical spine injury.

DIAGNOSIS

- Clinical presentation and barium swallow typically make the diagnosis of ZD.
- Neck ultrasound can also be used.
- Esophageal manometry can help elucidate the pathogenesis but not required for diagnosis.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis is similar to anyone presenting with dysphagia:

- Achalasia
- Esophageal spasm
- Esophageal carcinoma
- Esophageal webs
- Peptic stricture
- Lower esophageal (Schatzki) ring
- Foreign bodies
- Central nervous system disorders (stroke, Parkinson disease, amyotrophic lateral sclerosis, multiple sclerosis, myasthenia gravis, muscular dystrophies)
- Dermatomyositis
- Infection

WORKUP

Barium swallow is the test of choice. Upper endoscopy (Fig. E2) runs the risk of perforation.

LABORATORY TESTS

Not specific

IMAGING STUDIES

- Barium swallow: Demonstrates a herniated sac with a narrow diverticular neck that typically originates proximal to the cricopharyngeus at the level of C5 to C6 (Fig. E3).
- Endoscopy is only indicated if barium studies show mucosal irregularities to rule out neoplasia.
- Oropharyngeal-esophageal scintigraphy has recently been shown to be an effective, sensitive, and simple diagnostic study for both qualitative and quantitative analyses.
- Chest radiography is performed in cases of suspected aspiration pneumonia.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Soft mechanical diet can be tried in patients with symptoms of dysphagia.
- Avoid seeds, skins, and nuts.

ACUTE GENERAL Rx

- Endoscopic techniques (esophagodiverticulostomy) have largely replaced conventional surgery and include:
  1. Endoscopic stapler diverticulotomy (may be the initial treatment of choice)
  2. Microendoscopic carbon dioxide laser surgical diverticulotomy
  3. Diverticulum <3 cm is a contraindication to endosurgical approach.
  4. Peroral endoscopic myotomy (POEM) is technically successful in 97% and clinically successful (complete or near complete resolution of dysphagia) in 92%.[1]
  5. Head-to-head comparison with surgical repairs showed endoscopic techniques to be similar in results, relief of symptoms, and patient satisfaction.
- Surgical repair (Table E1) is the conventional treatment for symptomatic patients (dysphagia, cough, aspiration) with excellent relief of symptoms in nearly all patients and low procedural mortality (<1.5%). Procedures include:
  1. Cervical diverticulectomy with cricopharyngeal myotomy (most common approach)
  2. Diverticulopexy or diverticular inversion with cricopharyngeal myotomy
  3. Diverticulectomy alone
  4. Cricopharyngeal myotomy alone

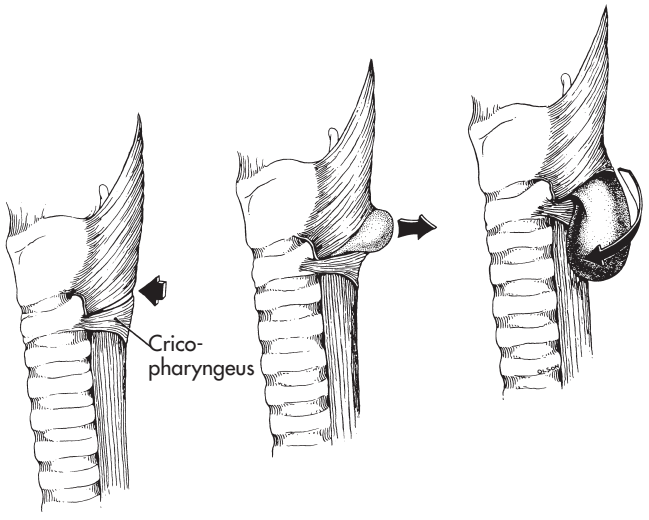

FIG. E1 Formation of pharyngoesophageal (Zenker) diverticulum. Left, Herniation of the pharyngeal mucosa and submucosa occurs at the point of transition *(arrow)* between the oblique fibers of the thyropharyngeus muscle and the more horizontal fibers of the cricopharyngeus muscle. **Center** and **right,** As the diverticulum enlarges, it dissects toward the left side and downward into the superior mediastinum in the prevertebral space. (From Sabiston D: *Textbook of surgery,* ed 15, Philadelphia, 1997, WB Saunders.)

[1] Yang J et al: An international study on the use of peroral endoscopic myotomy in the management of Zenker's diverticulum, Gastrointest Endosc 91(1):163-168, 2020.

FIG. E2 Endoscopic view of a midesophageal diverticulum. These diverticula are most apparent when the esophagus is well insufflated. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

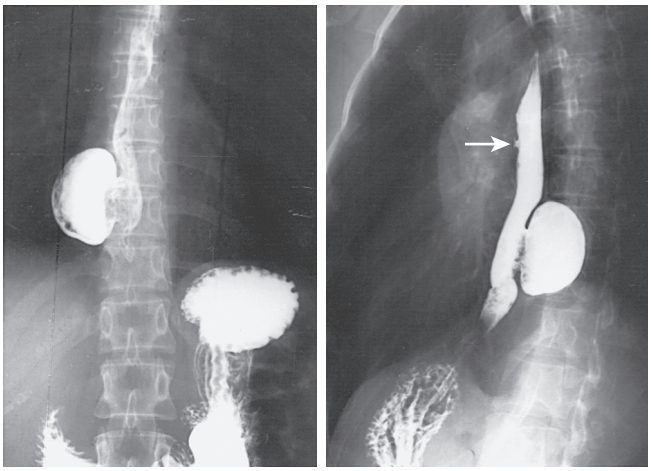

FIG. E3 Posteroanterior *(left)* and oblique *(right)* views from barium esophagogram showing both a typical diverticulum of the junction of the mid-esophagus and distal esophagus and a small traction diverticulum *(arrow)* of the mid-esophagus. (From Sabiston D: *Textbook of surgery,* ed 15, Philadelphia, 1997, WB Saunders.)

TABLE E1 Summary of Operative Techniques for Management of Zenker Diverticulum

Technique	Description
Endoscopic diverticulotomy	Transoral endoscopic division of cricopharyngeus muscle and the septum between the diverticulum and esophagus using electrocautery, laser, or stapler
Open diverticulectomy with myotomy	Excision of diverticulum with myotomy of the cricopharyngeus muscle
Open diverticulopexy with myotomy	Mobilization of the diverticulum with suture fixation above the neck of the diverticulum to the prevertebral fascia with myotomy of the cricopharyngeus muscle
Open myotomy alone	Myotomy of the cricopharyngeus muscle

SUGGESTED READINGS

Law R et al: *Zenker's diverticulum Clin Gastroenterol Hepatol* 12:1773-1782, 2014.

Manno M et al: Alternative endoscopic treatment of Zenker's diverticulum: a case series (with video), *Gastrointest Endosc* 79:168-170, 2014.

CHRONIC Rx

In patients not having surgery, treatment is directed toward any complications that may occur:

- Antibiotics for aspiration pneumonia
- H_2 antagonists for ulcerations that can develop within the diverticulum
- Botulinum toxin for temporary relief of dysphagia

DISPOSITION

- If left untreated, progressive enlargement of the diverticulum occurs.
- The risk of complications (e.g., aspiration pneumonia) increases with the size of the diverticulum.
- Postsurgical recurrence can occur (4%); however, these are usually asymptomatic.

REFERRAL

Any patient with dysphagia requires a gastroenterology consultation. A thoracic surgical, ENT, or head and neck surgeon may be consulted if surgery is considered.

COMMENTS

The association with cancer is rare (0.4%).

BASIC INFORMATION

DEFINITION

Zika virus infection is a mosquito-borne flavivirus that emerged as a global public health threat in 2016. The infection usually causes subclinical or mild flulike illness, but severe manifestations such microcephaly in babies born to infected mothers and Guillain-Barré syndrome in adults can occur. There is no treatment or vaccine at this time.

SYNONYMS

Zika fever
Zika virus disease

ICD-10CM CODES

A92.8	Other specified mosquito-borne viral fevers
A92.5	Zika virus disease

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Zika virus has been declared a public health emergency, with more than 20 countries and territories reporting local transmission of the virus in 2016.
- Brazil alone had reported more than 1.3 million people infected with the virus by June 2016.
- In the U.S.: By August 1, 2018, there were been 5716 symptomatic Zika virus disease cases reported. Of these, 5430 cases were in travelers returning from affected areas. There were 231 cases acquired through presumed local mosquito-borne transmission, (Florida and Texas); and 55 cases acquired through other routes: sexual transmission (52 cases), lab transmission (2 cases), and person-to-person through unknown contact (1 case). In U.S. territories (Puerto Rico, Virgin Islands, Guam), there have been 37,262 cases with the vast majority through local transmission.
- In terms of pregnant women and Zika: There have been more than 2000 cases in the U.S. and over 5000 cases in U.S. territories.
- It is thought that one in seven babies exposed in utero to the Zika virus may have been harmed by the infection: 9% of 1450 exposed babies studied at 1 yr of age had a neurodevelopmental issue: seizures, hearing problems, difficulties swallowing, cerebral palsy-like movements; 6% of the 1450 exposed babies had a birth defect: microcephaly, brain damage, ocular problems; and 1% of the babies exposed had both birth defects and neurodevelopmental concerns.

PEAK INCIDENCE: As a mosquito-borne disease, it is more common in warmer mos of the yr.

PREVALENCE: In an outbreak in Yap islands, 70% of the population was infected in a 13-wk period of time. Although transmission of Zika virus has declined in the Americas, outbreaks and infection clusters continue to occur in some regions, such as India and Southeast Asia.

RISK FACTORS: The virus can be transmitted in different ways:

- Most common is through the bite of an infected mosquito
- Maternal-fetal transmission
- Sexual contact: Vaginal, anal, and oral sex. Virus may persist in semen >2 mo
- Blood transfusion
- Organ or tissue transplant
- Laboratory exposure

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation period varies from 3 to 14 days.
- Some 80% of patients will be asymptomatic but can still subsequently develop complications.
- Symptomatic patients will present with:
  1. Mild fever, myalgia, headache
  2. Arthralgias (small joints of hands and feet)
  3. Abdominal pain
  4. Edema
  5. Lymphadenopathy
  6. Retroorbital pain, conjunctivitis
  7. Cutaneous macular-papular rash
- Complications of Zika virus infection:
  1. Neurologic complications: Meningoencephalitis, Guillain-Barré syndrome in adults, transverse myelitis, encephalomyelitis, and chronic inflammatory demyelinating polyneuropathy.
  2. Neonatal microcephaly: Patients may have mild developmental delays to cerebral palsy.
     a. In Brazil, the incidence of microcephaly increased to 2% to 8% but is still being studied.
     b. Degree of abnormalities may depend on trimester of pregnancy when the infection starts.
     c. 30% of infected pregnant woman may have adverse fetal findings, including fetal death, in utero growth delay with or without microcephaly, optic nerve damage, and ventricular calcifications.
- The Zika virus is neurotropic and can cross the blood-brain barrier.

ETIOLOGY

- Zika virus: A flavivirus in the same family as yellow fever virus, dengue virus, West Nile virus.
- First discovered in a febrile rhesus macaque monkey in the Zika forest in Uganda in 1947.
- First human cases discovered in 1954 in Nigeria but cases rare outside of Africa and Southeast Asia until 2007 when first large outbreak occurred in Yap (Micronesia) and then in French Polynesia (2013).
- Zika virus arrived in the Americas in May 2015 in Bahia, Brazil.
- An association with Guillain-Barré was noted in French Polynesia, but the association with microcephaly was first noted in September 2015 in Brazil.
- Vector for transmission is the *Aedes aegypti* mosquito, which lives in tropical and subtropical regions including southern U.S., and possibly the *Aedes albopictus* mosquito, which lives in temperate regions, including mid-Atlantic states in the U.S., as well as tropical areas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Viral causes of arthritis (Table E1):
  1. Dengue fever: Similar clinical presentation and transmitted by same mosquito
  2. Chikungunya virus: Similar presentation, albeit with high fever and intense pain in hands, feet, knees, and back; also transmitted by same mosquito
  3. Parvovirus
  4. Rubella
- Measles
- Leptospirosis
- Malaria
- Rickettsial infections: African tick bite fever and relapsing fever

WORKUP

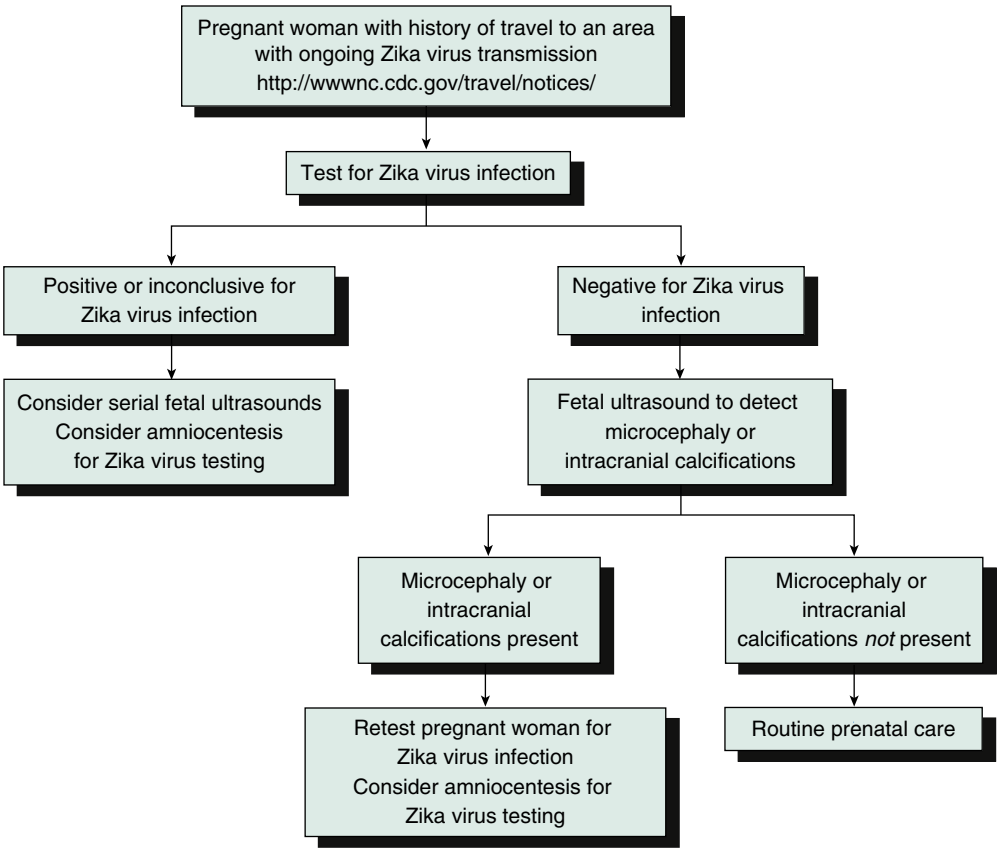
- Zika virus infection should be suspected in patients with typical clinical manifestations and a history of exposure to the virus via travel/residence in endemic area or sexual contact with a person from endemic area.
- Fig. E1 illustrates a testing algorithm for a pregnant woman with a history of travel to an area with ongoing Zika virus transmission.
- A testing algorithm for a pregnant woman with possible Zika exposure not residing in an area with active Zika virus transmission is described in Fig. E2.
- A testing algorithm for a pregnant woman residing in an area with active Zika virus transmission with or without clinical illness consistent with Zika virus disease is illustrated in Fig. E3.

TABLE E1 Clinical Features of Zika Virus Compared with Dengue and Chikungunya[a]

Features	Zika	Dengue	Chikungunya
Fever	+ to ++	+++	+++
Maculopapular rash	+++	+	++
Pruritus	++	–/+	–/+
Conjunctivitis	++	–	+/–
Arthralgia	++	+	+++
Myalgia	+	++	+
Headache	+	++	++
Facial edema	+/–	++	+
Palatal petechiae	+/–	++	+
Hemorrhage	–	++	–
Shock	–	+	–

Primarily adapted from a Centers for Disease Control and Prevention Presentation by Ingrid Rabe, "Zika Virus: What Clinicians Need to Know," a Clinician Outreach and Communication Activity (COCA) Call, Atlanta, GA, January 26, 2016.

[a]Note that one study of all three viruses of patients in Nicaragua suggested more similarities among the three viruses with regard to fever, conjunctivitis, arthralgia, and headache.



* Testing is recommended for pregnant women with clinical illness consistent with Zika virus disease, which includes two or more of the following signs or symptoms: acute onset of fever, maculopapular rash, arthralgia, or conjunctivitis during or within 2 weeks of travel. Testing includes Zika virus reverse transcription-polymerase chain reaction (RT-PCR), and Zika virus immunoglobulin M (IgM) and neutralizing antibodies on serum specimens (http://www.aphl.org/Materials/CDCMemo_Zika_Chik_Deng_Testing_011916.pdf). Because of the overlap of symptoms and areas where other viral illnesses are endemic, evaluation for dengue or chikungunya virus infection is also recommended.

† Testing can be offered to pregnant women without clinical illness consistent with Zika virus disease. If performed, testing should include Zika virus IgM, and if IgM test result is positive or indeterminate, neutralizing antibodies on serum specimens. Testing should be performed 2–12 weeks after travel.

§ Laboratory evidence of maternal Zika virus infection: (1) Zika virus RNA detected by RT-PCR in any clinical specimen; or (2) positive Zika virus IgM with confirmatory neutralizing antibody titers that are ≥4-fold higher than dengue virus neutralizing antibody titers in serum. Testing is considered inconclusive if Zika virus neutralizing antibody titers are <4-fold higher than dengue virus neutralizing antibody titers.

¶ Fetal ultrasounds might not detect microcephaly or intracranial calcifications until the late second or early third trimester of pregnancy.

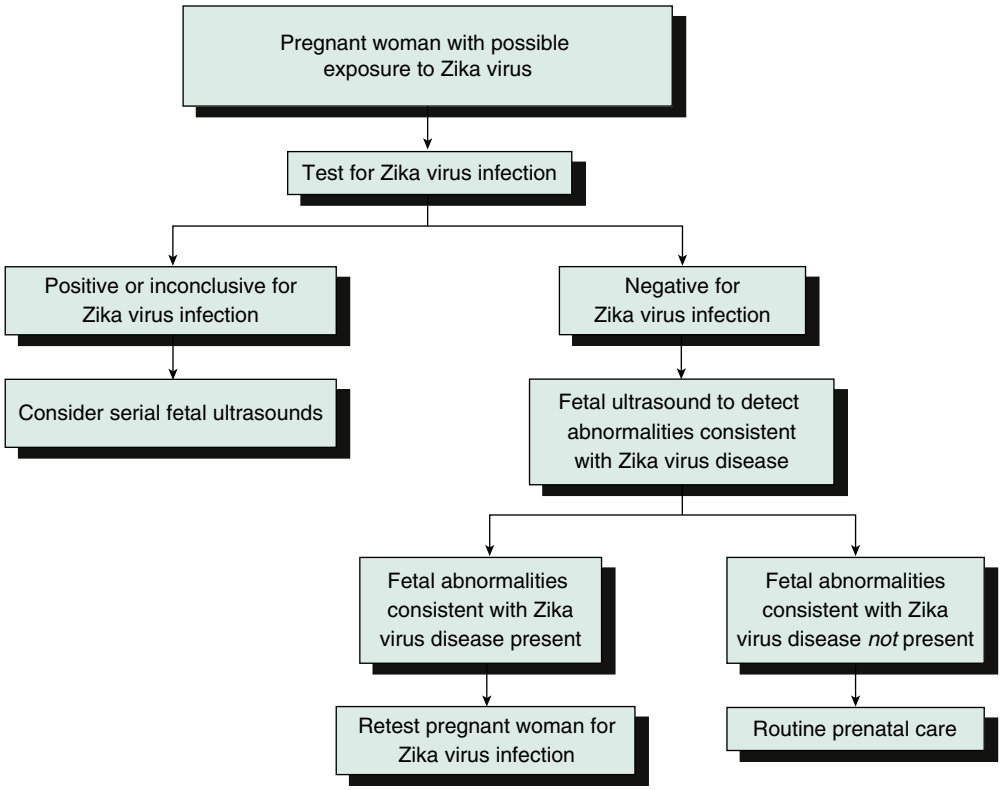
** Amniocentesis is not recommended until after 15 weeks of gestation. Amniotic fluid should be tested for Zika virus RNA by RT-PCR. The sensitivity and specificity of RT-PCR testing on amniotic fluid are not known.

FIG. E1 Updated interim guidance: Testing algorithm*,†,§,¶, for a pregnant woman with history of travel to an area with ongoing Zika virus transmission.** (From Oduyebo T et al: Update: interim guidelines for health care providers caring for pregnant women and women of reproductive age with possible Zika virus exposure—United States, 2016, MMWR 65(5):122-127, 2016, fig. 1 p. 124.)

- Box E1 summarizes recommended Zika virus laboratory testing for infants and children when indicated.
- Recommended clinical evaluation and laboratory testing for infants with possible congenital Zika virus infection is summarized in Box E2.
- Fig. E4 illustrates recommendations for the evaluation of infants with possible congenital Zika virus infection based on infant clinical findings.

LABORATORY TESTS

- Zika virus reverse transcriptase polymerase



* Testing is recommended for pregnant women with clinical illness consistent with Zika virus disease, including one or more of the following signs or symptoms: acute onset of fever, rash, arthralgia, or conjunctivitis during or within 2 weeks of travel or possible sexual exposure. Testing includes Zika virus reverse transcription-polymerase chain reaction (RTPCR), and Zika virus immunoglobulin M (IgM) and neutralizing antibodies on serum specimens. More information is available at http://www.aphl.org/Materials/CDCMemo_Zika_Chik_Deng_Testing_011916.pdf. Because of the overlap of symptoms and areas where other viral illnesses are endemic, evaluate for possible dengue or chikungunya virus infection.

† Testing can be offered to pregnant women without clinical illness consistent with Zika virus disease. If performed, testing should include Zika virus IgM, and if IgM test result is positive or indeterminate, neutralizing antibodies on serum specimens. Testing should be performed 2–12 weeks after travel.

§ Laboratory evidence of maternal Zika virus infection: (1) Zika virus RNA detected by RT-PCR in any clinical specimen; or (2) positive Zika virus IgM with confirmatory neutralizing antibody titers that are ≥4-fold higher than dengue virus neutralizing antibody titers in serum. Testing is considered inconclusive if Zika virus neutralizing antibody titers are <4-fold higher than dengue virus neutralizing antibody titers.

¶ Fetal abnormalities consistent with Zika virus disease include microcephaly, intracranial calcifications, and brain and eye abnormalities. Fetal ultrasounds might not detect abnormalities until late second or early third trimester of pregnancy

** Possible exposure to Zika virus includes travel to an area with active Zika virus transmission (http://wwwnc.cdc.gov/travel/notices), or sex (vaginal intercourse, anal intercourse, or fellatio) without a condom with a man who traveled to, or resided in, an area with active Zika virus transmission. Testing is not currently recommended for pregnant women with possible sexual exposure to Zika virus if both partners are asymptomatic.

FIG. E2 Updated interim guidance: Testing algorithm*,†,§,¶ for a pregnant woman with possible Zika virus exposure not residing in an area with active Zika virus transmission.** (From Petersen E et al: Update: interim guidelines for health care providers caring for pregnant women and women of reproductive age with possible Zika virus exposure—United States, 2016, *MMWR* 65(12):315-322, 2016, fig. 1 p. 319.)

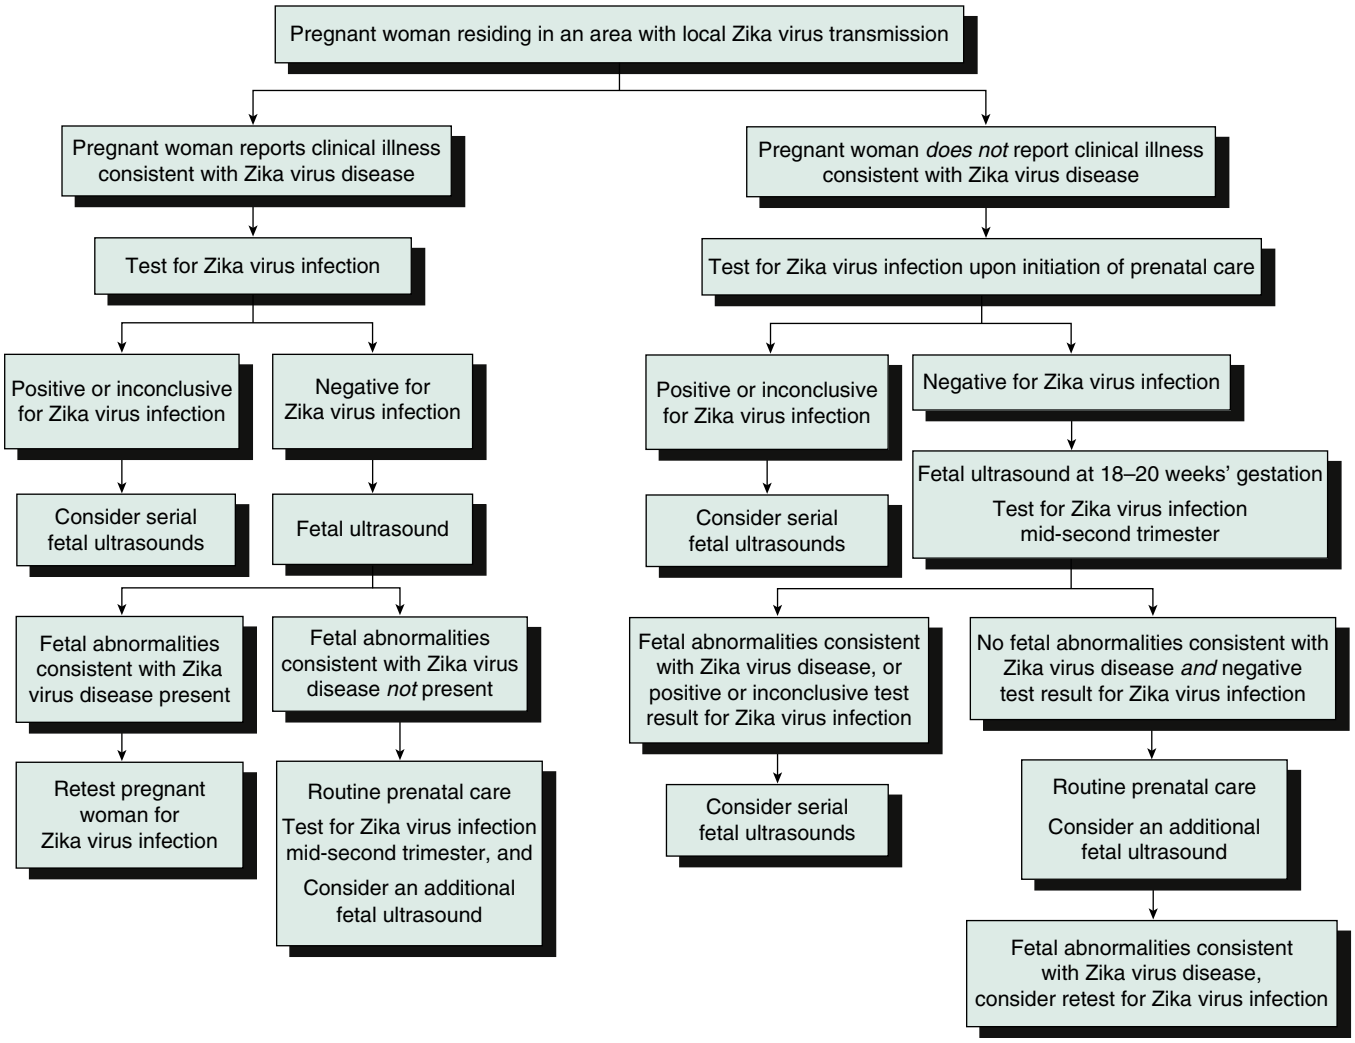
chain reaction (Zika RT-PCR) in serum or urine in acute infection

1. Serum: Only positive if viremic (3 to 7 days after start of symptoms)
2. Urine: Positive for up to 14 days after start of symptoms

- Zika serology: Zika virus IgM ELISA for patients presenting longer than 14 days of symptoms; Zika virus IgG ELISA
- It should be noted that there is cross-reactivity with other flaviviruses; dengue and yellow fever can lead to false positives

IMAGING STUDIES

- Fetal ultrasound is used to screen for fetal Zika virus infection complications.
- Fetal abnormalities may be seen as early as 18 to 20 wk of gestation but more



* Tests for pregnant women with clinical illness consistent with Zika virus disease include Zika virus reverse transcription-polymerase chain reaction (RT-PCR), and Zika virus immunoglobulin M (IgM) and neutralizing antibodies on serum specimens. More information is available at http://www.aphl.org/Materials/CDCMemo_Zika_Chik_Deng_Testing_011916.pdf. Because of the overlap of symptoms and areas where other viral illnesses are endemic, evaluate for possible dengue or chikungunya virus infection. If chikungunya or dengue virus RNA is detected, treat in accordance with existing guidelines. Timely recognition and supportive treatment for dengue virus infections can substantially lower the risk of medical complications and death. Repeat Zika virus testing during pregnancy is warranted if clinical illness consistent with Zika virus disease develops later in pregnancy.

† Testing can be offered to pregnant women without clinical illness consistent with Zika virus disease. If performed, testing should include Zika virus IgM, and if IgM test result is positive or indeterminate, neutralizing antibodies on serum specimens. Results from serologic testing are challenging to interpret in areas where residents have had previous exposure to other flaviviruses (e.g., dengue, yellow fever) because of cross-reactivity with other flaviviruses.

§ Laboratory evidence of maternal Zika virus infection: (1) Zika virus RNA detected by RT-PCR in any clinical specimen; or (2) positive Zika virus IgM with confirmatory neutralizing antibody titers that are ≥4-fold higher than dengue virus neutralizing antibody titers in serum. Testing would be considered inconclusive if Zika virus neutralizing antibody titers are <4-fold higher than dengue virus neutralizing antibody titer.

¶ Fetal abnormalities consistent with Zika virus disease include microcephaly, intracranial calcifications, and brain and eye abnormalities. Fetal ultrasounds might not detect abnormalities until late second or early third trimester of pregnancy.

** http://wwwnc.cdc.gov/travel/notices/. Local health officials should determine when to implement testing of asymptomatic pregnant women based on information about levels of Zika virus transmission and laboratory capacity.

†† Clinical illness is consistent with Zika virus disease if one or more signs or symptoms (acute onset of fever, rash, arthralgia, or conjunctivitis) are present.

FIG. E3 Updated interim guidance: Testing algorithm*,†,§,¶ for a pregnant woman residing in an area with active Zika virus transmission, with or without clinical illness†† consistent with Zika virus disease.** (From Petersen E et al: Update: interim guidelines for health care providers caring for pregnant women and women of reproductive age with possible Zika virus exposure—United States, 2016, *MMWR* 65(12):315-322, 2016, fig. 2 p. 320.)

BOX E1 Recommended Zika Virus Laboratory Testing for Infants and Children When Indicated*,†,‡

For possible congenital Zika virus infection

- Test infant serum for Zika virus RNA, Zika virus immunoglobulin M (IgM) and neutralizing antibodies, and dengue virus IgM and neutralizing antibodies. The initial sample should be collected either from the umbilical cord or directly from the infant within 2 days of birth, if possible.
- If cerebrospinal fluid is obtained for other studies, test for Zika virus RNA, Zika virus IgM and neutralizing antibodies, and dengue virus IgM and neutralizing antibodies.
- Consider histopathologic evaluation of the placenta and umbilical cord with Zika virus immunohistochemical staining on fixed tissue and Zika virus reverse transcription-polymerase chain reaction (RT-PCR) on fixed and frozen tissue.
- If not already performed during pregnancy, test mother's serum for Zika virus IgM and neutralizing antibodies, and dengue virus IgM and neutralizing antibodies.

For possible acute Zika virus disease

- If symptoms have been present for <7 days, test serum (and, if obtained for other reasons, cerebrospinal fluid) for Zika virus RNA by RT-PCR.
- If Zika virus RNA is not detected and symptoms have been present for ≥4 days, test serum (and, if obtained for other reasons, cerebrospinal fluid) for Zika virus IgM and neutralizing antibodies, and dengue virus IgM and neutralizing antibodies.

*Indications for testing for congenital infection include (1) an infant with microcephaly or intracranial calcifications born to a woman who traveled to or resided in an area with Zika virus transmission while she was pregnant or (2) an infant born to a mother with a positive or inconclusive test result for Zika virus infection.
†Indications for testing during acute disease include infants and children <18 yr who (1) traveled to or resided in an affected area within the past 2 wk and (2) have ≥2 of the following manifestations: fever, rash, conjunctivitis, or arthralgia. Infants in the first 2 wk of life (1) whose mothers have traveled to or resided in an affected area within 2 wk of delivery and (2) have ≥2 of the following manifestations: fever, rash, conjunctivitis, or arthralgia.
‡More information on laboratory testing for Zika virus infection is available at www.cdc.gov/zika/state-labs/index.html

BOX E2 Recommended Clinical Evaluation and Laboratory Testing for Infants with Possible Congenital Zika Virus Infection

For all infants with possible congenital Zika virus infection, perform the following:

- Comprehensive physical examination, including careful measurement of occipitofrontal circumference, length, weight, and assessment of gestational age.
- Evaluation for neurologic abnormalities, dysmorphic features, splenomegaly, hepatomegaly, and rash or other skin lesions. Full-body photographs and photographic documentation of any rash, skin lesions, or dysmorphic features should be performed. If an abnormality is noted, consultation with an appropriate specialist is recommended.
- Cranial ultrasound, unless prenatal ultrasound results from third trimester demonstrated no abnormalities of the brain.
- Evaluation of hearing by evoked otoacoustic emissions testing or auditory brainstem response testing, either before discharge from the hospital or within 1 mo after birth. Infants with abnormal initial hearing screens should be referred to an audiologist for further evaluation.
- Ophthalmologic evaluation, including examination of the retina, either before discharge from the hospital or within 1 mo after birth. Infants with abnormal initial eye evaluation should be referred to a pediatric ophthalmologist for further evaluation.
- Other evaluations specific to the infant's clinical presentation.

For infants with microcephaly or intracranial calcifications, additional evaluation includes the following:

- Consultation with a clinical geneticist or dysmorphologist.
- Consultation with a pediatric neurologist to determine appropriate brain imaging and additional evaluation (e.g., ultrasound, computerized tomography scan, magnetic resonance imaging, and electroencephalogram).
- Testing for other congenital infections such as syphilis, toxoplasmosis, rubella, cytomegalovirus infection, lymphocytic choriomeningitis virus infection, and herpes simplex virus infections. Consider consulting a pediatric infectious disease specialist.
- Complete blood count with platelet count and liver function and enzyme tests, including alanine aminotransferase, aspartate aminotransferase, and bilirubin.
- Consideration of genetic and other teratogenic causes based on additional congenital anomalies that are identified through clinical examination and imaging studies.

Adapted from Staples JE et al: Interim guidelines for the evaluation and testing of infants with possible congenital Zika virus infection—United States, *MMWR* 65(3):63-67, 2016.

likely detected in late second and early third trimester.
- Fetal microcephaly is described as a head circumference >3 standard deviations below the mean for gestational age by the Society for Maternal-Fetal Medicine and <third percentile for gestational age by the Centers for Disease Control and Prevention (CDC).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Rest and hydration

ACUTE GENERAL Rx

- Acetaminophen can be used for fever but not aspirin or NSAIDs until dengue virus has been ruled out. Aspirin increases risk of hemorrhage, and NSAIDs should not be used in pregnancy. Aspirin should be avoided in children due to risk of Reye syndrome.
- Antihistamines can be used to control rash in patients with a rash.
- At this time, there is no specific antiviral agent.

REFERRAL

To an expert in obstetrics and gynecology to evaluate a pregnant woman who may have been exposed to the Zika virus. Recommended long-term follow-up for infants with possible congenital Zika virus infection are summarized in Box E3.

PEARLS & CONSIDERATIONS

- The *Aedes* mosquitos can also transmit dengue and chikungunya viruses.
- CDC maintains a service to help physicians deal with a pregnant woman and infants exposed to the Zika virus: 1-800-CDC-INFO.
- Vaccine development is ongoing but no currently available vaccine.

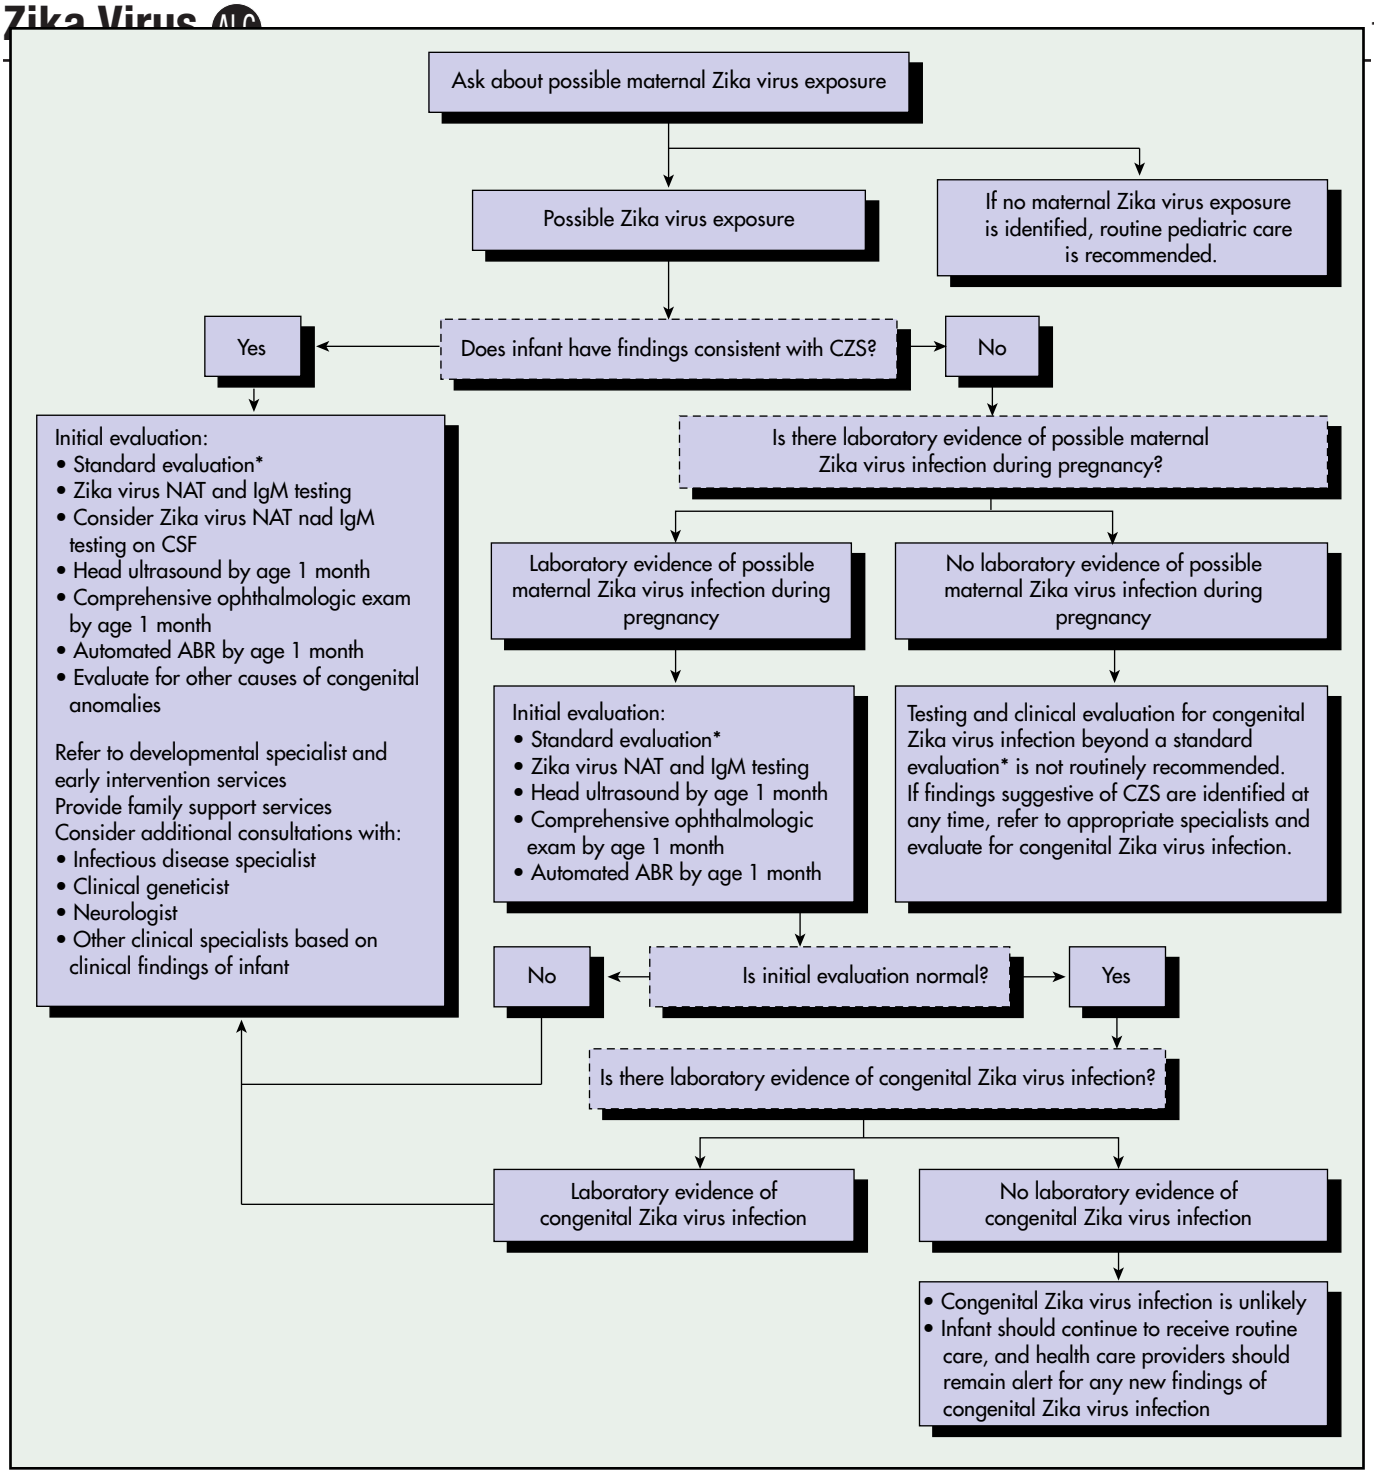


FIG. E4 Recommendations for the evaluation of infants with possible congenital Zika virus infection based on infant clinical findings,*,† maternal testing results,§,¶ and infant testing results,†† — U.S., October 2017.** *All infants should receive a standard evaluation at birth and at each subsequent well-child visit by their health care providers including (1) comprehensive physical examination, including growth parameters and (2) age-appropriate vision screening and developmental monitoring and screening using validated tools. Infants should receive a standard newborn hearing screen at birth, preferably using auditory brainstem response. †Automated ABR by age 1 mo if newborn hearing screen passed but performed with otoacoustic emission methodology. §Laboratory evidence of possible Zika virus infection during pregnancy is defined as (1) Zika virus infection detected by a Zika virus RNA NAT on any maternal, placental, or fetal specimen (referred to as NAT-confirmed); or (2) diagnosis of Zika virus infection, timing of infection cannot be determined or unspecified flavivirus infection, timing of infection cannot be determined by serologic tests on a maternal specimen (i.e., positive/equivocal Zika virus IgM and Zika virus PRNT titer ≥10, regardless of dengue virus PRNT value; or negative Zika virus IgM, and positive or equivocal dengue virus IgM, and Zika virus PRNT titer ≥10, regardless of dengue virus PRNT titer). The use of PRNT for confirmation of Zika virus infection, including in pregnant women, is not routinely recommended in Puerto Rico (https://www.cdc.gov/zika/laboratories/lab-guidance.html). ¶This group includes women who were never tested during pregnancy as well as those whose test result was negative because of issues related to timing or sensitivity and specificity of the test. Because the latter issues are not easily discerned, all mothers with possible exposure to Zika virus during pregnancy who do not have laboratory evidence of possible Zika virus infection, including those who tested negative with currently available technology, should be considered in this group. **Laboratory testing of infants for Zika virus should be performed as early as possible, preferably within the first few days after birth, and includes concurrent Zika virus NAT in infant serum and urine, and Zika virus IgM testing in serum. If CSF is obtained for other purposes, Zika virus NAT and Zika virus IgM testing should be performed on CSF. ††Laboratory evidence of congenital Zika virus infection includes a positive Zika virus NAT or a nonnegative Zika virus IgM with confirmatory neutralizing antibody testing, if PRNT confirmation is performed. *ABR,* Auditory brainstem response; *CSF,* cerebrospinal fluid; *CZS,* congenital Zika syndrome; *IgM,* immunoglobulin M; *NAT,* nucleic acid test; *PRNT,* plaque reduction neutralization test. (From Adebanjo T et al: Update: interim guidance for the diagnosis, evaluation, and management of infants with possible congenital Zika virus infection—United States, 2017, *MMWR* 66(41): 1089-1099, 2017, fig. 1 p. 1093.)

BOX E3 Recommended Long-Term Follow-up for Infants with Possible Congenital Zika Virus Infection

For all infants with possible congenital Zika virus infection, recommended long-term follow-up:

- Report case to state, territorial, or local health department and monitor for additional guidance as it is released.
- Consider conducting additional hearing screen at age 6 mo. Refer any child with developmental delay for an audiologic evaluation. Ensure that appropriate follow-up of abnormal newborn hearing screening has occurred.
- Carefully evaluate occipitofrontal circumference and developmental characteristics and milestones throughout the first yr of life, in consultation with appropriate medical specialists (e.g., pediatric neurology, developmental and behavioral pediatrics, physical and speech therapy).

Adapted from Staples JE et al: Interim guidelines for the evaluation and testing of infants with possible congenital Zika virus infection—United States, *MMWR* 65(3):63-67, 2016.

BOX E4 Recommendations for Counseling Persons in Areas of Active Zika Virus Transmission Interested in Attempting Conception

Assess risk of Zika virus exposure

Environment

- Air conditioning, window screens in home
- Work environment
- Residence in area with high mosquito density
- Level of Zika virus transmission in the local area

Personal measures to prevent mosquito bites

- Protective clothing
- Use of EPA-registered insect repellent
- Emptying/removing standing water in containers

Personal measures to prevent sexual transmission

- Willingness to use condoms or abstain from sex throughout pregnancy

Discuss Zika virus infection in pregnancy

- Signs/symptoms of Zika virus disease
- Possible adverse consequences of Zika virus infection during pregnancy
- Unknown duration of epidemic

Explore reproductive life plan

- Fertility
- Age
- Reproductive history
- Medical history
- Personal values, preferences

Discuss risks/benefits of pregnancy at this time with woman and her partner

- If pregnancy not desired now, discuss contraceptive options.

Adapted from Adebanjo T et al: Update: Interim guidance for the diagnosis, evaluation, and management of infants with possible congenital Zika virus infection—United States, *MMWR* 66(41):1089-1099, 2017.

BOX E5 Recommendations for Prevention of Sexual Transmission of Zika Virus for Couples in Which a Man Has Traveled to or Resides in an Area with Active Zika Virus Transmission

Couples in which a woman is pregnant

- Couples in which a woman is pregnant should use condoms consistently and correctly or abstain from sex for the duration of the pregnancy.

Other couples concerned about sexual transmission*

- Couples in which a man had confirmed Zika virus infection or clinical illness consistent with Zika virus disease should consider using condoms or abstaining from sex for at least 6 mo after onset of illness.
- Couples in which a man traveled to an area with active Zika virus transmission but did not develop symptoms of Zika virus disease should consider using condoms or abstaining from sex for at least 8 wk after departure from the area.
- Couples in which a man resides in an area with active Zika virus transmission but has not developed symptoms of Zika virus disease might consider using condoms or abstaining from sex while active transmission persists.

*Couples who do not desire pregnancy should use the most effective contraception methods that can be used correctly and consistently in addition to condoms, which also reduce the risk for sexually transmitted infections. Couples planning conception have a number of factors to consider, which are discussed in more detail in the following: Petersen EE et al: Update: interim guidance for health care providers caring for women of reproductive age with possible Zika virus exposure—United States, 2016, *MMWR* 2016.
From Oduyebo T et al: Update: interim guidance for health care providers caring for pregnant women with possible Zika virus exposure—United States, *MMWR* 66(29):781-793, 2017.

- Aerial spraying with EPA-registered insecticides has been a strategy implemented in the Florida outbreak, along with other mosquito-control strategies.

COMMENTS

Zika virus is already impacting blood donations for people who have traveled to affected area or live in affected areas. Travelers may need to postpone donations for at least 28 days. New guidelines by the U.S. Food and Drug Administration (FDA) call for testing blood donors in areas where active Zika virus transmission has occurred.

PREVENTION

- Wear long-sleeved shirts, pants, and hat.
- Insect repellents: Apply to exposed skin in daylight hours when *Aedes* mosquitos are most active:
  1. DEET: Diethyltoluamide 20% to 50% concentration
  2. Icaridin in at least 20% concentration
  3. Lemon eucalyptus extract in at least 30% concentration
- Clothing can be treated with permethrin soak or 1% spray.
- Do not use insect repellents on babies younger than 2 mo and avoid lemon eucalyptus on children younger than 3 yr.
- Recommendations for counseling persons in areas of active Zika virus transmission interested in attempting conception are summarized in Box E4.
- Recommendations for prevention of sexual transmission of Zika virus for couples in which a man has traveled to or resides in an area with active Zika virus transmission are summarized in Box E5.

PATIENT & FAMILY EDUCATION

- Both *Aedes aegypti* and *Aedes albopictus* are daytime biters, so protection is essential during those hours.
- In a recent study evaluating persistence of Zika virus in body fluids, in 95% of infected men, Zika RNA was cleared from semen after approximately 4 mo. Men who have traveled to areas where Zika virus is present and have developed symptomatic disease should abstain from sexual contact or use a condom for at least 3 mo afterward.
- Recommendations for counseling persons who live in areas of active Zika virus transmission and are interested in attempting conception.

ABDOMINAL DISTENTION

ICD-10CM #		
	R14.0	Abdominal distension (gaseous)

NONMECHANICAL OBSTRUCTION

Excessive intraluminal gas.
Intraabdominal infection.
Trauma.
Retroperitoneal irritation (renal colic, neoplasms, infections, hemorrhage).
Vascular insufficiency (thrombosis, embolism).
Mechanical ventilation.
Extraabdominal infection (sepsis, pneumonia, empyema, osteomyelitis of spine).
Metabolic/toxic abnormalities (hypokalemia, uremia, lead poisoning).
Chemical irritation (perforated ulcer, bile, pancreatitis).
Peritoneal inflammation.
Severe pain, pain medications.

MECHANICAL OBSTRUCTION

Neoplasm (intraluminal, extraluminal).
Adhesions, endometriosis.
Infection (intraabdominal abscess, diverticulitis).
Gallstones.
Foreign body, bezoars.
Pregnancy.
Hernias.
Volvulus.
Stenosis at surgical anastomosis, radiation stenosis.
Fecaliths.
Inflammatory bowel disease.
Gastric outlet obstruction.
Hematoma.
Other: parasites, superior mesenteric artery (SMA) syndrome, pneumatosis intestinalis, annular pancreas, Hirschsprung disease, intussusception, meconium.

ABDOMINAL PAIN, ADOLESCENCE[58]

ICD-10CM #		
	R10.817	Generalized abdominal tenderness
	R10.827	Generalized rebound abdominal tenderness

Acute gastroenteritis.
Irritable bowel syndrome (IBS).
Anxiety.
Mittelschmerz.
Appendicitis.
Inflammatory bowel disease.
Peptic ulcer disease (PUD).
Cholecystitis.
Neoplasm.
Diabetic ketoacidosis.
Functional abdominal pain.
Pelvic inflammatory disease (PID).
Pregnancy.
Pyelonephritis.
Renal stone.
Trauma.

ABDOMINAL PAIN, CHILDHOOD[58]

ICD-10CM #		
	R10.817	Generalized abdominal tenderness
	R10.827	Generalized rebound abdominal tenderness

Acute gastroenteritis.
Appendicitis.
Constipation.
Cholecystitis, acute.
Intestinal obstruction.
Pancreatitis.
Neoplasm.
Inflammatory bowel disease.
Other:
- Functional abdominal pain.
- Pyelonephritis.
- Pneumonia.
- Diabetic ketoacidosis.
- Heavy metal poisoning.
- Sickle cell crisis.
- Trauma.
- Anxiety.
- Sexual abuse.

ABDOMINAL PAIN, CHRONIC LOWER[86]

ICD-10CM #		
	R10.814	Left lower quadrant abdominal tenderness
	R10.824	Left lower quadrant rebound abdominal tenderness
	R10.813	Right lower quadrant abdominal tenderness
	R10.823	Right lower quadrant rebound abdominal tenderness
	R10.30	Lower abdominal pain, unspecified

ORGANIC DISORDERS

Common
Gynecologic disease.
Lactase deficiency.
Diverticulitis/diverticulosis.
Crohn disease.
Intestinal obstruction.
Uncommon
Chronic intestinal pseudoobstruction.
Mesenteric ischemia.
Malignancy (e.g., ovarian carcinoma).
Abdominal wall pain.
Spinal disease.
Testicular disease.
Metabolic diseases (e.g., diabetes mellitus, familial Mediterranean fever, C1 esterase deficiency [angioneurotic edema], porphyria, lead poisoning, tabes dorsalis, renal failure).

FUNCTIONAL DISORDERS

Common
Irritable bowel syndrome.
Functional abdominal bloating.
Uncommon
Functional abdominal pain.

ABDOMINAL PAIN, DIFFUSE

ICD-10CM #		
	R10.817	Generalized abdominal tenderness
	R10.827	Generalized rebound abdominal tenderness

Early appendicitis.
Aortic aneurysm.
Gastroenteritis.
Intestinal obstruction.
Diverticulitis.
Peritonitis.
Mesenteric insufficiency or infarction.
Pancreatitis.
Inflammatory bowel disease.
Irritable bowel.
Mesenteric adenitis.
Metabolic: toxins, lead poisoning, uremia, drug overdose, diabetic ketoacidosis (DKA), heavy metal poisoning.
Sickle cell crisis.
Pneumonia (rare).
Trauma.
Urinary tract infection, PID.
Other: anxiety, acute intermittent porphyria, tabes dorsalis, periarteritis nodosa, Henoch-Schönlein purpura, adrenal insufficiency.

ABDOMINAL PAIN, EPIGASTRIC

ICD-10CM #		
	R10.816	Epigastric abdominal tenderness
	R10.826	Epigastric rebound abdominal tenderness

Gastric: PUD, gastric outlet obstruction, gastric ulcer.
Duodenal: PUD, duodenitis.
Biliary: cholecystitis, cholangitis, biliary dyskinesia.
Hepatic: hepatitis.
Pancreatic: pancreatitis.
Intestinal: high small bowel obstruction, early appendicitis.
Cardiac: angina, MI, pericarditis.
Pulmonary: pneumonia, pleurisy, pneumothorax.
Subphrenic abscess.
Vascular: dissecting aneurysm, mesenteric ischemia.
Psychiatric: anxiety.

ABDOMINAL PAIN, EXTRAABDOMINAL AND SYSTEMIC CAUSES[26]

ICD-10CM #		
	R10.817	Generalized abdominal tenderness

EXTRAABDOMINAL AND SYSTEMIC CAUSES OF ACUTE ABDOMINAL PAIN

Cardiac
Endocarditis.
Heart failure.
Myocardial ischemia and infarction.
Myocarditis.
Thoracic
Empyema.
Esophageal rupture (Boerhaave syndrome).
Esophageal spasm.
Esophagitis.
Pleurodynia (Bornholm disease).
Pneumonitis.
Pneumothorax.
Pulmonary embolism and infarction.
Hematologic
Acute leukemia.
Hemolytic anemia.
Henoch-Schönlein purpura.
Sickle cell disease.
Metabolic
Acute adrenal insufficiency (Addison disease).
Diabetes mellitus (especially with ketoacidosis).
Hyperlipidemia.
Hyperparathyroidism.
Hypersensitivity reactions (e.g., to insect bites, reptile venoms).
Lead poisoning.
Porphyria.
Toxins.
Uremia.
Infections
Herpes zoster.
Osteomyelitis.
Typhoid fever.
Neurologic
Abdominal epilepsy.
Radiculopathy, spinal cord or peripheral nerve tumors, degenerative arthritis of spine, herniated vertebral disk.
Tabes dorsalis.
Miscellaneous
Angioedema.
Familial Mediterranean fever.
Heat stroke.
Muscle contusion, hematoma, tumor.
Narcotic withdrawal.
Psychiatric disorders.

ABDOMINAL PAIN, INFANCY[58]

ICD-10CM #		
	R10.817	Generalized abdominal tenderness
	R10.827	Generalized rebound abdominal tenderness

Acute gastroenteritis.
Appendicitis.
Intussusception.
Volvulus.
Meckel diverticulum.
Other: colic, trauma.

ABDOMINAL PAIN, LEFT LOWER QUADRANT

ICD-10CM #		
	R10.814	Left lower quadrant abdominal tenderness
	R10.824	Left lower quadrant rebound abdominal tenderness

Intestinal: diverticulitis, diverticulosis, intestinal obstruction, perforated ulcer, inflammatory bowel disease, perforated descending colon, inguinal hernia, neoplasm, appendicitis.
Reproductive: ectopic pregnancy, ovarian cyst, torsion of ovarian cyst, tuboovarian abscess, mittelschmerz, endometriosis, seminal vesiculitis.
Renal: renal or ureteral calculi, pyelonephritis, neoplasm.
Vascular: leaking aortic aneurysm.
Psoas abscess.
Trauma.

ABDOMINAL PAIN, LEFT UPPER QUADRANT

ICD-10CM #		
	R19.02	Left upper quadrant abdominal swelling, mass, and lump

Gastric: PUD, gastritis, pyloric stenosis, hiatal hernia.
Pancreatic: pancreatitis, neoplasm, stone in pancreatic duct or ampulla.
Cardiac: MI, angina pectoris.
Splenic: splenomegaly, ruptured spleen, splenic abscess, splenic infarction.
Renal: calculi, pyelonephritis, neoplasm.
Pulmonary: pneumonia, empyema, pulmonary infarction.
Vascular: ruptured aortic aneurysm.
Cutaneous: herpes zoster.
Trauma.
Intestinal: high fecal impaction, perforated colon, diverticulitis.

ABDOMINAL PAIN, NONSURGICAL CAUSES

ICD-10CM #		
	R19.8	Other specified symptoms and signs involving the digestive system and abdomen
	R10.817	Generalized abdominal tenderness

Irritable bowel syndrome.
Urinary tract infection, pyelonephritis, salpingitis, PID.
Gastroenteritis, gastritis, peptic ulcer.
Diverticular spasm.
Hepatitis, mononucleosis.
Pancreatitis.
Inferior wall myocardial infarction.
Basilar pneumonia, pulmonary embolism.
Diabetic ketoacidosis.
Strain or hematoma of rectus muscle.
Ruptured Graafian follicle.
Herpes zoster.
Nerve root compression.
Sickle cell crisis.
Acute adrenal insufficiency.
Other: acute porphyria, familial Mediterranean fever, tabes dorsalis, anxiety, sexual abuse.

ABDOMINAL PAIN, PERIUMBILICAL

ICD-10CM #		
	R10.815	Periumbilic abdominal tenderness
	R10.825	Periumbilic rebound abdominal tenderness

Intestinal: small bowel obstruction or gangrene, early appendicitis.
Vascular: mesenteric thrombosis, dissecting aortic aneurysm.
Pancreatic: pancreatitis.
Metabolic: uremia, DKA.
Trauma.

ABDOMINAL PAIN, POORLY LOCALIZED[58]

ICD-10CM #		
	R10.819	Abdominal tenderness, unspecified site

EXTRAABDOMINAL

Metabolic
DKA, acute intermittent porphyria, hyperthyroidism, hypothyroidism, hypercalcemia, hypokalemia, uremia, hyperlipidemia, hyperparathyroidism.
Hematologic
Sickle cell crisis, leukemia or lymphoma, Henoch-Schönlein purpura.
Infectious
Infectious mononucleosis, Rocky Mountain spotted fever, acquired immunodeficiency syndrome (AIDS), streptococcal pharyngitis (in children), herpes zoster.
Drugs and Toxins
Heavy metal poisoning, black widow spider bites, withdrawal syndromes, mushroom ingestion.
Referred Pain
Pulmonary: pneumonia, pulmonary embolism, pneumothorax.
Cardiac: angina, MI, pericarditis, myocarditis.
Genitourinary: prostatitis, epididymitis, orchitis, testicular torsion.
Musculoskeletal: rectus sheath hematoma.
Functional
Somatization disorder, malingering, hypochondriasis, Munchausen syndrome.

INTRAABDOMINAL

Early appendicitis, gastroenteritis, peritonitis, pancreatitis, abdominal aortic aneurysm, mesenteric insufficiency or infarction, intestinal obstruction, volvulus, ulcerative colitis.

ABDOMINAL PAIN, POST-CHOLECYSTECTOMY[26]

ICD-10CM #	R10.817	Generalized abdominal tenderness

CAUSES OF ABDOMINAL PAIN AFTER CHOLECYSTECTOMY

Biliary Causes
Biliary stricture.
Biliary tract malignancy.
Choledocholithiasis.
Choledochocele.
Cystic duct remnant.
SOD.

Pancreatic Causes
Pancreatitis.
Pseudocyst.
Malignancy.

Other GI Disorders
Esophageal motor disorders.
GERD.
Intestinal malignancy.
Intraabdominal adhesions.
IBS.
Mesenteric ischemia.
PUD.

Extraintestinal Disorders
Coronary artery disease.
Intercostal neuritis.
Neurologic disorders.
Psychiatric disorders.
Wound neuroma.

ABDOMINAL PAIN, PREGNANCY

ICD-10CM #	R10.817	Generalized abdominal tenderness
	R10.827	Generalized rebound abdominal tenderness

GYNECOLOGIC (GESTATIONAL AGE IN PARENTHESES)

Miscarriage	(<20 wk; 80% <12 wk)
Septic abortion	(<20 wk)
Ectopic pregnancy	(<14 wk)
Corpus luteum cyst rupture	(<12 wk)
Ovarian torsion	(especially <24 wk)
Pelvic inflammatory disease	(<12 wk)
Chorioamnionitis	(>16 wk)
Abruptio placentae	(>16 wk)

NONGYNECOLOGIC

Appendicitis	(Throughout)
Cholecystitis	(Throughout)
Hepatitis	(Throughout)
Pyelonephritis	(Throughout)
Preeclampsia	(>20 wk)

ABDOMINAL PAIN, RIGHT LOWER QUADRANT

ICD-10CM #	R10.813	Right lower quadrant abdominal tenderness
	R10.823	Right lower quadrant rebound abdominal tenderness

Intestinal: acute appendicitis, regional enteritis, incarcerated hernia, cecal diverticulitis, intestinal obstruction, perforated ulcer, perforated cecum, Meckel diverticulitis.
Reproductive: ectopic pregnancy, ovarian cyst, torsion of ovarian cyst, salpingitis, tuboovarian abscess, mittelschmerz, endometriosis, seminal vesiculitis.
Renal: renal and ureteral calculi, neoplasms, pyelonephritis.
Vascular: leaking aortic aneurysm.
Cutaneous: herpes zoster.
Psoas abscess.
Trauma.
Cholecystitis.

ABDOMINAL PAIN, RIGHT UPPER QUADRANT

ICD-10CM #	R10.811	Right upper quadrant abdominal tenderness
	R10.821	Right upper quadrant rebound abdominal tenderness

Biliary: calculi, infection, inflammation, neoplasm.
Hepatic: hepatitis, abscess, hepatic congestion, neoplasm, trauma.
Gastric: PUD, pyloric stenosis, neoplasm, alcoholic gastritis, hiatal hernia.
Pancreatic: pancreatitis, neoplasm, stone in pancreatic duct or ampulla.
Renal: calculi, infection, inflammation, neoplasm, rupture of kidney.
Pulmonary: pneumonia, pulmonary infarction, right-sided pleurisy.
Intestinal: retrocecal appendicitis, intestinal obstruction, high fecal impaction, diverticulitis.
Cardiac: myocardial ischemia (particularly involving the inferior wall), pericarditis.
Cutaneous: herpes zoster.
Trauma.
Fitz-Hugh-Curtis syndrome (perihepatitis).

ABDOMINAL PAIN, RIGHT UPPER QUADRANT, DIFFERENTIAL DIAGNOSIS IN PREGNANCY[30]

ICD-10CM #	R10.811	Right upper quadrant abdominal tenderness
	R10.821	Right upper quadrant rebound abdominal tenderness

DIFFERENTIAL DIAGNOSIS OF RIGHT UPPER QUADRANT ABDOMINAL PAIN DURING PREGNANCY

Hepatic Disorders:
Hepatitis.
Hepatic vascular engorgement.
Hepatic hematoma.
Hepatic malignancy.

Biliary Tract Disease:
Biliary colic.
Choledocholithiasis.
Cholangitis.
Cholecystitis.

Diseases Related to Pregnancy:
Preeclampsia or eclampsia.
Hemolysis, elevated liver enzymes, and low platelet count (HELLP) syndrome.
Acute fatty liver of pregnancy.
Hepatic hemorrhage or rupture.

Renal Disorders:
Pyelonephritis.
Nephrolithiasis.

Gastrointestinal Disorders:
Peptic ulcer disease.
Perforated duodenal ulcer.

Other Conditions in RUQ:
Rib fracture.
Shingles.

Referred Pain from Other Organ Disease:
Pneumonia.
Pulmonary embolus or infarct.
Pleural effusion.
Radiculopathy.
Inferior wall myocardial infarction.
Colon cancer.

ABDOMINAL PAIN, SUPRAPUBIC

ICD-10CM #	R10.30	Lower abdominal pain, unspecified

Intestinal: colon obstruction or gangrene, diverticulitis, appendicitis.
Reproductive system: ectopic pregnancy, mittelschmerz, torsion of ovarian cyst, PID, salpingitis, endometriosis, rupture of endometrioma.
Cystitis, rupture of urinary bladder.

ABDOMINAL WALL MASSES[86]

ICD-10CM #	R19.00	Intraabdominal and pelvic swelling, mass and lump, unspecified site

LUMPS ARISING IN THE SKIN AND SUBCUTANEOUS FAT (THAT COULD OCCUR ANYWHERE ON THE BODY)

Lipoma.
Sebaceous cyst.

LUMPS ARISING IN THE SKIN AND SUBCUTANEOUS FAT (SPECIFIC TO THE ANTERIOR ABDOMINAL WALL)

Tumor nodule of the umbilicus (secondary to the intraperitoneal malignancy, also called *Sister Mary Joseph nodule*).

LUMPS ARISING IN THE FASCIA AND MUSCLE

Rectus sheath hematoma (usually painful).
Desmoid tumor (associated with Gardner syndrome).

HERNIA

Incisional:	It has an overlying scar. The sac may be very much larger than the neck of the hernia.
Umbilical:	The hernia is through the umbilical scar. Those presenting at birth commonly resolve in the first years of life.
Paraumbilical:	The neck is just lateral to the umbilical scar. Patients usually present later in life.
Epigastric:	It occurs in the midline between the xiphoid process and the umbilicus. They are usually small (<2 cm). They result when a knuckle of extraperitoneal fat extrudes through a small defect in the linea alba. Commonly irreducible and without an expansile cough impulse.
Spigelian:	A rare hernia found along the linea semilunaris at the lateral edge of the rectus sheath, most commonly a third of the way between the umbilicus and the pubis.

DIVARICATION OF THE RECTI

Supraumbilical elliptical swelling of the attenuated linea alba (no cough impulse).

ABORTION, RECURRENT

ICD-10CM # P01.8 Newborn (suspected to be) affected by other maternal complications of pregnancy

Congenital anatomic abnormalities.
Adhesions (uterine synechiae).
Uterine fibroids.
Endometriosis.
Endocrine abnormalities (luteal phase insufficiency, hypothyroidism, uncontrolled diabetes mellitus [DM]).
Parenteral chromosome abnormalities.
Maternal infections (cervical mycoplasma, ureaplasma, chlamydia).
DES exposure, heavy metal exposure.
Thrombocytosis.
Allogenic immunity, autoimmunity, lupus anticoagulant.

ACALCULOUS GALLBLADDER DISEASE[19]

ICD-10CM # K82.9 Other diseases of gallbladder

Biliary tract anomaly (e.g., choledochal cyst).
Bone marrow transplant.
Burns.
Chemotherapy in oncology patients.
Critical illness in intensive care unit patients.
Crohn disease, Henoch-Schönlein purpura, Kawasaki disease, systemic lupus erythematosus.
Infectious agents (atypical microbes).
Microlithiasis.
Postoperative state (e.g., cardiac surgery).
Sepsis.
Sludge.
Systemic inflammatory states.
Total parenteral nutrition.
Traumatic spinal cord injury.

ACHES AND PAINS, DIFFUSE[50]

ICD-10CM # M25.50 Pain in unspecified joint

Postviral arthralgias/myalgias.
Bilateral soft tissue rheumatism.
Overuse syndromes.
Fibrositis.
Hypothyroidism.
Metabolic bone disease.
Paraneoplastic syndrome.
Myopathy (polymyositis, dermatomyositis).
Rheumatoid arthritis (RA).
Sjögren syndrome.
Polymyalgia rheumatica.
Hypermobility.
Benign arthralgias/myalgias.
Chronic fatigue syndrome.
Hypophosphatemia.

ACIDOSIS, HYPERCHLORIC METABOLIC[88]

ICD-10CM # E87.2 Acidosis

GASTROINTESTINAL BICARBONATE LOSS

Diarrhea.
External pancreatic or small bowel drainage.
Ureterosigmoidostomy, jejunal loop.
Drugs:
- Calcium chloride (acidifying agent).
- Magnesium sulfate (diarrhea).
- Cholestyramine (bile acid diarrhea).

RENAL ACIDOSIS

Hypokalemic:
- Proximal RTA (type 2).
- Distal (classic) RTA (type 1).
- Drug-induced hypokalemia:
  - Acetazolamide (proximal RTA).
  - Amphotericin B (distal RTA).

Hyperkalemic:
- Generalized distal nephron dysfunction (type 4 RTA).
- Mineralocorticoid deficiency or resistance (pseudohypoaldosteronism type 1) PHA-I, PHA-II.
- ↓ Na^+ delivery to distal nephron.
- Tubulointerstitial disease.
- Ammonium excretion defect.
- Drug-induced hyperkalemia:
  - Potassium-sparing diuretics (amiloride, triamterene, spironolactone).
  - Trimethoprim.
  - Pentamidine.
  - Angiotensin-converting enzyme inhibitors and angiotensin II receptor blockers.
  - Nonsteroidal antiinflammatory drugs.
  - Cyclosporine, tacrolimus.

Normokalemic:
- Early renal insufficiency.

OTHER

Acid loads (ammonium chloride, hyperalimentation).
Loss of potential bicarbonate: ketosis with ketone excretion.
Dilution acidosis (rapid saline administration).
Hippurate.
Cation-exchange resins.

ACIDOSIS, LACTIC[88]

ICD-10CM # E87.2 Acidosis

CAUSES OF LACTIC ACIDOSIS

L-Lactic Acidosis

Conditions associated with type A lactic acidosis:
- Poor tissue perfusion.
- Shock:
  - Cardiogenic.
  - Hemorrhagic.
  - Septic.

Profound hypoxemia:
- Severe asthma.
- Carbon monoxide poisoning.

Conditions associated with type B lactic acidosis:
- Liver disease.
- Metformin.
- Inborn errors of metabolism.
- Pyroglutamic acidosis.
- Kombucha tea.

d-Lactic Acidosis

Short bowel syndrome.
Ischemic bowel.
Small bowel obstruction.

ACIDOSIS, METABOLIC

ICD-10CM # E87.2 Acidosis

METABOLIC ACIDOSIS WITH INCREASED ANION GAP (AG ACIDOSIS)

Lactic acidosis.
Ketoacidosis (DM, alcoholic ketoacidosis).
Uremia (chronic renal failure).
Ingestion of toxins (paraldehyde, methanol, salicylate, ethylene glycol).
High-fat diet (mild acidosis).

METABOLIC ACIDOSIS WITH NORMAL AG (HYPERCHLOREMIC ACIDOSIS)

Renal tubular acidosis (including acidosis of aldosterone deficiency).
Intestinal loss of HCO_3^- (diarrhea, pancreatic fistula).
Carbonic anhydrase inhibitors (e.g., acetazolamide).
Dilutional acidosis (as a result of rapid infusion of bicarbonate-free isotonic saline).
Ingestion of exogenous acids (ammonium chloride, methionine, cystine, calcium chloride).
Ileostomy.
Ureterosigmoidostomy.
Drugs: amiloride, triamterene, spironolactone, β-blockers.

ACIDOSIS, RESPIRATORY

ICD-10CM # E87.2 Acidosis

Pulmonary disease (COPD, severe pneumonia, pulmonary edema, interstitial fibrosis).
Airway obstruction (foreign body, severe bronchospasm, laryngospasm).
Thoracic cage disorders (pneumothorax, flail chest, kyphoscoliosis).
Defects in muscles of respiration (myasthenia gravis, hypokalemia, muscular dystrophy).
Defects in peripheral nervous system (amyotrophic lateral sclerosis, poliomyelitis, Guillain-Barré syndrome, botulism, tetanus, organophosphate poisoning, spinal cord injury).
Depression of respiratory center (anesthesia, narcotics, sedatives, vertebral artery embolism or thrombosis, increased intracranial pressure).
Failure of mechanical ventilator.

ACUTE KIDNEY INJURY AND LIVER DISEASE, CAUSES[27,28]

ICD-10CM # S37.009A Unspecified injury of unspecified kidney, initial encounter
K76.89 Other specified diseases of liver

Prerenal uremia:	Diuretic use, GI loss, peritoneal aspiration, hypoalbuminemia.
Hepatorenal syndrome	
Acute tubular necrosis:	Hyperbilirubinemia, sepsis, toxic shock syndrome.
Drugs:	Acetaminophen (paracetamol), NSAIDs, tetracycline, rifampicin, isoniazid, anesthetic agents, sulfonamides, allopurinol, methotrexate.
Infections:	Hepatitis C and cryoglobulinemia, hepatitis B and polyarteritis nodosa, leptospirosis, hantavirus, Epstein-Barr virus, gram-negative sepsis, spontaneous bacterial peritonitis.
Other:	Papillary necrosis and obstruction, inhalation of chlorinated hydrocarbons, mushroom poisoning *(Amanita phalloides).*

ACUTE KIDNEY INJURY DUE TO INTRINSIC RENAL DISEASES[60]

ICD-10CM # Varies with specific diagnosis

INTRINSIC RENAL DISEASES THAT CAUSE ACUTE KIDNEY INJURY

Vascular Diseases
Large-Vessel Diseases
Renal artery thrombosis or stenosis.
Renal vein thrombosis.
Atheroembolic disease.
Small- and Medium-Vessel Diseases
Scleroderma.
Malignant hypertension.
Hemolytic uremic syndrome.
Thrombotic thrombocytopenic purpura.
HIV-associated microangiopathy.
Glomerular Diseases
Systemic Diseases
Systemic lupus erythematosus.
Infective endocarditis.
Systemic vasculitis (e.g., periarteritis nodosa, granulomatosis with polyangiitis).
Henoch-Schönlein purpura.
HIV-associated nephropathy.
Essential mixed cryoglobulinemia.
Goodpasture syndrome.
Primary Renal Diseases
Poststreptococcal glomerulonephritis.
Other postinfectious glomerulonephritis.
Rapidly progressive glomerulonephritis.
Tubulointerstitial Diseases and Conditions
Drugs (many).
Toxins (e.g., heavy metals, ethylene glycol).
Infections.
Multiple myeloma.
Acute Tubular Necrosis
Ischemia
Shock.
Sepsis.
Severe prerenal azotemia.
Nephrotoxins
Antibiotics.
Radiographic contrast agents.
Myoglobinuria.
Hemoglobinuria.
Other Diseases and Conditions
Severe liver disease.
Allergic reactions.
NSAIDs.

ACUTE KIDNEY INJURY, HIV PATIENT, CAUSES[27,28]

ICD-10CM # S37.009A Unspecified injury of unspecified kidney, initial encounter with B20 human immunodeficiency virus (HIV) disease

Prerenal:	Diarrhea, nausea and vomiting, cirrhosis and hepatorenal syndrome, sepsis.
Vascular:	Thrombotic microangiopathy.
Glomerular:	Immune complex glomerulonephritis (MPGN secondary to hepatitis C virus, postinfectious glomerulonephritis), HIVAN.
Acute tubular necrosis:	Sepsis, hypotension, nephrotoxins (aminoglycosides, amphotericin, acyclovir, cidofovir, tenofovir, pentamidine).
Acute interstitial nephritis:	Drug-induced (co-trimoxazole), rifampicin, foscarnet, nevirapine), CMV infection, DILS.
Drug-induced intratubular obstruction:	Sulfadiazine, indinavir, foscarnet, acyclovir.
Postrenal obstruction:	Stones, tuberculosis, fungal ball, tumor.
Associated with IV drug use:	Sepsis, endocarditis, heroin-associated nephropathy (FSGS), rhabdomyolysis.

CMV, Cytomegalovirus; *DILS,* diffusive infiltrative lymphocytosis syndrome; *FSGS,* focal segmental glomerulosclerosis; *HIVAN,* HIV-associated nephropathy; *MPGN,* membranoproliferative glomerulonephritis.

ACUTE KIDNEY INJURY IN SPECIFIC CLINICAL SETTINGS[79]

ICD-10CM # N17.9 Acute kidney failure, unspecified

MAJOR CAUSES OF ACUTE KIDNEY INJURY IN SPECIFIC CLINICAL SETTINGS

AKI in the Cancer Patient
Prerenal azotemia:
- Hypovolemia (e.g., poor intake, vomiting, diarrhea).

Intrinsic AKI:
- Exogenous nephrotoxins: chemotherapy, antibiotics, contrast media.
- Endogenous toxins: hyperuricemia, hypercalcemia, tumor lysis, paraproteins.
- Other: radiation, HUS/TTP, glomerulonephritis, amyloid, malignant infiltration.

Postrenal AKI:
- Ureteric or bladder neck obstruction.

AKI after Cardiac Surgery
Prerenal azotemia:
- Hypovolemia (surgical losses, diuretics), cardiac failure, vasodilators.

Intrinsic AKI:
- Ischemic ATN (even in absence of hypotension).
- Atheroembolic disease after aortic manipulation/intraaortic balloon pump.
- Preoperative or perioperative administration of contrast medium.
- Allergic interstitial nephritis induced by perioperative antibiotics.

Postrenal AKI:
- Obstructed urinary catheter, exacerbation of voiding dysfunction.

AKI in Pregnancy

Prerenal azotemia:
- Acute fatty liver of pregnancy with fulminant hepatic failure.

Intrinsic AKI:
- Preeclampsia or eclampsia.
- Postpartum HUS/TTP.
- HELLP syndrome.
- Ischemia: postpartum hemorrhage, abruptio placentae, amniotic fluid embolus.
- Direct toxicity of illegal abortifacients.

Postrenal AKI:
- Obstruction with pyelonephritis.

AKI after Solid Organ or Bone Marrow Transplantation

Prerenal azotemia:
- Intravascular volume depletion (e.g., diuretic therapy).
- Vasoactive drugs (e.g., calcineurin inhibitors, amphotericin B).
- Hepatorenal syndrome, venoocclusive disease of liver (BMT).

Intrinsic AKI:
- Postoperative ischemic ATN (even in absence of hypotension).
- Sepsis.
- Exogenous nephrotoxins: aminoglycosides, amphotericin B, radiocontrast media.
- HUS/TTP (e.g., cyclosporine or myeloablative radiotherapy related).
- Allergic tubulointerstitial nephritis.

Postrenal AKI:
- Obstructed urinary catheter.

AKI and Pulmonary Disease (Pulmonary Renal Syndrome)

Prerenal azotemia:
- Diminished cardiac output complicating pulmonary embolism, severe pulmonary hypertension, or positive-pressure mechanical ventilation.

Intrinsic AKI:
- Vasculitis.
  - Goodpasture syndrome, ANCA-associated vasculitis, SLE, eosinophilic granulomatosis with polyangiitis, polyarteritis nodosa, cryoglobulinemia, right-sided endocarditis, lymphomatoid granulomatosis, sarcoidosis, scleroderma.

Toxins:
- Ingestion of paraquat or diquat.

Infections:
- Legionnaires disease, *Mycoplasma* infection, tuberculosis, disseminated viral or fungal infection.
- AKI from any cause with hypervolemia and pulmonary edema.
- Lung cancer with hypercalcemia, tumor lysis, or glomerulonephritis.

AKI and Liver Disease

Prerenal azotemia:
- Reduced true (GI hemorrhage, GI losses from lactulose, diuretics, large-volume paracentesis) circulatory volume or effective (hypoalbuminemia, splanchnic vasodilation).
- Hepatorenal syndrome type 1 or 2.
- Tense ascites with abdominal compartment syndrome.

Intrinsic AKI:
- Ischemic (severe hypoperfusion—see earlier) or direct nephrotoxicity and hepatotoxicity of drugs or toxins (e.g., carbon tetrachloride, acetaminophen, tetracyclines, methoxyflurane).
- Tubulointerstitial nephritis plus hepatitis caused by drugs (e.g., sulfonamides, rifampin, phenytoin, allopurinol, phenindione), infections (leptospirosis, brucellosis, Epstein-Barr virus infection, cytomegalovirus infection), malignant infiltration (leukemia, lymphoma), or sarcoidosis.
- Glomerulonephritis or vasculitis (e.g., polyarteritis nodosa, ANCA-associated glomerulonephritis, cryoglobulinemia, SLE, postinfectious hepatitis or liver abscess.

AKI and Nephrotic Syndrome

Prerenal azotemia:
- Intravascular volume depletion (diuretic therapy, hypoalbuminemia).

Intrinsic AKI:
- Manifestation of primary glomerular disease.
- Collapsing glomerulopathy (e.g., HIV, pamidronate).
- Associated ATN (older hypertensive males).
- Associated interstitial nephritis (NSAIDs, rifampin, interferon alfa).

Other: amyloid or light-chain deposition disease, renal vein thrombosis, severe interstitial edema.

AKI, Acute kidney injury; *ANCA,* antineutrophil cytoplasmic antibody; *ATN,* acute tubular necrosis; *BMT,* bone marrow transplantation; *GI,* gastrointestinal; *HELLP, h*emolysis, *e*levated *l*iver enzymes, *l*ow *p*latelets; *HIV,* human immunodeficiency virus; *HUS,* hemolytic uremic syndrome; *NSAID,* nonsteroidal antiinflammatory drug; *SLE,* systemic lupus erythematosus; *TTP,* thrombotic thrombocytopenic purpura.

ACUTE KIDNEY INJURY, PIGMENT INDUCED[60]

ICD-10CM # Varies with specific diagnosis

CAUSES OF PIGMENT-INDUCED ACUTE KIDNEY INJURY

Rhabdomyolysis and myoglobinuria.
- Vigorous exercise.
- Arterial embolization.
- Status epilepticus.
- Status asthmaticus.
- Coma-induced and pressure-induced myonecrosis.
- Heat stress.
- Diabetic ketoacidosis.
- Myopathy.
- Alcoholism.
- Hypokalemia.
- Hypophosphatemia.

Hemoglobinuria.
- Transfusion reactions.
- Snake envenomation.
- Malaria.
- Mechanical destruction of RBCs by prosthetic valves.
- G6PD deficiency.

G6PD, Glucose-6-phosphate dehydrogenase.

ACUTE LUNG INJURY, DISEASE AND DISORDER ASSOCIATIONS[61]

ICD-10CM # S27.3 Injury, lung

CLINICAL DISORDERS ASSOCIATED WITH ACUTE LUNG INJURY

Infectious Causes

Gram-negative or gram-positive sepsis.
- Bacterial pneumonia.
- Viral pneumonia.
- Fungal pneumonia
- Parasitic infections.
- Mycobacterial disease.

Aspiration

Gastric acid.
- Food and other particulate matter.
- Fresh or sea water (near drowning).
- Hydrocarbon fluids.

Trauma

Lung contusion.
- Fat emboli.
- Nonthoracic trauma.
- Thermal injury (burns).
- Blast injury (explosion, lightning).
- Overdistention (mechanical ventilation).
- Inhaled gases (phosgene, ammonia).

Hemodynamic Disturbances

Shock of any etiology.
- Anaphylaxis.
- High-altitude pulmonary edema.
- Reperfusion.
- Air embolism.
- Amniotic fluid embolism.

Drugs

Heroin.
- Methadone.
- Propoxyphene.
- Naloxone.
- Cocaine.
- Barbiturates.
- Colchicine.
- Salicylates.
- Ethchlorvynol.
- Interleukin-2.
- Protamine.
- Hydrochlorothiazide.

Hematologic Disorders

Disseminated intravascular coagulation.
- Incompatible blood transfusion.
- Rh incompatibility.
- Antileukocyte antibodies.
- Leucoagglutinin reactions.
- Post–cardiopulmonary bypass, pump oxygenator.

Metabolic Disorders

Pancreatitis.
- Diabetic ketoacidosis.

Neurologic Disorders
Head trauma.
Grand mal seizures.
Increased intracranial pressure (any cause).
Subarachnoid or intracerebral hemorrhage.
Miscellaneous Disorders
Lung reexpansion.
Upper airway obstruction.

ACUTE RESPIRATORY DISTRESS IN PREGNANCY[70]

ICD-10CM # J96.00 Acute respiratory failure

Disorder	Distinguishing Features
Pregnancy-Specific	
Amniotic fluid embolism.	Cardiorespiratory collapse, seizures, DIC.
Pulmonary edema secondary to preeclampsia.	Hypertension, proteinuria.
ARDS secondary to obstetric sepsis.	Evidence of obstetric sepsis, shock.
Tocolytic pulmonary edema.	Tocolytic administration, rapid improvement.
Peripartum cardiomyopathy.	Gradual onset, cardiac gallop, cardiomegaly.
Trophoblastic embolism.	Nodular infiltrate, molar pregnancy.
Risk Increased by Pregnancy	
Aspiration pneumonitis.	Vomiting, aspiration.
Venous thromboembolism.	Evidence of DVT, positive V̇/Q̇ scan, leg Doppler, CT angiogram.
Pneumomediastinum.	Occurs during delivery, subcutaneous emphysema.
Valvular heart disease.	Pulmonary edema, cardiac murmur, cardiomegaly.
ARDS secondary to sepsis.	Evidence of sepsis (e.g., pyelonephritis).
Unrelated to Pregnancy	
Asthma.	Features similar to nonpregnant patient.
Pneumonia.	Features similar to nonpregnant patient.

ARDS, Acute respiratory distress syndrome; *CT,* computed tomography; *DIC,* disseminated intravascular coagulopathy; *DVT,* deep venous thrombosis; V̇/Q̇, ventilation-perfusion.

ACUTE SCROTUM

ICD-10CM # R10.2 Pelvic and perineal pain

Testicular torsion.
Epididymitis.
Testicular neoplasm.
Orchitis.
Trauma.

ADNEXAL MASS[58]

ICD-10CM # R19.00 Intraabdominal and pelvic swelling, mass and lump, unspecified site

Ovary (neoplasm, endometriosis, functional cyst).
Fallopian tube (ectopic pregnancy, neoplasm, tuboovarian abscess, hydrosalpinx, paratubal cyst).
Uterus (fibroid, neoplasm).
Retroperitoneum (neoplasm, abdominal wall hematoma or abscess).
Urinary tract (pelvic kidney, distended bladder, urachal cyst).
Inflammatory bowel disease.
GI tract neoplasm.
Diverticular disease.
Appendicitis.
Bowel loop with feces.

ADRENAL CALCIFICATIONS[74]

ICD-10CM # E27.8 Other specified disorder of adrenal gland

CAUSES OF ADRENAL CALCIFICATION

Infection:
- Tuberculosis.
- Histoplasmosis.
- *Echinococcus.*

Prior hemorrhage.
Neoplasm:
- Adrenocortical carcinoma.
- Myelolipoma.
- Pheochromocytoma.

Hemangioma (rare).

ADRENAL CYSTIC LESIONS[74]

ICD-10CM # E27.8 Other specified disorder of adrenal gland

CYSTIC ADRENAL LESIONS

Pseudocyst.
Endothelial cyst.
Epithelial cyst.
Infection (*Echinococcus,* abscess).
Necrotic neoplasm.
Cystic pheochromocytoma.
Lymphangioma.

ADRENAL INSUFFICIENCY, CRITICALLY ILL PATIENT[73]

ICD-10CM # E27.40 Unspecified adrenocortical insufficiency

CAUSES OF ADRENAL INSUFFICIENCY IN CRITICALLY ILL PATIENTS

Reversible Dysfunction of the HPA Axis
Sepsis/septic shock.
Acute lung injury.
Burns.
Pancreatitis.
Liver failure.
Hypothermia.
Drugs:
- Etomidate (primary AI).
- Corticosteroids (secondary AI).
- Ketoconazole (primary AI).
- Megestrol acetate (secondary AI).
- Rifampin (increased cortisol metabolism).
- Phenytoin (increased cortisol metabolism).
- Metyrapone (primary AI).
- Mitotane (primary AI).

Primary Adrenal Insufficiency (Adrenal Failure)
Autoimmune adrenalitis.
HIV infection:
- HART therapy.
- HIV virus.
- CMV.

Metastatic carcinoma:
- Lung.
- Breast.
- Kidney.

Systemic fungal infection:
- Histoplasmosis.
- Cryptococcus.
- Blastomycosis.

Tuberculosis.
Adrenal hemorrhage/infarction:
- DIC.
- Meningococcemia.
- Anticoagulation.
- Antiphospholipid syndrome.
- HIT.
- Trauma.

AI, Adrenal insufficiency; *CMV,* cytomegalovirus; *DIC,* disseminated intravascular coagulation; *HIT,* heparin-induced thrombocytopenia; *HPA,* hypothalamic-pituitary axis.

ADRENAL MASSES[82]

ICD-10CM # C74.90 Malignant neoplasm of unspecified part of unspecified adrenal gland
E27.8 Other specified disorders of adrenal gland

UNILATERAL ADRENAL MASSES

Functional Lesions
Adrenal adenoma.
Adrenal carcinoma.
Pheochromocytoma.
Primary aldosteronism, adenomatous type.
Nonfunctional Lesions
Incidentaloma of adrenal.
Ganglioneuroma.
Myelolipoma.
Hematoma.
Adenolipoma.
Metastasis.

BILATERAL ADRENAL MASSES

Functional Lesions
ACTH-dependent Cushing syndrome.
Congenital adrenal hyperplasia.
Pheochromocytoma.
Conn syndrome, hyperplastic variety.
Micronodular adrenal disease.
Idiopathic bilateral adrenal hypertrophy.
Nonfunctional Lesions
Infection (tuberculosis, fungi).
Infiltration (leukemia, lymphoma).
Replacement (amyloidosis).
Hemorrhage.
Bilateral metastases.

ADRENAL PSEUDOMASSES[74]

ICD-10CM # E27.8 Other specified disorder of adrenal gland

Thickened diaphragmatic crus.
Accessory spleen.
Gastric fundus.
Gastric diverticulum.
Renal vein.
Retrocrural and retroperitoneal adenopathy.
Upper-pole renal cysts and tumors.
Pancreatic tumors.
Hypertrophied caudate lobe of liver.
Fluid-filled colon interposed between stomach and kidney.

ADRENERGIC TOXIDROME[73]

ICD-10CM # T44.8X1S Poisoning by centrally acting and adrenergic-neuron-blocking agents, accidental (unintentional), sequela

COMMON CAUSES OF THE ADRENERGIC TOXIDROME

Recreational drugs:
Cocaine.
Amphetamines and other "designer drugs"[a]; "ecstasy" (3,4-methylenedioxymethamphetamine [MDMA]); 3,4-methylenedioxyamphetamine (MDA); 3,4-methylenedioxyethylamphetamine (MDEA); paramethoxyamphetamine (PMA); methamphetamine.
β_1-Adrenergic agents:
Salbutamol.
Theophylline.
Inotropic agents:
Norepinephrine.
Epinephrine.
Isoproterenol.
Over-the-counter cough and cold preparations and nasal decongestants:
Phenylpropanolamine.
Pseudoephedrine.
Amphetamine-like agents prescribed for ADD or weight loss:
Methylphenidate.
Dextroamphetamine.
Psychostimulants.

ADD, Attention deficit disorder.

[a]Up to 80% of ecstasy tablets sold in Australia are actually methamphetamine.

ADRENOCORTICAL HYPERFUNCTION[3]

ICD-10CM # E26.9 Hyperaldosteronism, unspecified

SYNDROMES OF ADRENOCORTICAL HYPERFUNCTION

States of Glucocorticoid Excess
Physiologic States
Stress.
Strenuous exercise.
Last trimester of pregnancy.
Pathologic States
Psychiatric conditions (pseudo-Cushing disorders):
Depression.
Alcoholism.
Anorexia nervosa.
Panic disorders.
Alcohol and drug withdrawal.
ACTH-dependent states:
Pituitary adenoma (Cushing disease).
Ectopic ACTH syndrome.
Bronchial carcinoid.
Thymic carcinoid.
Islet cell tumor.
Small cell lung carcinoma.
Ectopic CRH secretion.
ACTH-independent states:
Adrenal adenoma.
Adrenal carcinoma.
Micronodular adrenal disease.
Exogenous Sources
Glucocorticoid intake.
ACTH intake.
States of Mineralocorticoid Excess
Primary Aldosteronism
Aldosterone-secreting adenoma.
Bilateral adrenal hyperplasia.
Aldosterone-secreting carcinoma.
Glucocorticoid-suppressible hyperaldosteronism.
Adrenal Enzyme Deficiencies
11b-Hydroxylase deficiency.
17a-Hydroxylase deficiency.
11b-Hydroxysteroid dehydrogenase, type II.
Exogenous Mineralocorticoids
Licorice.
Carbenoxolone.
Fludrocortisone.
Secondary Hyperaldosteronism
Associated with hypertension:
Accelerated hypertension.
Renovascular hypertension.
Estrogen administration.
Renin-secreting tumors.
Without hypertension:
Bartter syndrome.
Sodium-wasting nephropathy.
Renal tubular acidosis.
Diuretic and laxative abuse.
Edematous states (cirrhosis, nephrosis, congestive heart failure).

ACTH, Adrenocorticotropin hormone; *CRH,* corticotropin-releasing hormone.

ADRENOCORTICAL HYPOFUNCTION

ICD-10CM # E27.49 Other adrenocortical insufficiency

SYNDROMES OF ADRENOCORTICAL HYPOFUNCTION

Primary Adrenal Disorders
Combined Glucocorticoid and Mineralocorticoid Deficiency
Autoimmune:
Isolated autoimmune disease (Addison disease).
Polyglandular autoimmune syndrome, type I.
Polyglandular autoimmune syndrome, type II.
Infectious:
Tuberculosis.
Fungal.
Cytomegalovirus.
Human immunodeficiency virus.
Vascular:
Bilateral adrenal hemorrhage.
Sepsis.
Coagulopathy.
Thrombosis; embolism.
Adrenal infarction.
Infiltration:
Metastatic carcinoma and lymphoma.
Sarcoidosis.
Amyloidosis.
Hemochromatosis.
Congenital:
Congenital adrenal hyperplasia.
21-Hydroxylase deficiency.
3b-o1 Dehydrogenase deficiency.
20,22-Desmolase deficiency.
Adrenal unresponsiveness to ACTH.
Congenital adrenal hypoplasia.
Adrenoleukodystrophy.
Adrenomyeloneuropathy.
Iatrogenic
Bilateral adrenalectomy.
Drugs:
Metyrapone, aminoglutethimide, trilostane, ketoconazole, o,p'-DDD, mifepristone.
Mineralocorticoid deficiency without glucocorticoid deficiency
Corticosterone methyl oxidase deficiency.
Isolated zona glomerulosa defect.
Heparin therapy.
Critical illness.
Converting-enzyme inhibitors.
Secondary Adrenal Disorders
Secondary Adrenal Insufficiency
Hypothalamic-pituitary dysfunction.
Exogenous glucocorticoids.
After removal of an ACTH-secreting tumor.
Hyporeninemic Hypoaldosteronism
Diabetic nephropathy.
Tubulointerstitial diseases.
Obstructive uropathy.
Autonomic neuropathy.
Nonsteroidal antiinflammatory drugs.
β-Adrenergic drugs.

ACTH, Adrenocorticotropic hormone.

ADVERSE FOOD REACTIONS, DIFFERENTIAL DIAGNOSIS[53]

ICD-10CM # T78.1XXA Other adverse food reactions, not elsewhere classified, initial encounter

GASTROINTESTINAL DISORDERS (WITH VOMITING AND/OR DIARRHEA)

Structural abnormalities (pyloric stenosis, Hirschsprung disease).
Enzyme deficiencies (primary or secondary):

Disaccharidase deficiency: lactase, fructose, sucrase-isomaltase.
Galactosemia.
Other: pancreatic insufficiency (cystic fibrosis), peptic disease.

CONTAMINANTS AND ADDITIVES

Flavorings and preservatives—rarely cause symptoms: sodium metabisulfite, monosodium glutamate, nitrites.
Dyes and colorings—very rarely cause symptoms (urticaria, eczema): tartrazine.
Toxins: bacterial, fungal (aflatoxin), fish-related (scombroid, ciguatera).
Infectious organisms:
Bacteria *(Salmonella, Escherichia coli, Shigella)*.
Virus (rotavirus, enterovirus).
Parasites (*Giardia*, Akis simplex [in fish]).
Accidental contaminants: heavy metals, pesticides.
Pharmacologic agents: caffeine, glycosidal alkaloid solanine (potato spuds), histamine (fish), serotonin (banana, tomato), tryptamine (tomato), tyramine (cheese).

PSYCHOLOGIC REACTIONS

Food phobias.

ADYNAMIC ILEUS[58]

ICD-10CM #		
	K56.0	Paralytic ileus
	K56.7	Ileus, unspecified

Abdominal trauma.
Infection (retroperitoneal, pelvic, intrathoracic).
Laparotomy.
Metabolic disease (hypokalemia).
Renal colic.
Skeletal injury (rib fracture, vertebral fracture).
Medications (e.g., narcotics).

AEROPHAGIA (BELCHING, ERUCTATION)

ICD-10CM #		
	R14.0	Abdominal distention (gaseous)
	R14.1	Gas pain
	R14.2	Eructation
	R14.3	Flatulence

Anxiety disorders.
Rapid food ingestion.
Carbonated beverages.
Nursing infants (especially when nursing in horizontal position).
Eating or drinking in supine position.
Gum chewing.
Poorly fitting dentures, orthodontic appliances.
Hiatal hernia, gastritis, nonnuclear dyspepsia.
Cholelithiasis, cholecystitis.
Ingestion of legumes, onions, peppers.

AIR-SPACE OPACIFICATION ON X-RAY[36]

ICD-10CM #		
	R91.8	Other nonspecific abnormal finding of lung field

CAUSES OF AIR-SPACE OPACIFICATION

Edema
Cardiogenic.
Non-cardiogenic.
Inflammation/Infection
Granulomatosis with polyangiitis.
Cryptogenic organizing pneumonia.
Blood
Idiopathic pulmonary hemosiderosis.
Antibasement membrane antibody disease.
Systemic lupus erythematosus.
Miscellaneous Causes
Eosinophilic pneumonia.
Alveolar proteinosis.
Alveolar cell carcinoma.
Alveolar microlithiasis.
Lymphoma (MALToma).
Sarcoidosis.

AIRWAY OBSTRUCTION, PEDIATRIC AGE[43]

ICD-10CM #		
	J44.9	Chronic obstructive pulmonary disease, unspecified
	T17.900A	Unspecified foreign body in respiratory tract, part unspecified causing asphyxiation, initial encounter
	T17.908A	Unspecified foreign body in respiratory tract, part unspecified causing other injury, initial encounter
	T17.910A	Gastric contents in respiratory tract, part unspecified causing asphyxiation, initial encounter
	T17.918A	Gastric contents in respiratory tract, part unspecified causing other injury, initial encounter
	T17.920A	Food in respiratory tract, part unspecified causing asphyxiation, initial encounter
	T17.928A	Food in respiratory tract, part unspecified causing other injury, initial encounter
	T17.990A	Other foreign object in respiratory tract, part unspecified in causing asphyxiation, initial encounter
	T17.998A	Other foreign object in respiratory tract, part unspecified causing other injury, initial encounter
	J38.5	Laryngeal spasm
	J68.9	Unspecified respiratory condition due to chemicals, gases, fumes, and vapors

CONGENITAL CAUSES

Craniofacial dysmorphism.
Hemangioma.
Laryngeal cleft/web.
Laryngoceles, cysts.
Laryngomalacia.
Macroglossia.
Tracheal stenosis.
Vascular ring.
Vocal cord paralysis.

ACQUIRED INFECTIOUS CAUSES

Acute laryngotracheobronchitis.
Epiglottitis.
Laryngeal papillomatosis.
Membranous croup (bacterial tracheitis).
Mononucleosis.
Retropharyngeal abscess.
Spasmodic croup.
Diphtheria.

ACQUIRED NONINFECTIOUS CAUSES

Anaphylaxis.
Foreign body aspiration.
Supraglottic hypotonia.
Thermal/chemical burn.
Trauma.
Vocal cord paralysis.
Angioneurotic edema.

AKINETIC/RIGID SYNDROME[3]

ICD-10CM #		
	R29.8	Akinesis

Parkinsonism (idiopathic, drug-induced).
Catatonia (psychosis).
Progressive supranuclear palsy.
Multisystem atrophy (Shy-Drager syndrome, olivopontocerebellar atrophy).
Diffuse Lewy-body disease.
Toxins (MPTP, manganese, carbon monoxide).
Huntington disease and other hereditary neurodegenerative disorders.

ALCOHOL-RELATED SEIZURES[60]

ICD-10CM #	
F10.232	Alcohol dependence with withdrawal with perceptual disturbance

DIFFERENTIAL DIAGNOSIS OF ALCOHOL-RELATED SEIZURES

Withdrawal (alcohol or drugs).
Exacerbation of idiopathic or posttraumatic seizures.
Acute intoxication (amphetamines, anticholinergics, cocaine, isoniazid, organophosphates, phenothiazines, tricyclic antidepressants, salicylates, lithium).
Metabolic (hypoglycemia, hyponatremia, hypernatremia, hypocalcemia, hepatic failure).

Infectious (meningitis, encephalitis, brain abscess).
Trauma (intracranial hemorrhage).
Cerebrovascular accident.
Sleep deprivation.
Noncompliance with anticonvulsants.

ALKALOSIS, METABOLIC

ICD-10CM # E87.3 Alkalosis

CAUSES OF METABOLIC ALKALOSIS

Exogenous HCO_3– loads.
Acute alkali administration.
Milk-alkali syndrome.
Effective Extracellular Volume Contraction, Normotension, Hypokalemia, and Secondary Hyperreninemic Hyperaldosteronism
GI origin:
- Vomiting.
- Gastric aspiration.
- Congenital chloridorrhea.
- Villous adenoma.
- Combined administration of sodium polystyrene sulfonate (Kayexalate and aluminum hydroxide).

Renal origin:
- Diuretics (especially thiazides and loop diuretics).
- Acute.
- Chronic.
- Edematous states.
- Posthypercapnic state.
- Hypercalcemia-hypoparathyroidism.
- Recovery from lactic acidosis or ketoacidosis.
- Nonreabsorbable anions such as penicillin, carbenicillin.
- Mg++ deficiency.
- K+ depletion.
- Bartter syndrome (loss-of-function mutation of Cl– transport in thick ascending limb of Henle loop).
- Gitelman syndrome (loss-of-function mutation in Na+/Cl– cotransporter).
- Carbohydrate refeeding after starvation.

Extracellular Volume Expansion, Hypertension, K^+ Deficiency, and Hypermineralocorticoidism
Associated with high renin:
- Renal artery stenosis.
- Accelerated hypertension.
- Renin-secreting tumor.
- Estrogen therapy.

Associated with low renin:
- Primary aldosteronism.
- Adenoma.
- Hyperplasia.
- Carcinoma.
- Glucocorrticoid suppressible.

Adrenal enzymatic defects:
- 11β-Hydroxylase deficiency.
- 17α-Hydroxylase deficiency.

Cushing syndrome or disease:
- Ectopic corticotropin.
- Adrenal carcinoma.
- Adrenal adenoma.
- Primary pituitary.

Other:
- Licorice.
- Carbenoxolone.
- Chewer's tobacco.
- Lydia Pinkham tablets.

Gain-of-Function Mutation of ENaC with Extracellular Fluid Volume Expansion, Hypertension, K^+ Deficiency, and Hyporeninemic Hypoaldosteronism
Liddle syndrome.

ALKALOSIS, RESPIRATORY

ICD-10CM # E87.3 Alkalosis

Hypoxemia (pneumonia, pulmonary embolism, atelectasis, high-altitude living).
Drugs (salicylates, xanthenes, progesterone, epinephrine, thyroxine, nicotine).
Central nervous system (CNS) disorders (tumor, cerebrovascular accident [CVA], trauma, infections).
Psychogenic hyperventilation (anxiety, hysteria).
Hepatic encephalopathy.
Gram-negative sepsis.
Hyponatremia.
Sudden recovery from metabolic acidosis.
Assisted ventilation.

ALOPECIA[32,61]

ICD-10CM #		
	L65.9	Nonscarring hair loss, unspecified
	L63.2	Ophiasis
	L63.8	Other alopecia areata
	Q84.0	Congenital alopecia
	Q84.1	Congenital morphological disturbances of hair, not elsewhere classified
	Q84.2	Other congenital malformations of hair
	F54	Psychological and behavioral factors associated with disorders or diseases classified elsewhere

SCARRING ALOPECIA

Congenital (aplasia cutis).
Tinea capitis with inflammation (kerion).
Bacterial folliculitis.
Discoid lupus erythematosus.
Lichen planopilaris.
Folliculitis decalvans.
Neoplasm.
Trauma.

NONSCARRING ALOPECIA

Cosmetic treatment.
Tinea capitis.
Structural hair shaft disease.
Trichotillomania (hair pulling).
Anagen arrest.
Telogen arrest.
Alopecia areata.
Androgenetic alopecia.

ALOPECIA AND HYPOTRICHOSIS, IN CHILDREN AND ADOLESCENTS

ICD-10CM #		
	L65.9	Nonscarring hair loss, unspecified
	L63.2	Ophiasis
	L63.8	Other alopecia areata
	Q84.0	Congenital alopecia
	Q84.1	Congenital morphological disturbances of hair, not elsewhere classified
	Q84.2	Other congenital malformations of hair

Congenital total alopecia: atrichia with papules, Moynahan alopecia syndrome.
Congenital localized alopecia: aplasia cutis, triangular alopecia, sebaceous nevus.
Hereditary hypotrichosis: Marie-Unna syndrome, hypotrichosis with juvenile macular dystrophy, hypotrichosis–Mari type, ichthyosis with hypotrichosis, cartilage-hair hypoplasia, Hallermann-Streiff syndrome, trichorhinophalangeal syndrome, ectodermal dysplasia ("pure" hair and nail and other ectodermal dysplasias).
Diffuse alopecia of endocrine origin: hypopituitarism, hypothyroidism, hypoparathyroidism, hyperthyroidism.
Alopecia of nutritional origin: marasmus, kwashiorkor, iron deficiency, zinc deficiency (acrodermatitis enteropathica), gluten-sensitive enteropathy, essential fatty acid deficiency, biotinidase deficiency.
Disturbances of the hair cycle: telogen effluvium.
Toxic alopecia: anagen effluvium.
Autoimmune alopecia: alopecia areata.
Traumatic alopecia: traction alopecia, trichotillomania.
Cicatricial alopecia: lupus erythematosus, lichen planopilaris, pseudopelade, morphea (en coup de saber), dermatomyositis, infection (kerion, favus, tuberculosis, syphilis, folliculitis, leishmaniasis, herpes zoster, varicella), acne keloidalis, follicular mucinosis, sarcoidosis.
Hair shaft abnormalities: monilethrix, pili annulati, pili torti, trichorrhexis invaginata, trichorrhexis nodosa, woolly hair syndrome, Menkes disease, trichothiodystrophy, tricho-dento-osseous syndrome, uncombable hair syndrome (spun-glass hair, pili trianguli et canaliculi).

ALOPECIA, DRUG-INDUCED

ICD-10CM #		
	L65.9	Nonscarring hair loss, unspecified
	L63.8	Alopecia areata

DRUGS REPORTED TO INDUCE HAIR LOSS

ACE inhibitors (captopril, enalapril, moexipril, ramipril).
Allopurinol.
Amiodarone.

Amphetamines.[1,2]
Analgesics, antiinflammatories (ibuprofen, indomethacin, naproxen).
Androgens.[3]
Anticoagulants (coumarin, dextran, heparin/heparinoids).
Antiepileptics (carbamazepine, hydantoins, lamotrigine, troxidone, valproic acid, vigabatrin).
Antipsychotics (flupenthixol decanoate, fluphenazine decanoate).
Antithyroid drugs (carbimazole, iodine, thiouracil).
Appetite suppressants.
Aromatase inhibitors (fadrozole, 4-OHA, vorozole).
Benzimidazoles (albendazole, mebendazole)
β-Blockers (levobunolol, metoprolol, nadolol, propranolol, timolol).
Bromocriptine.
Buspirone.
Butyrophenones.
Cantharidin.
Chloramphenicol.
Cholestyramine.
Cidofovir.
Cimetidine.
Clonazepam.
Clotrimazole.
Colchicine.
Contraceptives (oral).[4]
Danazol.
Diazoxide.
Diclofenac.
Dixyrazine.
Ethambutol.
Ethionamide.
Fibrates (clofibrate, fenofibrate).
G-CSF (granulocyte-colony stimulating factor)
Gefitinib.[5]
Gentamicin.
Glatiramer acetate.
Glibenclamide.
Gold salts.
Haloperidol.
Immunoglobulins.
Indanediones.
Indinavir.
Interferons.
Isonicotinic acid hydrazide.[6]
Leflunomide.
Levodopa.
Lithium.
Maprotiline.
Mesalazine.
Methyldopa.
Methysergide.
Metyrapone.
Minoxidil.
Nicotinic acid.
Nitrofurantoin.
Octreotide.
Olanzapine.
Pentosan polysulfate.
Phenindione.
Potassium thiocyanate.
Pyridostigmine.
Radiation (<700 Gy).
Retinoids (acitretin, etretinate, isotretinoin).
Retinol (vitamin A).
Risperidone.
Salicylates.
Serotonin reuptake inhibitors (fluoxetine, fluvoxamine, paroxetine, sertraline).
Sorafenib.
Spironolactone.
Strontium ranelate.
Sulfasalazine.
Tamoxifen.
Terbinafine.
Terfenadine.
Thiamphenicol.
Thyroxine.
Tocopherol (vitamin E).
Trazodone.
Triazoles (fluconazole, itraconazole).
Tricyclic antidepressants (amitriptyline, desipramine, doxepin, imipramine, maprotiline).
Trimethadione.
Triparanol.
Vasopressin.

[1] Established by multiple reports or proved by rechallenge.
[2] Involvement principally of cancellous bone.
[3] May produce androgenetic alopecia.
[4] May produce telogen effluvium 3 months after discontinuation.
[5] Involvement of cancellous and cortical bone.
[6] May produce anagen effluvium.

[†] Hair loss usually severe.

ALVEOLAR CONSOLIDATION

ICD-10CM #		
	J18.2	Hypostatic pneumonia, unspecified organism
	J81.1	Hypostatic pneumonia, unspecified organism

Infection.
Neoplasm (bronchoalveolar carcinoma, lymphoma).
Aspiration.
Trauma.
Hemorrhage (granulomatosis with polyangiitis, Goodpasture, bleeding diathesis).
ARDS.
CHF.
Renal failure.
Eosinophilic pneumonia.
Bronchiolitis obliterans.
Pulmonary alveolar proteinosis.

ALVEOLAR HEMORRHAGE[65]

ICD-10CM #		
	P26.1	Massive pulmonary hemorrhage originating in the perinatal period
	K08.8	Alveolar hemorrhage
	P26.8	Other pulmonary hemorrhages originating in the perinatal period

Hematologic disorders (coagulopathies, thrombocytopenia).
Goodpasture syndrome (anti-basement membrane antibody disease).
Granulomatosis with polyangiitis.
Immune complex-mediated vasculitis.
Idiopathic pulmonary hemosiderosis.
Drugs (penicillamine).
Lymphangiogram contrast.
Mitral stenosis.

AMENORRHEA

ICD-10CM #		
	N91.2	Amenorrhea, unspecified

PREGNANCY

Early Menopause

Hypothalamic Dysfunction

Defective synthesis or release of LHRH, anorexia nervosa, stress, exercise.

Pituitary Dysfunction

Neoplasm, postpartum hemorrhage, surgery, radiotherapy.

Ovarian Dysfunction

Gonadal dysgenesis, 17a-hydroxylase deficiency, premature ovarian failure, polycystic ovarian disease, gonadal stromal tumors.

UTEROVAGINAL ABNORMALITIES

Congenital: imperforate hymen, imperforate cervix, imperforate or absent vagina, Müllerian agenesis.
Acquired: destruction of endometrium with curettage (Asherman syndrome), closure of cervix or vagina caused by traumatic injury, hysterectomy.

OTHER

Metabolic diseases (liver, kidney), malnutrition, rapid weight loss, exogenous obesity, endocrine abnormalities (Cushing syndrome, Graves disease, hypothyroidism).

AMNESIA

ICD-10CM #		
	F19.96	Other psychoactive substance use, unspecified with psychoactive substance-induced persisting amnestic disorder
	F44.0	Dissociative amnesia
	R41.2	Retrograde amnesia
	G45.4	Transient global amnesia

Degenerative diseases (e.g., Alzheimer, Huntington disease).
CVA (especially when involving thalamus, basal forebrain, and hippocampus).
Head trauma.
Postsurgical (e.g., mammillary body surgery, bilateral temporal lobectomy).
Infections (herpes simplex encephalitis, meningitis).
Wernicke-Korsakoff syndrome.
Cerebral hypoxia.
Hypoglycemia.
CNS neoplasms.
Creutzfeldt-Jakob disease.
Medications (e.g., midazolam and other benzodiazepines).
Psychosis.
Malingering.

AMNIOTIC FLUID α-FETOPROTEIN ELEVATION[36]

ICD-10CM # Z36 Encounter for antenatal screening of mother

CAUSES OF ELEVATED AMNIOTIC FLUID α-FETOPROTEIN

Craniospinal defect (open neural tube defect).
Omphalocele.
Gastroschisis.
Duodenal atresia.
Congenital nephrosis.
Cystic hygroma.
Unbalanced D/G dislocation.
Down, Tay-Sachs, Klinefelter, Turner syndromes.
Fetal tumors.
Epidermolysis bullosa.
Pilonidal sinus.
Rhesus disease.
Fetal demise.
Incorrect dates.
Multiple pregnancies.

ANAL ABSCESS AND FISTULA[86]

ICD-10CM #		
	K61.0	Anal abscess
	K61.1	Rectal abscess
	K61.3	Ischiorectal abscess
	K60.3	Anal fistula

Primary anal gland infection.
Secondary abscess:
- Inflammatory bowel disease:
  - Crohn disease.
  - Ulcerative colitis.

Infection:
- Tuberculosis.
- Actinomycosis.
- Threadworm.

Trauma.
Leukopenia.
Immunosuppression:
- HIV.
- Drugs.

Rectal cancer.
Diabetes mellitus.

ANAL INCONTINENCE[58]

ICD-10CM # R15.9 Full incontinence of feces

TRAUMATIC

Nerve injured in surgery.
Spinal cord injury.
Obstetric trauma.
Sphincter injury.

NEUROLOGIC

Spinal cord lesions.
Dementia.
Autonomic neuropathy (e.g., DM).
Obstetrics: pudendal nerve stretched during surgery.
Hirschsprung disease.

MASS EFFECT

Carcinoma of anal canal.
Carcinoma of rectum.
Foreign body.
Fecal impaction.
Hemorrhoids.

MEDICAL

Procidentia.
Inflammatory disease.
Diarrhea.
Laxative abuse.

PEDIATRIC

Congenital.
Meningocele.
Myelomeningocele.
Spina bifida.
After corrective surgery for imperforate anus.
Sexual abuse.
Encopresis.

ANAPHYLAXIS[49]

ICD-10CM # T78.2 Anaphylactic shock, unspecified, initial encounter

PULMONARY

Laryngeal edema.
Epiglottitis.
Foreign body aspiration.
Pulmonary embolus.
Asphyxiation.
Hyperventilation.

CARDIOVASCULAR

Myocardial infarction.
Arrhythmia.
Hypovolemic shock.
Cardiac arrest.

CNS

Vasovagal reaction.
CVA.
Seizure disorder.
Drug overdose.

ENDOCRINE

Hypoglycemia.
Pheochromocytoma.
Carcinoid syndrome.
Catamenial (progesterone-induced anaphylaxis).

PSYCHIATRIC

Vocal cord dysfunction syndrome.
Munchausen syndrome.
Panic attack/globus hystericus.

OTHER

Hereditary angioedema.
Cord urticaria.
Idiopathic urticaria.
Mastocytosis.
Serum sickness.
Idiopathic capillary leak syndrome.
Sulfite exposure.
Scombroid poisoning (tuna, blue fish, mackerel).

ANAPHYLAXIS MIMICS[69]

ICD-10CM # Varies with specific diagnosis

CONDITIONS THAT MIMIC ANAPHYLAXIS

Vasovagal episodes.
Acute pulmonary events:
- Acute asthmatic attacks.
- Acute pulmonary edema.
- Pulmonary embolus.
- Spontaneous pneumothorax.
- Foreign body aspiration.

Acute cardiac events:
- Supraventricular tachycardias.
- Acute myocardial infarction/ischemia.

Drug overdoses.
Insulin shock.
Carcinoid attacks.

ANAPHYLAXIS, PATHOPHYSIOLOGIC CLASSIFICATION[2]

ICD-10CM # T78.2 Anaphylactic shock, unspecified, initial encounter

PATHOPHYSIOLOGIC CLASSIFICATION OF ANAPHYLAXIS

IgE Dependent, Immunologic
Foods.
Drugs.
Insect stings and bites.
Exercise (food dependent).
Other causes.
IgE Independent, Immunologic
Immune aggregates.
IgG anti-IgA.
Cytotoxic.
Disturbance of arachidonic acid metabolism:
- Aspirin.
- Other nonsteroidal antiinflammatory drugs.

Activation of kallikrein-kinin contact system:
- Dialysis membranes.
- Radiocontrast media.

Multimediator recruitment:
- Complement.
- Clotting.
- Clot lysis.
- Kallikrein-kinin contact system.

Other causes.
Nonimmunologic
Direct mediator release from mast cells and basophils:
- Drugs, e.g., opiates.
- Physical factors, e.g., cold and sunlight.

Exercise.
c-kit Mutation (D816V).
Other causes.
Idiopathic

ANAPHYLACTOID SYNDROME OF PREGNANCY[1]

ICD-10CM # 088.113

CARDIOVASCULAR COLLAPSE, HYPOTENSION

Acute coronary syndromes, myocardial infarction.
Cardiomyopathy.
Pulmonary embolism.
Anesthesia complications, transfusion reaction.
Sepsis, systemic inflammatory response syndrome.

RESPIRATORY ARREST

Pulmonary embolism, air embolism.
Anesthesia complications, transfusion reaction.
Aspiration.

ALTERED MENTAL STATUS, SEIZURE

Eclampsia.
Cerebrovascular accident.
Hypoglycemia.

COAGULOPATHY

Disseminated intravascular coagulation.
Consumptive coagulopathy from hemorrhage.

ANDROGEN EXCESS, REPRODUCTIVE-AGE WOMAN

ICD-10CM #	E28.1	Androgen excess

Polycystic ovary syndrome.
Idiopathic.
Medications (e.g., anabolizing agents, testosterone, danazol).
Pregnancy (luteoma, hyperreaction luteinalis).
Sertoli-Leydig ovarian neoplasm.
Adrenal adenoma or hyperplasia.
Cushing syndrome.
Glucocorticoid resistance.
Hypothyroidism.
Hyperprolactinemia.

ANDROGEN RESISTANCE[62]

ICD-10CM #	E34.5	Androgen resistance syndrome

CONGENITAL OR DEVELOPMENTAL DISORDERS

Uncommon causes:
- Kennedy disease (spinal and bulbar muscular atrophy).
- Partial androgen insensitivity syndrome (AR mutations).
- 5α-reductase type 2 deficiency.
- Complete androgen insensitivity syndrome (female phenotype).

ACQUIRED DISORDERS

Common causes:
- AR antagonists (bicalutamide, nilutamide).
- Drugs (spironolactone, cyproterone acetate, marijuana, histamine 2 receptor antagonists).

Uncommon causes:
- Celiac disease.

ANEMIA, APLASTIC[45]

ICD-10CM #	D61.09	Other constitutional aplastic anemia

ACQUIRED APLASTIC ANEMIA

Secondary aplastic anemia.
Irradiation.
Drugs and chemicals.
Regular effects.
Cytotoxic agents.
Benzene.
Idiosyncratic reactions.
Chloramphenicol.
Nonsteroidal antiinflammatory drugs.
Antiepileptics.
Gold.
Other drugs and chemicals.
Viruses.
Epstein-Barr virus (infectious mononucleosis).
Hepatitis virus (non-A, non-B, non-C, non-G hepatitis).
Parvovirus (transient aplastic crisis, some pure red cell aplasia).
Human immunodeficiency virus (acquired immunodeficiency syndrome).
Immune diseases.
Eosinophilic fasciitis.
Hyperimmunoglobulinemia.
Thymoma and thymic carcinoma.
Graft-versus-host disease in immunodeficiency.
Paroxysmal nocturnal hemoglobinuria.
Pregnancy.
Idiopathic aplastic anemia.

INHERITED APLASTIC ANEMIA

Fanconi anemia.
Dyskeratosis congenita.
Shwachman-Diamond syndrome.
Reticular dysgenesis.
Amegakaryocytic thrombocytopenia.
Familial aplastic anemias.
Preleukemia (e.g., monosomy 7).
Nonhematologic syndromes (e.g., Down, Dubowitz, Seckel).

ANEMIA, APLASTIC, DUE TO DRUGS AND CHEMICALS[1]

ICD-10CM #	D61.1	Drug-induced aplastic anemia
	D61.2	Aplastic anemia due to other external agents
	D61.89	Other specified aplastic anemias and other bone marrow failure syndromes

Agents that regularly produce marrow depression as a major toxic effect when used in commonly employed doses or normal exposures:
- Cytotoxic drugs used in cancer chemotherapy.
- Alkylating agents (busulfan, melphalan, cyclophosphamide).
- Antimetabolites (antifolic compounds, nucleotide analogs), antimitotics (vincristine, vinblastine, colchicine).
- Some antibiotics (daunorubicin, doxorubicin [Adriamycin]).
- Benzene (and less often benzene-containing chemicals; kerosene, carbon tetrachloride, Stoddard solvent, chlorophenols).

Agents probably associated with aplastic anemia but with a relatively low probability relative to their use:
- Chloramphenicol.
- Insecticides.
- Antiprotozoals (quinacrine and chloroquine).
- NSAIDs (including phenylbutazone, indomethacin, ibuprofen, sulindac, diclofenac, naproxen, piroxicam, fenoprofen, fenbufen, aspirin).
- Anticonvulsants (hydantoins, carbamazepine, phenacemide, ethosuximide).
- Gold, arsenic, and other heavy metals such as bismuth and mercury.
- Sulfonamides as a class.
- Antithyroid medications (methimazole, methylthiouracil, propylthiouracil).
- Antidiabetes drugs (tolbutamide, carbutamide, chlorpropamide).
- Carbonic anhydrase inhibitors (acetazolamide, methazolamide, mesalazine).
- D-Penicillamine.
- 2-Chlorodeoxyadenosine.

Agents more rarely associated with aplastic anemia:
- Antibiotics (streptomycin, tetracycline, methicillin, ampicillin, mebendazole and albendazole, sulfonamides, flucytosine, mefloquine, dapsone).
- Antihistamines (cimetidine, ranitidine, chlorpheniramine).
- Sedatives and tranquilizers (chlorpromazine, prochlorperazine, piperacetazine, chlordiazepoxide, meprobamate, methyprylon, remoxipride).
- Antiarrhythmics (tocainide, amiodarone).
- Allopurinol (can potentiate marrow suppression by cytotoxic drugs).
- Ticlopidine.
- Methyldopa.
- Quinidine.
- Lithium.
- Guanidine.
- Canthaxanthin.
- Thiocyanate.
- Carbimazole.
- Cyanamide.
- Deferoxamine.
- Amphetamines.

ANEMIA, CAUSES IN PREGNANCY[30]

ICD-10CM #	D50.8	Other iron deficiency anemias
	D50.9	Iron deficiency anemia, unspecified
	D51.0	Vitamin B_{12} deficiency anemia due to intrinsic factor deficiency
	D51.1	Vitamin B_{12} deficiency anemia due to selective vitamin B_{12} malabsorption with proteinuria
	D51.3	Other dietary vitamin B_{12} deficiency anemia
	D51.8	Other vitamin B_{12} deficiency anemias

D52.0	Dietary folate deficiency anemia
D52.1	Drug-induced folate deficiency anemia
D52.8	Other folate deficiency anemias
D52.9	Folate deficiency anemia, unspecified
D53.1	Other megaloblastic anemias, not elsewhere classified
D53.0	Protein deficiency anemia
D53.2	Scorbutic anemia
D53.8	Other specified nutritional anemias
D53.9	Nutritional anemia, unspecified
D64.0	Hereditary sideroblastic anemia
D64.1	Secondary sideroblastic anemia due to disease
D64.2	Secondary sideroblastic anemia due to drugs and toxins
D64.3	Other sideroblastic anemias

CAUSES OF ANEMIA DURING PREGNANCY

Common causes—85% of anemia:
- Physiologic anemia.
- Iron deficiency.

Uncommon causes:
- Folic acid deficiency.
- Vitamin B_{12} deficiency (due to the rapid increase in bariatric surgery).
- Hemoglobinopathies:
  - Sickle cell disease.
  - Hemoglobin SC.
  - β-Thalassemia minor.
- Bariatric surgery.
- GI bleeding.

Rare causes:
- Hemoglobinopathies.
  - β-Thalassemia major.
  - α-Thalassemia.

Syndromes of chronic hemolysis:
- Hereditary spherocytosis.
- Paroxysmal nocturnal hemoglobinuria.

Hematologic malignancy.

ANEMIA, DRUG-INDUCED[39]

ICD-10CM #	D61.1	Drug-induced aplastic anemia

DRUGS THAT MAY INTERFERE WITH RED CELL PRODUCTION BY INDUCING MARROW SUPPRESSION OR APLASIA

Alcohol.
Antineoplastic drugs.
Antithyroid drugs.
Antibiotics.
Oral hypoglycemic agents.
Phenylbutazone.
Azidothymidine (AZT).

DRUGS THAT INTERFERE WITH VITAMIN B_{12}, FOLATE, OR IRON ABSORPTION OR UTILIZATION

Nitrous oxide.
Anticonvulsant drugs.
Antineoplastic drugs.
Isoniazid.
Cycloserine A.

DRUGS CAPABLE OF PROMOTING HEMOLYSIS

Immune Mediated

Penicillins.
Quinine.
α-methyldopa.
Procainamide.
Mitomycin C.

Oxidative Stress

Antimalarials.
Sulfonamide drugs.
Nalidixic acid.

DRUGS THAT MAY PRODUCE OR PROMOTE BLOOD LOSS

Aspirin.
Alcohol.
Nonsteroidal antiinflammatory agents.
Corticosteroids.
Anticoagulants.

ANEMIA, HYPOCHROMIC[45]

ICD-10CM #	D50.8	Other Iron deficiency anemias
	D50.9	Iron deficiency anemia, unspecified
	D64.0	Hereditary sideroblastic anemia
	D64.1	Secondary sideroblastic anemia due to disease
	D64.2	Secondary sideroblastic anemia due to drugs and toxins
	D64.3	Other sideroblastic anemias

DECREASED BODY IRON STORES

Iron deficiency anemia.

NORMAL OR INCREASED BODY IRON STORES

Impaired iron metabolism.
Anemia of chronic disease.
Defective absorption, transport, or use of iron.
Disorders of globin synthesis:
- Thalassemia.
- Other microcytic hemoglobinopathies.

Disorders of heme synthesis: sideroblastic anemias:
- Hereditary.
- Acquired.

ANEMIA, LOW RETICULOCYTE COUNT[3]

ICD-10CM #	D64.9	Anemia, unspecified

MICROCYTIC ANEMIA (MCV <80)

Iron deficiency.
Thalassemia minor.
Sideroblastic anemia.
Lead poisoning.

MACROCYTIC ANEMIA (MCV >100)

Megaloblastic anemias.
Folate deficiency.
Vitamin B_{12} deficiency.
Drug-induced megaloblastic anemia.
Nonmegaloblastic macrocytosis.
Liver disease.
Hypothyroidism.

NORMOCYTIC ANEMIA (MCV 80-100)

Early iron deficiency.
Aplastic anemia.
Myelophthisic disorders.
Endocrinopathies.
Anemia of chronic disease.
Uremia.
Mixed nutritional deficiency.

ANEMIA, MEGALOBLASTIC[82]

ICD-10CM #	D51.0	Vitamin B_{12} deficiency anemia due to intrinsic factor deficiency
	D51.1	Vitamin B_{12} deficiency anemia due to selective vitamin B_{12} malabsorption with proteinuria
	D51.3	Other dietary vitamin B_{12} deficiency anemia
	D51.8	Other vitamin B_{12} deficiency anemias
	D52.0	Dietary folate deficiency anemia
	D52.1	Drug-induced folate deficiency anemia
	D52.8	Other folate deficiency anemias
	D52.9	Folate deficiency anemia, unspecified
	D53.1	Other megaloblastic anemias, not elsewhere classified
	D53.0	Protein deficiency anemia
	D53.2	Scorbutic anemia
	D53.8	Other specified nutritional anemias
	D53.9	Nutritional anemia, unspecified

COBALAMIN (CBL) DEFICIENCY

Nutritional CBL Deficiency (Insufficient CBL Intake)

Vegetarians, vegans, breastfed infants of mothers with pernicious anemia.

Abnormal Intragastric Events (Inadequate Proteolysis of Food CBL)

Atrophic gastritis, partial gastrectomy with hypochlorhydria.

Loss/Atrophy of Gastric Oxyntic Mucosa (Deficient Intrinsic Factor [If] Molecules)
Total or partial gastrectomy, pernicious anemia (PA), caustic destruction (lye).
Abnormal Events in Small Bowel Lumen
Inadequate pancreatic protease (R-CBL not degraded, CBL not transferred to IF).
  Insufficiency of pancreatic protease—pancreatic insufficiency.
  Inactivation of pancreatic protease—Zollinger-Ellison syndrome.
Usurping of luminal CBL (inadequate CBL binding to IF).
  By bacteria—stasis syndromes (blind loops, pouches of diverticulosis, strictures, fistulas, anastomoses); impaired bowel motility (scleroderma, pseudoobstruction), hypogammaglobulinemia.
  By *Diphyllobothrium latum*.
Disorders of Ileal Mucosa/IF Receptors (IF-CBL not Bound to IF Receptors)
Diminished or absent IF receptors—ileal bypass/resection/fistula.
Abnormal mucosal architecture/function—tropical/nontropical sprue, Crohn disease, TB ileitis, infiltration by lymphomas, amyloidosis.
IF-/post IF-receptor defects—Imerslund-Gräsbeck syndrome, TC II deficiency.
Drug-induced effects (slow K, biguanides, cholestyramine, colchicine, neomycin, PAS).

DISORDERS OF PLASMA CBL TRANSPORT (TC II-CBL NOT DELIVERED TO TC II RECEPTORS)

Congenital TC II deficiency, defective binding of TC II-CBL to TC II receptors (rare).

METABOLIC DISORDERS (CBL NOT UTILIZED BY CELL)

Inborn enzyme errors (rare).
Acquired disorders: (CBL oxidized to cob[III] alamin)—N_2O inhalation.

FOLATE DEFICIENCY

Nutritional Causes
Decreased dietary intake—poverty and famine (associated with kwashiorkor, marasmus), institutionalized individuals (psychiatric/nursing homes), chronic debilitating disease/goats' milk (low in folate), special diets (slimming), cultural/ethnic cooking techniques (food folate destroyed) or habits (folate-rich foods not consumed).
Decreased diet and increased requirements:
  Physiologic: pregnancy and lactation, prematurity, infancy.
  Pathologic: intrinsic hematologic disease (autoimmune hemolytic disease), drugs, malaria; hemoglobinopathies (SS, thalassemia), RBC membrane defects (hereditary spherocytosis, paroxysmal nocturnal hemoglobinopathy); abnormal hematopoiesis (leukemia/lymphoma, myelodysplastic syndrome, agnogenic myeloid metaplasia with myelofibrosis); infiltration with malignant disease; dermatologic (psoriasis).
Folate Malabsorption
With normal intestinal mucosa:
  Some drugs (controversial).
  Congenital folate malabsorption (rare).
  With mucosal abnormalities—tropical and nontropical sprue, regional enteritis.
Defective Cellular Folate Uptake—Familial Aplastic Anemia (Rare), Inadequate Cellular Utilization
Folate antagonists (methotrexate).
Hereditary enzyme deficiencies involving folate.
Drugs (Multiple Effects on Folate Metabolism)
Alcohol, sulfasalazine, triamterene, pyrimethamine, trimethoprim-sulfamethoxazole, diphenylhydantoin, barbiturates.

MISCELLANEOUS MEGALOBLASTIC ANEMIAS (NOT CAUSED BY CBL OR FOLATE DEFICIENCY)

Congenital Disorders of DNA Synthesis (Rare)
Orotic aciduria, Lesch-Nyhan syndrome, congenital dyserythropoietic anemia.
Acquired Disorders of DNA Synthesis
Thiamine-responsive megaloblastosis (rare).
Malignancy—erythroleukemia—refractory sideroblastic anemias—all antineoplastic drugs that inhibit DNA synthesis.
Toxins: alcohol.

ANEMIA, MICROCYTIC, HYPOCHROMIC, DIFFERENTIAL DIAGNOSIS[44]

ICD-10CM #	D50.8	Other iron deficiency anemias
	D50.9	Iron deficiency anemia, unspecified
	D64.0	Hereditary sideroblastic anemia
	D64.1	Secondary sideroblastic anemia due to disease
	D64.2	Secondary sideroblastic anemia due to drugs and toxins
	D64.3	Other sideroblastic anemias

DIFFERENTIAL DIAGNOSIS OF MICROCYTIC HYPOCHROMIC ANEMIA

Decreased Body Iron Stores
Iron deficiency anemia.
Normal or Increased Body Iron Stores
Anemia of chronic disease.
Defective absorption, transport, or use of iron.
Iron-refractory, iron deficiency anemia after parenteral iron.
Atransferrinemia.
Aceruloplasminemia.
Divalent metal transporter 1 (DMT1 or SLC11A2) deficiency.
Ferroportin-associated hemochromatosis with impaired iron export (type 4A).
Heme oxygenase 1 deficiency.
Disorders of globin synthesis.
Decreased Body Iron Stores
Thalassemia.
  Other microcytic hemoglobinopathies.
  Disorders of heme synthesis.
Sideroblastic anemias.
  Hereditary.
  Acquired.

ANERGY, CUTANEOUS[82]

ICD-10CM #	D89.9	Disorder involving the immune mechanism, unspecified

IMMUNOLOGIC

Acquired (AIDS, acute leukemia, carcinoma, CLL, Hodgkin lymphoma, NHL).
Congenital (ataxia-telangiectasia, Di George syndrome, severe combined immunodeficiency, Wiskott-Aldrich syndrome).

INFECTIONS

Bacterial (bacterial pneumonia, brucellosis).
Disseminated mycotic infections.
Mycobacterial (lepromatous leprosy, TB).
Viral (varicella, hepatitis, influenza, mononucleosis, measles, mumps).

IMMUNOSUPPRESSIVE MEDICATIONS

Systemic corticosteroids.
Methotrexate, cyclophosphamide.
Rifampin.

OTHER

Alcoholic cirrhosis, biliary cirrhosis, sarcoidosis, rheumatic disease.
Diabetes, Crohn disease, uremia.
Anemia, pyridoxine deficiency, sickle cell anemia.
Burns, malnutrition, pregnancy, old age, surgery.

ANEURYSMS, THORACIC AORTA

ICD-10CM #	I71.2	Thoracic aortic aneurysm, without rupture

Trauma.
Infection.
Inflammatory (syphilis, Takayasu disease).
Collagen vascular disease (RA, ankylosing spondylitis).
Annuloaortic ectasia (Marfan syndrome, Ehlers-Danlos syndrome).
Congenital.
Coarctation.
Cystic medial necrosis.

ANHIDROSIS

ICD-10CM #	L74.0	Miliaria rubra
	L74.1	Miliaria crystallina
	L74.2	Miliaria profunda

Drugs (anticholinergics).
Dehydration.
Hysteria.

Obstruction of sweat ducts (e.g., inflammation, miliaria).
Local radiant heat or pressure.
CNS lesions (medulla, hypothalamus, pons).
Spinal cord lesions.
Lesions of sympathetic nerves.
Congenital sweat gland disturbances.

ANION GAP ACIDOSIS[88]

ICD-10CM # E87.2 Acidosis

CLINICAL CAUSES OF HIGH ANION GAP AND NORMAL ANION GAP ACIDOSIS

High Anion Gap

Ketoacidosis:
- Diabetic ketoacidosis (acetoacetate).
- Alcoholic (β-hydroxybutyrate).
- Starvation.

Lactic acid acidosis:
- L-Lactic acid acidosis (types A and B).
- D-Lactic acid acidosis.
- Renal failure: sulfate, phosphate, urate, hippurate.

Ingestions (toxins and their metabolites):
- Ethylene glycol → glycolate, oxalate.
- Methyl alcohol → formate.
- Salicylate → ketones, lactate, salicylate.
- Paraldehyde → organic anions.
- Toluene → hippurate (commonly presents with normal anion gap).
- Propylene glycol → lactate.
- Pyroglutamic acidosis (acetaminophen use) → 5-oxoproline.

Normal Anion Gap

GI loss of HCO_3^- (negative urine anion gap):
- Diarrhea.
- Fistula, external.

Renal loss of HCO_3^- or failure to excrete NH_4^+ (positive urine anion gap):
- Proximal renal tubular acidosis (RTA type 2).
- Acetazolamide.
- Classic distal renal tubular acidosis (low serum K^+) RTA type 1.
- Generalized distal renal tubular defect (high serum K^+) RTA type 4.

Miscellaneous:
- NH_4Cl ingestion.
- Sulfur ingestion.
- Dilutional acidosis.
- Late stages in treatment of diabetic ketoacidosis.

ANION GAP INCREASE

ICD-10CM # E87.8 Other disorders of electrolyte and fluid balance, not elsewhere classified

Uremia.
Ketoacidosis (diabetic, starvation, alcoholic).
Lactic acidosis.
Ethylene glycol poisoning.
Salicylate overdose.
Methanol poisoning.

ANISOCORIA

ICD-10CM # H57.02 Anisocoria

Mydriatic or miotic drugs.
Prosthetic eye.
Inflammation (keratitis, iridocyclitis).
Infections (herpes zoster, syphilis, meningitis, encephalitis, TB, diphtheria, botulism).
Subdural hemorrhage.
Cavernous sinus thrombosis.
Intracranial neoplasm.
Cerebral aneurysm.
Glaucoma.
CNS degenerative diseases.
Internal carotid ischemia.
Toxic polyneuritis (alcohol, lead).
Adie syndrome.
Horner syndrome.
DM.
Trauma.
Congenital.

ANKLE AND FOOT PAIN[42]

ICD-10CM # M25.579 Pain in unspecified ankle and joint pain in unspecified foot

Anterior ankle	Anterior impingement. Ankle arthritis or synovitis. Osteochondral defect or lesion (cartilage injury). Loose body within the joint. Talar avascular necrosis. Talar stress fracture. Tenosynovitis of the extensor hallucis longus, extensor digitorum longus. Deep (central) or superficial (anterolateral) peroneal nerve injury. Saphenous (anteromedial) nerve injury.
Posterior ankle	Os trigonum (accessory ossicle involving the posterior lateral tubercle of the talus). Posterior impingement. Retrocalcaneal bursitis. Achilles tendinopathy. Flexor hallucis longus tendinopathy or stenosis.
Posterolateral ankle	Peroneal tendinopathy. Subfibular impingement caused by flatfoot and impingement. Fibular stress fracture. Sural nerve injury. Lateral ligament injury (sprain).
Posteromedial ankle	Posterior tibial tendinopathy. Flexor digitorum longus or flexor hallucis longus tendinopathy. Tibial stress fracture. Medial malleolar stress fracture. Tarsal tunnel syndrome. Tibial nerve injury. Deltoid ligament injury.
Heel	Achilles insertional tendinopathy. Inflammatory enthesitis. Plantar fasciitis. Haglund disease (pump bump). Calcaneal stress fracture.
Hindfoot	Subtalar, talonavicular, or calcaneocuboid arthritis or synovitis. Posterior tibial tendon dysfunction or tendinopathy (medial) or peroneal tendon dysfunction (lateral). Occult fracture of the talus, calcaneus cuboid, or navicular Accessory navicular.
Midfoot	Insertional tendinopathy (peroneal, posterior tibial, tibialis anterior). Arthritis or synovitis (navicular–cuneiform, cuneiform–metatarsal, cuboid–metatarsal). Navicular stress fracture. Spring ligament strain.
Forefoot	
First ray, first MTP joint, hallux	Arthritis or synovitis MTP (hallux limitus/rigidus) and IP joints. Hallux valgus. Hallux varus. Sesamoiditis. Gouty monoarthritis.
Second to fifth rays, MTP joints, lesser toes	Arthritis or synovitis (MTP, proximal and distal IP joints). Lesser toe deformities (hammer and claw toes). Metatarsalgia. MTP instability. MTP dislocations. Morton neuroma (interdigital neuralgia). Stress fracture of the metatarsals. Bunionette (fifth metatarsal phalangeal deviation). Rheumatoid nodules. Bursitis (intermetatarsal or adventitious). Ulcer. Infection.

IP, Interphalangeal; *MTP,* metatarsophalangeal.

ANORECTAL DISEASE, AIDS PATIENT[26]

ICD-10CM # Varies with specific diagnosis

DIFFERENTIAL DIAGNOSIS OF ANORECTAL DISEASE IN PATIENTS WITH AIDS

Infections

Bacteria

*Chlamydia trachomatis.**
Lymphogranuloma venereum.
*Neisseria gonorrhoeae.**
Shigella flexneri.
Mycobacterium tuberculosis.

Protozoa

Entamoeba histolytica.
Leishmania donovani.

Viruses

HSV.*

*More frequent diagnosis.

Cytomegalovirus.*
Fungi
Candida albicans.
Histoplasma capsulatum.
Neoplasms
Lymphoma.*
Kaposi sarcoma.
Squamous cell carcinoma.
Cloacogenic carcinoma.
Condyloma acuminatum.
Other
Idiopathic ulcers.*
Perirectal abscess, fistula.*

* More frequent diagnosis.

ANOREXIA[86]

ICD-10CM # R63.0 Anorexia

SELECTED CAUSES OF ANOREXIA

Gastrointestinal Tract/Liver
Gastric outlet obstruction or small bowel obstruction.
Gastric cancer.
Hepatic metastases.
Acute viral hepatitis.
Metabolic
Addison disease.
Hypopituitarism.
Hyperparathyroidism.
Functional
Extremely unpleasant sight/smell.
Systemic
Chronic pain.
Renal failure.
Severe congestive heart failure.
Respiratory failure.
Psychiatric
Depression.
Anorexia nervosa.
Medications
Digoxin.
Narcotic analgesics.
Diuretics.
Antihypertensives.
Chemotherapeutic agents.
Amphetamines.
Miscellaneous
Excessive smoking.
Excessive alcohol intake.
Oral cavity disease.
Thiamine deficiency.
Early pregnancy.
Hypogeusia or dysgeusia.

ANOVULATION

ICD-10CM #	N97.0	Female infertility associated with anovulation

Anorexia and bulimia.
Strenuous exercise.
Weight loss/malnutrition.
Empty sella syndrome.
Pituitary disorders (infarction, infection, trauma, irradiation, surgery, microadenomas, macroadenomas).
Idiopathic hypopituitarism.
Drug induced.
Thyroid dysfunction (hypothyroidism, hyperthyroidism).
Systemic diseases (e.g., liver disease).
Adrenal hyperfunction (Cushing syndrome, congenital adrenal hyperplasia).
Polycystic ovarian syndrome.
Isolated gonadotropin deficiency.

APPENDICITIS, DIFFERENTIAL DIAGNOSIS IN PREGNANCY[30]

ICD-10CM # Varies with specific diagnosis

DIFFERENTIAL DIAGNOSIS OF APPENDICITIS DURING PREGNANCY

Gynecologic Conditions
Ruptured ovarian cyst.
Adnexal torsion.
Pelvic inflammatory disease or salpingitis.
Endometriosis.
Ovarian cancer.
Obstetrical Causes
Abruptio placentae.
Chorioamnionitis.
Endometritis.
Uterine fibroid degeneration.
Labor (preterm or term).
Viscus perforation after abortion.
Ruptured ectopic pregnancy.
Gastrointestinal Causes
Crohn disease.
Colonic diverticulitis (right side).
Cholecystitis.
Pancreatitis.
Mesenteric lymphadenitis.
Gastroenteritis.
Colon cancer.
Intestinal obstruction.
Hernia (incarcerated inguinal or internal).
Colonic intussusception.
Ruptured Meckel diverticulum.
Colonic perforation.
Acute mesenteric ischemia.
Other Causes
Pyelonephritis.
Urolithiasis.

APPETITE LOSS IN INFANTS AND CHILDREN[43]

ICD-10CM #	R63.0	Anorexia
	F50.8	Other eating disorders
	F98.29	Other feeding disorders of infancy and early childhood

ORGANIC DISEASE

Infection (Acute or Chronic) Neurologic
Congenital degenerative disease.
Hypothalamic lesion.
Increased intracranial pressure (including a brain tumor).
Swallowing disorders (neuromuscular).
Gastrointestinal
Oral lesions (e.g., thrush or herpes simplex).
Gastroesophageal reflux.
Obstruction (especially with gastric or intestinal distention).
Inflammatory bowel disease.
Celiac disease.
Constipation.
Cardiac
Congestive heart failure (especially associated with cyanotic lesions).
Metabolic
Renal failure and/or renal tubule acidosis.
Liver failure.
Congenital metabolic disease.
Lead poisoning.
Nutritional
Marasmus.
Iron deficiency.
Zinc deficiency.
Fever
RA.
Rheumatic fever.
Drugs
Morphine.
Digitalis.
Antimetabolites.
Methylphenidate.
Amphetamines.
Miscellaneous
Prolonged restriction of oral feedings, beginning in the neonatal period.
Systemic lupus erythematosus (SLE).
Tumor.

PSYCHOLOGIC FACTORS

Anxiety, fear, depression, mania (limbic influence on the hypothalamus).
Avoidance of symptoms associated with meals (abdominal pain, diarrhea, bloating, urgency, dumping syndrome).
Anorexia nervosa.
Excessive weight loss and food aversion in athletes, simulating anorexia nervosa.

ARTERIAL OCCLUSION[33]

ICD-10CM #	I74.3	Embolism and thrombosis of arteries of the lower extremities
	I74.2	Embolism and thrombosis of arteries of the upper extremities

Thromboembolism (post-MI, mitral stenosis, rheumatic valve disease, atrial fibrillation, atrial myxoma, marantic endocarditis, bacterial endocarditis, Libman-Sacks endocarditis).
Atheroembolism (microemboli composed of cholesterol, calcium, and platelets from proximal atherosclerotic plaques).
Arterial thrombosis (endothelial injury, altered arterial blood flow, trauma, severe atherosclerosis, acute vasculitis).
Vasospasm.
Trauma.
Hypercoagulable states.
Miscellaneous (irradiation, drugs, infections, necrotizing).

ARTHRITIS AND ABDOMINAL PAIN

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	R10.817	Generalized abdominal tenderness
	M02.9	Reactive arthropathy

Viral syndrome.
Inflammatory bowel disease.
Celiac disease.
Vasculitis.
SLE.
RA.
Scleroderma.
Amyloidosis.
Chronic hepatitis C.
Whipple disease.
Polyarteritis nodosa.
Behçet disease.
Familial Mediterranean fever.
Blind loop syndrome.
Babesiosis.
Lyme disease.
Ehrlichiosis.

ARTHRITIS AND DIARRHEA

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	R19.7	Diarrhea, unspecified

Viral syndrome.
Inflammatory bowel disease.
Celiac disease.
Whipple disease.
Enterogenic (bacterial) reactive arthritis.
Collagenous colitis.
Behçet disease.
Hyperthyroidism.
Spondyloarthropathy.
Blind loop syndrome.

ARTHRITIS AND EYE LESIONS[16]

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	M02.3	Reiter disease
	M02.9	Reactive arthropathy

SLE.
Sjögren syndrome.
Behçet syndrome.
Sarcoidosis.
Subacute bacterial endocarditis (SBE).
Lyme disease.
Granulomatosis with polyangiitis.
Giant cell arteritis.
Takayasu arteritis.
RA, JRA.
Scleroderma.
Inflammatory bowel disease.
Whipple disease.
Ankylosing spondylitis.
Reactive arthritis.
Psoriatic arthritis.

ARTHRITIS AND HEART MURMUR[16]

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	I01.8	Other acute rheumatic heart disease
	M02.9	Reactive arthropathy

SBE.
Cardiac myxoma.
Ankylosing spondylitis.
Reactive arthritis.
Acute rheumatic fever.
RA.
SLE with Libman-Sacks endocarditis.
Relapsing polychondritis.

ARTHRITIS AND MUSCLE WEAKNESS[18]

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	M62.9	Disorder of muscle, unspecified
	M02.9	Reactive arthropathy

RA.
Ankylosing spondylitis.
Polymyositis.
Dermatomyositis.
SLE, scleroderma, mixed connective tissue disease.
Sarcoidosis.
HIV-associated arthritis.
Whipple disease.

ARTHRITIS AND RASH[16]

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	R21	Rash and other nonspecific skin eruption
	M02.9	Reactive arthropathy

Chronic urticaria.
Vasculitic urticaria.
SLE.
Dermatomyositis.
Polymyositis.
Psoriatic arthritis.
Reactive arthritis.
Chronic sarcoidosis.
Serum sickness.
Sweet syndrome.
Leprosy.

ARTHRITIS AND SUBCUTANEOUS NODULES[16]

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	A18.4	Tuberculosis of skin and subcutaneous tissue
	M02.9	Reactive arthropathy

RA.
Gout.
Pseudogout (rare).
Sarcoidosis.
Light chain (LA) amyloidosis (primary, multiple myeloma).
Acute rheumatic fever (ARF).
Hemochromatosis.
Whipple disease.
Multicentric reticulohistiocytosis.

ARTHRITIS AND WEIGHT LOSS[16]

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	R63.4	Abnormal weight loss
	M02.9	Reactive arthropathy

Severe RA.
RA with vasculitis.
Reactive arthritis.
RA or psoriatic arthritis or ankylosing spondylitis with amyloidosis.
Cancer.
Enteropathic arthritis (Crohn, ulcerative colitis).
HIV infection.
Whipple disease.
Blind loop syndrome.
Scleroderma with intestinal bacterial overgrowth.

ARTHRITIS OR EXTREMITY PAIN, IN CHILDREN AND ADOLESCENTS[53]

ICD-10CM #		
	M02.9	Reactive arthropathy

CAUSES OF ARTHRITIS OR EXTREMITY PAIN IN CHILDREN AND ADOLESCENTS

Rheumatic and Inflammatory Diseases
Juvenile idiopathic arthritis.
Systemic lupus erythematosus.
Juvenile dermatomyositis.
Polyarteritis.
Vasculitis.
Scleroderma.
Sjögren syndrome.
Behçet disease.
Overlap syndromes.
Granulomatosis with polyangiitis (Wegener granulomatosis).
Sarcoidosis.
Kawasaki syndrome.
Henoch-Schönlein purpura.
Chronic recurrent multifocal osteomyelitis.
Seronegative Spondyloarthropathies
Juvenile ankylosing spondylitis.
Inflammatory bowel disease.
Psoriatic arthritis.
Reactive arthritis associated with urethritis, iridocyclitis, and mucocutaneous lesions.
Infectious Illnesses
Bacterial arthritis (septic arthritis, *Staphylococcus aureus,* pneumococcus, gonococcus, *Haemophilus influenzae*).
Lyme disease.

Viral illness (parvovirus, rubella, mumps, Epstein-Barr virus, hepatitis B).
Fungal arthritis.
Mycobacterial infection.
Spirochetal infection.
Endocarditis.
Reactive Arthritis
Acute rheumatic fever.
Reactive arthritis (postinfectious due to *Shigella, Salmonella, Yersinia, Chlamydia,* or meningococcus).
Serum sickness.
Toxic synovitis of the hip.
Postimmunization.
Immunodeficiencies
Hypogammaglobulinemia.
Immunoglobulin A deficiency.
Human immunodeficiency virus.
Congenital and Metabolic Disorders
Gout.
Pseudogout.
Mucopolysaccharidoses.
Thyroid disease (hypothyroidism, hyperthyroidism).
Hyperparathyroidism.
Vitamin C deficiency (scurvy).
Hereditary connective tissue disease (Marfan syndrome, Ehlers-Danlos syndrome).
Fabry disease.
Farber disease.
Amyloidosis (familial Mediterranean fever).
Bone and Cartilage Disorders
Trauma.
Patellofemoral syndrome.
Hypermobility syndrome.
Osteochondritis dissecans.
Avascular necrosis (including Legg-Calvé-Perthes disease).
Hypertrophic osteoarthropathy.
Slipped capital femoral epiphysis.
Osteolysis.
Benign bone tumors (including osteoid osteoma).
Histiocytosis.
Rickets.
Neuropathic Disorders
Peripheral neuropathies.
Carpal tunnel syndrome.
Charcot joints.
Neoplastic Disorders
Leukemia.
Neuroblastoma.
Lymphoma.
Bone tumors (osteosarcoma, Ewing sarcoma).
Histiocytic syndromes.
Synovial tumors.
Hematologic Disorders
Hemophilia.
Hemoglobinopathies (including sickle cell disease).
Miscellaneous Disorders
Pigmented villonodular synovitis.
Plant-thorn synovitis (foreign body arthritis).
Myositis ossificans.
Eosinophilic fasciitis.
Tendinitis (overuse injury).
Raynaud phenomenon.
Pain Syndromes
Fibromyalgia.
Growing pains.
Depression (with somatization).
Reflex sympathetic dystrophy.
Regional myofascial pain syndromes.

ARTHRITIS, AXIAL SKELETON

ICD-10CM #		
	M45.9	Ankylosing spondylitis of unspecified sites in spine
	L40.54	Psoriatic juvenile arthropathy
	L40.59	Other psoriatic arthropathy
	M15.9	Polyosteoarthritis, unspecified
	M45.9	Ankylosing spondylitis of unspecified sites in spine

RA.
Psoriatic arthritis.
Reiter syndrome (reactive arthritis).
Ankylosing spondylitis.
Juvenile RA.
Degenerative disease of the nucleus pulposus.
Spondylosis deformans.
Diffuse idiopathic skeletal hyperostosis (DISH).
Alkaptonuria.
Infection.

ARTHRITIS, CHRONIC, MONOARTICULAR OR OLIGOARTICULAR, INFECTIOUS CAUSES[10]

ICD-10CM #	Varies with specific diagnosis

INFECTIOUS CAUSES OF CHRONIC MONOARTICULAR OR OLIGOARTICULAR ARTHRITIS

Bacterial
Borrelia burgdorferi.
Tropheryma whipplei.
Treponema pallidum.
Nocardia spp.
Fungi
Candida spp.
Cryptococcus neoformans.
Blastomyces dermatitidis.
Coccidioides spp.
Paracoccidioides brasiliensis.
Sporothrix schenckii.
Aspergillus spp. and other molds, including *Rhizopus, Scedosporium*, and *Fusarium.*
Mycobacteria
Mycobacterium tuberculosis.
M. kansasii.
M. marinum.
M. avium-intracellulare complex.
M. terrae.
M. fortuitum, M. chelonae, M. abscessus.
M. haemophilum.
M. leprae.
Parasites
Helminths.
Filariae.

ARTHRITIS, FEVER, AND RASH[16]

ICD-10CM #		
	M00.9	Pyogenic arthritis, unspecified
	M02.9	Reactive arthropathy
	R21	Rash and other nonspecific skin eruption
	R50.9	Fever, unspecified

Rubella, parvovirus B19.
Gonococcemia, meningococcemia.
Secondary syphilis, Lyme borreliosis.
Adult acute rheumatic fever, adult Still disease, adult Kawasaki disease.
Vasculitic urticaria.
Acute sarcoidosis.
Familial Mediterranean fever.
Hyperimmunoglobulinemia D and periodic fever syndrome.

ARTHRITIS, MONOARTICULAR AND OLIGOARTICULAR[7]

ICD-10CM #		
	M19.90	Unspecified osteoarthritis, unspecified site
	M01.X0	Direct infection of unspecified joint in infectious and parasitic diseases classified elsewhere
	M13.10	Monoarthritis, not elsewhere classified, unspecified site

Septic arthritis (*S. aureus, Neisseria gonorrhoeae,* meningococci, streptococci, *Streptococcus pneumoniae,* enteric gram-negative bacilli).
Crystalline-induced arthritis (gout, pseudogout, calcium oxalate, hydroxyapatite and other basic calcium/phosphate crystals).
Traumatic joint injury.
Hemarthrosis.
Monoarticular or oligoarticular flare of an inflammatory polyarticular rheumatic disease (RA, psoriatic arthritis, Reiter syndrome [reactive arthritis], SLE).

ARTHRITIS, PEDIATRIC AGE[43]

ICD-10CM #		
	M01.X0	Direct infection of unspecified joint in infectious and parasitic diseases classified elsewhere
	M08.00	Unspecified juvenile rheumatoid arthritis of unspecified site

	M08.3	Juvenile rheumatoid polyarthritis (seronegative)
	M08.40	Pauciarticular juvenile rheumatoid arthritis, unspecified site

RHEUMATIC DISEASES OF CHILDHOOD

Acute rheumatic fever.
SLE.
Juvenile ankylosing spondylitis.
Polymyositis and dermatomyositis.
Vasculitis.
Scleroderma.
Psoriatic arthritis.
Mixed connective tissue disease and overlap syndromes.
Kawasaki disease.
Behçet syndrome.
Familial Mediterranean fever.
Reiter syndrome (reactive arthritis).
Reflex sympathetic dystrophy.
Fibromyalgia (fibrositis).

INFECTIOUS DISEASES

Bacterial arthritis.
Viral or postviral arthritis.
Fungal arthritis.
Osteomyelitis.
Reactive arthritis.

NEOPLASTIC DISEASES

Leukemia.
Lymphoma.
Neuroblastoma.
Primary bone tumors.

NONINFLAMMATORY DISORDERS

Trauma.
Avascular necrosis syndromes.
Osteochondroses.
Slipped capital femoral epiphysis.
Diskitis.
Patellofemoral dysfunction (chondromalacia patellae).
Toxic synovitis of the hip.
Overuse syndromes.

GENETIC OR CONGENITAL SYNDROMES

Hematologic Disorders

Sickle cell disease.
Hemophilia.

INFLAMMATORY BOWEL DISEASE

Miscellaneous

Growing pains.
Psychogenic arthralgias (conversion reactions).
Hypermobility syndrome.
Villonodular synovitis.
Foreign body arthritis.

ARTHRITIS, POLYARTICULAR

ICD-10CM #	M15.0	Primary generalized (osteo)arthritis
	M12.89	Other specific arthropathies, not elsewhere classified, multiple sites
	M08.3	Juvenile rheumatoid polyarthritis (seronegative)

RA, juvenile (rheumatoid) polyarthritis.
SLE, other connective tissue diseases, erythema nodosum, palindromic rheumatism, relapsing polychondritis.
Psoriatic arthritis, ankylosing spondylitis.
Sarcoidosis.
Lyme arthritis, bacterial endocarditis, *Neisseria gonorrhoeae* infection, rheumatic fever, Reiter disease (reactive arthritis).
Crystal deposition disease.
Hypersensitivity to serum or drugs.
Hepatitis B, HIV, rubella, mumps.
Other: serum sickness, leukemias, lymphomas, enteropathic arthropathy, Whipple disease, Behçet syndrome, Henoch-Schönlein purpura, familial Mediterranean fever, hypertrophic pulmonary osteoarthropathy.

ASCITES

ICD-10CM #	R18.0	Malignant ascites
	C78.6	Secondary malignant neoplasm of retroperitoneum and peritoneum
	I89.8	Other specified noninfective disorders of lymphatic vessels and lymph nodes

Hypoalbuminemia: nephrotic syndrome, protein-losing gastroenteropathy, starvation.
Cirrhosis.
Hepatic congestion: CHF, constrictive pericarditis, tricuspid insufficiency, hepatic vein obstruction (Budd-Chiari syndrome), inferior vena cava or portal vein obstruction.
Peritoneal infections: TB and other bacterial infections, fungal diseases, parasites.
Neoplasms: primary hepatic neoplasms, metastases to liver or peritoneum, lymphomas, leukemias, myeloid metaplasia.
Lymphatic obstruction: mediastinal tumors, trauma to the thoracic duct, filariasis.
Ovarian disease: Meigs syndrome, struma ovarii.
Chronic pancreatitis or pseudocyst: pancreatic ascites.
Leakage of bile: bile ascites.
Urinary obstruction or trauma: urine ascites.
Myxedema.
Chylous ascites.

ASPIRATION LUNG INJURY, CHILDREN[53]

ICD-10CM #	P24.8	Neonatal aspiration syndromes

CONDITIONS PREDISPOSING TO ASPIRATION LUNG INJURY IN CHILDREN

Anatomic and Mechanical

Tracheoesophageal fistula.
Laryngeal cleft.
Vascular ring.
Cleft palate.
Micrognathia.
Macroglossia.
Achalasia.
Esophageal foreign body.
Tracheostomy.
Endotracheal tube.
Nasoenteric tube.
Collagen vascular disease (scleroderma, dermatomyositis).
Gastroesophageal reflux disease.
Obesity.

Neuromuscular

Altered consciousness.
Immaturity of swallowing/prematurity.
Dysautonomia.
Increased intracranial pressure.
Hydrocephalus.
Vocal cord paralysis.
Cerebral palsy.
Muscular dystrophy.
Myasthenia gravis.
Guillain-Barré syndrome.
Werdnig-Hoffmann disease.
Ataxia-telangiectasia.
Cerebral vascular accident.

Miscellaneous

Poor oral hygiene.
Gingivitis.
Prolonged hospitalization.
Gastric outlet or intestinal obstruction.
Poor feeding techniques (bottle propping, overfeeding, inappropriate foods for toddlers).
Bronchopulmonary dysplasia.
Viral infection.

ASTHENIA

ICD-10CM #	G93.3	Postviral fatigue syndrome
	R53.1	Weakness
	R53.81	Other malaise
	R53.83	Other fatigue

Depression.
Chronic fatigue syndrome.
Sleep disorders.
Anemia.
Hypothyroidism.
Sedentary lifestyle.
Medications (e.g., narcotics, sedatives).
Infections.
Dehydration/electrolyte disorders.
COPD and other pulmonary disorders.
Renal failure.

CHF.
Diabetes.
Addison disease.
Paraneoplastic syndrome.

ASTHMA, CHILDHOOD[9]

ICD-10CM #		
	J45.20	Mild intermittent asthma, uncomplicated
	J45.22	Mild intermittent asthma with status asthmaticus

INFECTIONS

Bronchiolitis (RSV).
Pneumonia.
Croup.
Tuberculosis, histoplasmosis.
Bronchiectasis.
Bronchiolitis obliterans.
Bronchitis.
Sinusitis.

ANATOMIC, CONGENITAL

Cystic fibrosis.
Vascular rings.
Ciliary dyskinesia.
B-lymphocyte immune defect.
Congestive heart failure.
Laryngotracheomalacia.
Tumor, lymphoma.
H-type tracheoesophageal fistula.
Repaired tracheoesophageal fistula.
Gastroesophageal reflux.

VASCULITIS, HYPERSENSITIVITY

Allergic bronchopulmonary aspergillosis.
Allergic alveolitis, hypersensitivity pneumonitis.
Churg-Strauss syndrome.
Periarteritis nodosa.

OTHER

Foreign body aspiration.
Pulmonary thromboembolism.
Psychogenic cough.
Sarcoidosis.
Bronchopulmonary dysplasia.
Vocal cord dysfunction.

ATAXIA

ICD-10CM #		
	R27.0	Ataxia, unspecified
	R27.8	Other lack of coordination
	R27.9	Unspecified lack of coordination
	F10.229	Alcohol dependence with intoxication, unspecified
	F10.20	Alcohol dependence, uncomplicated
	G11.1	Early-onset cerebellar ataxia
	G31.89	Other specified degenerative diseases of nervous system
	F44.4	Conversion disorder with motor symptom or deficit
	F44.6	Conversion disorder with sensory symptom or deficit

Vertebral-basilar artery ischemia.
Diabetic neuropathy.
Tabes dorsalis.
Vitamin B_{12} deficiency.
Multiple sclerosis and other demyelinating diseases.
Meningomyelopathy.
Cerebellar neoplasms, hemorrhage, abscess, infarct.
Nutritional (Wernicke encephalopathy).
Paraneoplastic syndromes.
Parainfectious: Guillain-Barré syndrome, acute ataxia of childhood and young adults.
Toxins: phenytoin, alcohol, sedatives, organophosphates.
Wilson disease (hepatolenticular degeneration).
Hypothyroidism.
Myopathy.
Cerebellar and spinocerebellar degeneration: ataxia/telangiectasia, Friedreich ataxia.
Frontal lobe lesions: tumors, thrombosis of anterior cerebral artery, hydrocephalus.
Labyrinthine destruction: neoplasm, injury, inflammation, compression.
Hysteria.
AIDS.

ATAXIA, ACUTE OR RECURRENT[23]

ICD-10CM #		
	R27.0	Ataxia, unspecified
	R27.8	Other lack of coordination
	R27.9	Unspecified lack of coordination
	F10.229	Alcohol dependence with Intoxication, unspecified
	F10.20	Alcohol dependence, uncomplicated
	G11.1	Early-onset cerebellar ataxia
	G31.89	Other specified degenerative diseases of nervous system
	F44.4	Conversion disorder with motor symptom or deficit
	F44.6	Conversion disorder with sensory symptom or deficit

Drug ingestion (e.g., phenytoin, carbamazepine, sedatives, hypnotics, and phencyclidine) or intoxication (e.g., alcohol, ethylene glycol, hydrocarbon fumes, lead, mercury, or thallium).
Postinfectious (cerebellitis [e.g., varicella], acute disseminated encephalomyelitis).
Head trauma.
Basilar migraine.
Benign paroxysmal vertigo (migraine equivalent).
Brain tumor or neuroblastoma (if accompanied by opsoclonus or myoclonus [i.e., "dancing eyes, dancing feet"]).
Hydrocephalus.
Infection (e.g., labyrinthitis, abscess).
Seizure (ictal or postictal).
Vascular events (e.g., cerebellar hemorrhage or stroke).
Miller-Fisher variant of Guillain-Barré syndrome (ataxia, ophthalmoplegia, and areflexia). Warning: If bulbar signs present, disease is likely progressive; patient may lose ability to protect airway and/or ability to breathe.
Inherited ataxias.
Inborn errors of metabolism (e.g., mitochondrial disorders, amino-acidopathies, urea cycle defects).
Conversion reaction.
Multiple sclerosis.

ATAXIA, CEREBELLAR, ADULT ONSET[80]

ICD-10CM #		
	G11.0	Congenital nonprogressive ataxia
	G11.2	Late-onset cerebellar ataxia

CAUSES OF ADULT ONSET CEREBELLAR ATAXIA

Inherited
Later onset SCA syndromes.
Rarely Friedreich ataxia.
Congenital
Arnold–Chiari malformation (cerebellar ectopia).
Inflammatory
Multiple sclerosis.
Sarcoidosis.
Infections (TB, viral).
Neoplastic
Often metastatic in adults.
Meningioma, neurofibroma.
Hemangioblastoma.
Paraneoplastic
Usually with small cell bronchial carcinoma.
Vascular
Infarction, hemorrhage.
Arteriovenous malformations.
Trauma
Head injury.
Postsurgical.
Toxic
Alcohol, phenytoin, solvent abuse.
Endocrine
Hypothyroidism (very rare).
Degenerative
Multiple system atrophy (MSA).

ATAXIA, CEREBELLAR, CHILDREN[80]

ICD-10CM #		
	G11.0	Congenital nonprogressive ataxia
	G11.2	Late-onset cerebellar ataxia

CAUSES OF CEREBELLAR ATAXIA IN CHILDREN

Congenital Malformations
Cerebellar agenesis/hypoplasia.
Dandy–Walker syndrome.
Arnold–Chiari malformation.
Hereditary Ataxias
Friedreich ataxia.
Trauma
Birth trauma.
Head injury in childhood.
Infectious
Secondary to bacterial meningitis.
Secondary to encephalitis.
Hydrocephalus
Tumors
Medulloblastoma.
Astrocytoma.
Hemangioblastoma.

ATAXIA, CHRONIC OR PROGRESSIVE[23]

ICD-10CM #	R27.0	Ataxia, unspecified
	R27.8	Other lack of coordination
	R27.9	Unspecified lack of coordination
	G11.1	Early-onset cerebellar ataxia
	G11.0	Congenital nonprogressive ataxia
	G11.2	Late-onset cerebellar ataxia
	G11.3	Cerebellar ataxia with defective DNA repair
	G11.8	Other hereditary ataxia

Hydrocephalus.
Hypothyroidism.
Tumor or paraneoplastic syndrome.
Low vitamin E levels (e.g., cystic fibrosis).
Wilson disease.
Inborn errors of metabolism.
Inherited ataxias (e.g., ataxia-telangiectasia, Friedreich ataxia).

ATAXIA IN CHILDHOOD[89]

ICD-10CM #	G11.1	Early-onset cerebellar ataxia

SELECTED CAUSES OF ATAXIA IN CHILDHOOD

Congenital:
- Agenesis of vermis of the cerebellum.
- Aplasia or dysplasia of the cerebellum.
- Basilar impression.
- Cerebellar dysplasia with microgyria, macrogyria, or agyria.
- Cervical spinal bifida with herniation of the cerebellum (Chiari malformation, type 3).
- Chiari malformation.
- Dandy-Walker syndrome.
- Encephalocele.
- Hydrocephalus (progressive).
- Hypoplasia of the cerebellum.

Degenerative and/or genetic:
- Acute intermittent cerebellar ataxia.
- Ataxia, retinitis pigmentosa, deafness, vestibular abnormality, and intellectual deterioration.
- Ataxia-telangiectasia.
- Biemond posterior column ataxia.
- Cerebellar ataxia with deafness, anosmia, absent caloric responses, nonreactive pupils, and hyporeflexia.
- Cockayne syndrome.
- Dentate cerebellar ataxia (dyssynergia cerebellaris progressiva).
- Familial ataxia with macular degeneration.
- Friedreich ataxia.
- Hereditary cerebellar ataxia, intellectual retardation, choreoathetosis, and eunuchoidism.
- Hereditary cerebellar ataxia with myotonia and cataracts.
- Hypertrophic interstitial neuritis.
- Marie ataxia.
- Marinesco-Sjögren syndrome.
- Pelizaeus-Merzbacher disease.
- Periodic attacks of vertigo, diplopia, and ataxia—autosomal dominant inheritance.
- Posterior and lateral column difficulties, nystagmus, and muscle atrophy.
- Progressive cerebellar ataxia and epilepsy.
- Ramsay Hunt syndrome (myoclonic seizures and ataxia).
- Roussy-Lévy syndrome.
- Spinocerebellar ataxia (SCAs); olivopontocerebellar ataxias.

Endocrinologic:
- Cretinism.
- Hypothyroidism.

Infectious or postinfectious:
- Acute cerebellar ataxia.
- Acute disseminated encephalomyelitis.
- Cerebellar abscess.
- Coxsackievirus.
- Diphtheria.
- Echovirus.
- Fisher syndrome.
- Infectious mononucleosis (Epstein-Barr virus infection).
- Infectious polyneuropathy.
- Japanese B encephalitis.
- Mumps encephalitis.
- *Mycoplasma pneumoniae.*
- Pertussis.
- Polio.
- Postbacterial meningitis.
- Rubeola.
- Tuberculosis.
- Typhoid.
- Varicella.

Metabolic:
- Abetalipoproteinemia.
- Argininosuccinic aciduria.
- Ataxia with vitamin E deficiency (AVED).
- GM2 gangliosidosis (late).
- Hartnup disease.
- Hyperalaninemia.
- Hyperammonemia I and II.
- Hypoglycemia.
- Kearns-Sayre syndrome.
- Leigh disease.
- Maple syrup urine disease (intermittent).
- MERRF (Myoclonic epilepsy with ragged red fibers).
- Metachromatic leukodystrophy.
- Mitochondrial complex defects (I, III, IV).
- Multiple carboxylase deficiency (biotinidase deficiency).
- Neuronal ceroid-lipofuscinosis.
- Neuropathy, ataxia, retinitis pigmentosa (NARP).
- Niemann-Pick disease (late infantile).
- 5-Oxoprolinuria.
- Pyruvate decarboxylase deficiency.
- Refsum disease.
- Sialidosis.
- Triose-phosphate isomerase deficiency.
- Tryptophanuria.
- Wernicke encephalopathy (thiamine or B_1 deficiency).

Neoplastic:
- Frontal lobe tumors.
- Hemispheric cerebellar tumors.
- Midline cerebellar tumors.
- Neuroblastoma.
- Pontine tumors (primarily gliomas).
- Spinal cord tumors.

Primary psychogenic:
- Conversion reaction.

Toxic:
- Alcohol.
- Benzodiazepines.
- Carbamazepine.
- Clonazepam.
- Lead encephalopathy.
- Phenobarbital.
- Phenytoin.
- Primidone.
- Tick paralysis poisoning.

Traumatic:
- Acute cerebellar edema.
- Acute frontal lobe edema.

Vascular:
- Angioblastoma of cerebellum.
- Basilar migraine.
- Cerebellar embolism.
- Cerebellar hemorrhage.
- Cerebellar thrombosis.
- Posterior cerebellar artery disease.
- Vasculitis.
- von Hippel-Lindau disease.

ATAXIA, TOXIC CAUSES[84]

ICD-10CM #	R27.0	Early-onset cerebellar ataxia

SELECTED TOXIC CAUSES OF ATAXIA

Medications:
- Acetohexamide.
- Amiodarone.
- Anticholinergic agents.
- Antidepressants, including selective serotonin reuptake inhibitors.
- Antiepileptic drugs.
- Antihistamines.
- Antimicrobials, antifungals.
- Antineoplastics.

Antiparasitics.
Baclofen.
Buspirone.
Dextromethorphan.
Disulfiram.
Ethanol.
Fenfluramine.
Lithium.
Lysergic acid diethylamide (LSD), phencyclidine palmitate (PCP).
Mexiletine.
Sedatives, narcotics.
Industrial toxins:
Aluminum compounds.
Butyl alcohol.
Carbon monoxide.
Carbon tetrachloride.
Ethylene glycol.
Formaldehyde.
Gasoline.
Manganese.
Metaldehyde (snail bait, fire starters).
Paradichlorobenzene (moth repellent, diaper pail deodorant).
Rodenticides: aluminum phosphide, sodium monofluoroacetate.
Solvents.
Biologic toxins:
Belladonna, hyoscyamine.
Buckeye (*Aesculus* spp.).
Mayapple (*Podophyllum peltatum*).
Mescaline, peyote.
Podophyllum (ingested).
Poison hemlock (*Conium maculatum*).

ATELECTASIS

ICD-10CM #		
	J98.11	Atelectasis

Lung neoplasm (primary or metastatic).
Infection (pneumonia, TB, fungal, histoplasmosis).
Postoperative (lower lobes).
Sarcoidosis.
Mucoid impaction.
Foreign body.
Postinflammatory (middle lobe syndrome).
Pneumothorax.
Pleural effusion.
Pneumoconiosis.
Interstitial fibrosis.
Bulla.
Mediastinal or adjacent mass.

ATRIAL ENLARGEMENT, LEFT ATRIUM[36]

ICD-10CM #		
	I51.7	Cardiomegaly

CAUSES OF LARGE LEFT ATRIUM

Causes Due to Volume Overload
Mitral regurgitation (often with left ventricular failure).
Ventricular septal defect.
Patent ductus arteriosus.
Atrial septal defect with shunt reversal (i.e., pulmonary hypertension).
ASD with tricuspid atresia (obligatory shunt reversal).
Aortopulmonary window.
Causes Due to Pressure Overload
Mitral stenosis.
Noncompliant left ventricle: hypertension, hypertrophic cardiomyopathy, aortic stenosis.
Left ventricular failure (often with secondary mitral regurgitation).
Left atrial myxoma.
Other Causes (Both Rare)
Atrial fibrillation.
Isolated/idiopathic.

ATRIAL ENLARGEMENT, RIGHT ATRIUM

ICD-10CM #		
	I51.7	Cardiomegaly

Right ventricular failure.
Atrial septal defect.
Tricuspid regurgitation.
Tricuspid stenosis.
Pulmonary hypertension.
Restrictive cardiomyopathy.
Right atrial myxoma.
Ebstein anomaly.
Anomalous pulmonary venous drainage to the right atrium.
Endomyocardial fibrosis.
Sinus of Valsalva fistula.
Arrhythmogenic right ventricular dysplasia.

ATYPICAL LYMPHOCYTOSIS, HETEROPHIL NEGATIVE, INFECTIOUS CAUSES[3]

ICD-10CM #		
	D72.820	Lymphocytosis (symptomatic)

MOST COMMON INFECTIOUS CAUSES OF HETEROPHIL-NEGATIVE ATYPICAL LYMPHOCYTOSIS

Babesiosis.
Cytomegalovirus.
Epstein-Barr virus (particularly in children).
Human herpesvirus 6.
Human immunodeficiency virus (especially during acute seroconversion).
Infectious mononucleosis.
Malaria.
Measles.
Toxoplasmosis.
Varicella.
Infectious hepatitis.

AV NODAL BLOCK[33]

ICD-10CM #		
	I44.30	Unspecified atrioventricular block
	I44.2	Atrioventricular block, complete

Idiopathic fibrosis (Lenègre disease).
Sclerodegenerative processes (e.g., Lev disease with calcification of the mitral and aortic annuli).
AV node radiofrequency ablation procedure.
Medications (e.g., digoxin, beta-blockers, calcium channel blockers, class III antiarrhythmics).
Acute inferior wall MI.
Myocarditis.
Infections (endocarditis, Lyme disease).
Infiltrative diseases (e.g., hemochromatosis, sarcoidosis, amyloidosis).
Trauma (including cardiac surgical procedures).
Collagen vascular diseases.
Aortic root diseases (e.g., spondylitis).
Electrolyte abnormalities (e.g., hyperkalemia).

BACK PAIN

ICD-10CM #		
	M54.89	Other dorsalgia
	M54.9	Dorsalgia, unspecified
	M54.5	Low back pain
	F45.42	Pain disorder with related psychological factors
	M54.08	Panniculitis affecting regions of neck and back, sacral and sacrococcygeal region
	S23.9XXA	Sprain of unspecified parts of thorax, initial encounter
	M43.27	Fusion of spine, lumbosacral region
	M43.28	Fusion of spine, sacral and sacrococcygeal region
	M53.2X7	Spinal instabilities, lumbosacral region
	M53.3	Sacrococcygeal disorders, not elsewhere classified

Trauma: injury to bone, joint, or ligament.
Mechanical: pregnancy, obesity, fatigue, scoliosis.
Degenerative: osteoarthritis.
Infections: osteomyelitis, subarachnoid or spinal abscess, TB, meningitis, basilar pneumonia.
Metabolic: osteoporosis, osteomalacia.
Vascular: leaking aortic aneurysm, subarachnoid or spinal hemorrhage/infarction.
Neoplastic: myeloma, Hodgkin disease, carcinoma of pancreas, metastatic neoplasm from breast, prostate, lung.
GI: penetrating ulcer, pancreatitis, cholelithiasis, inflammatory bowel disease.
Renal: hydronephrosis, calculus, neoplasm, renal infarction, pyelonephritis.
Hematologic: sickle cell crisis, acute hemolysis.
Gynecologic: neoplasm of uterus or ovary, dysmenorrhea, salpingitis, uterine prolapse.
Inflammatory: ankylosing spondylitis, psoriatic arthritis, Reiter syndrome (reactive arthritis).
Lumbosacral strain.

Antiparasitics.
Baclofen.
Buspirone.
Dextromethorphan.
Disulfiram.
Ethanol.
Fenfluramine.
Lithium.
Lysergic acid diethylamide (LSD), phencyclidine palmitate (PCP).
Mexiletine.
Sedatives, narcotics.
Industrial toxins:
Aluminum compounds.
Butyl alcohol.
Carbon monoxide.
Carbon tetrachloride.
Ethylene glycol.
Formaldehyde.
Gasoline.
Manganese.
Metaldehyde (snail bait, fire starters).
Paradichlorobenzene (moth repellent, diaper pail deodorant).
Rodenticides: aluminum phosphide, sodium monofluoroacetate.
Solvents.
Biologic toxins:
Belladonna, hyoscyamine.
Buckeye (*Aesculus* spp.).
Mayapple (*Podophyllum peltatum*).
Mescaline, peyote.
Podophyllum (ingested).
Poison hemlock (*Conium maculatum*).

ATELECTASIS

ICD-10CM #		
	J98.11	Atelectasis

Lung neoplasm (primary or metastatic).
Infection (pneumonia, TB, fungal, histoplasmosis).
Postoperative (lower lobes).
Sarcoidosis.
Mucoid impaction.
Foreign body.
Postinflammatory (middle lobe syndrome).
Pneumothorax.
Pleural effusion.
Pneumoconiosis.
Interstitial fibrosis.
Bulla.
Mediastinal or adjacent mass.

ATRIAL ENLARGEMENT, LEFT ATRIUM[36]

ICD-10CM #		
	I51.7	Cardiomegaly

CAUSES OF LARGE LEFT ATRIUM

Causes Due to Volume Overload
Mitral regurgitation (often with left ventricular failure).
Ventricular septal defect.
Patent ductus arteriosus.
Atrial septal defect with shunt reversal (i.e., pulmonary hypertension).
ASD with tricuspid atresia (obligatory shunt reversal).
Aortopulmonary window.
Causes Due to Pressure Overload
Mitral stenosis.
Noncompliant left ventricle: hypertension, hypertrophic cardiomyopathy, aortic stenosis.
Left ventricular failure (often with secondary mitral regurgitation).
Left atrial myxoma.
Other Causes (Both Rare)
Atrial fibrillation.
Isolated/idiopathic.

ATRIAL ENLARGEMENT, RIGHT ATRIUM

ICD-10CM #		
	I51.7	Cardiomegaly

Right ventricular failure.
Atrial septal defect.
Tricuspid regurgitation.
Tricuspid stenosis.
Pulmonary hypertension.
Restrictive cardiomyopathy.
Right atrial myxoma.
Ebstein anomaly.
Anomalous pulmonary venous drainage to the right atrium.
Endomyocardial fibrosis.
Sinus of Valsalva fistula.
Arrhythmogenic right ventricular dysplasia.

ATYPICAL LYMPHOCYTOSIS, HETEROPHIL NEGATIVE, INFECTIOUS CAUSES[3]

ICD-10CM #		
	D72.820	Lymphocytosis (symptomatic)

MOST COMMON INFECTIOUS CAUSES OF HETEROPHIL-NEGATIVE ATYPICAL LYMPHOCYTOSIS

Babesiosis.
Cytomegalovirus.
Epstein-Barr virus (particularly in children).
Human herpesvirus 6.
Human immunodeficiency virus (especially during acute seroconversion).
Infectious mononucleosis.
Malaria.
Measles.
Toxoplasmosis.
Varicella.
Infectious hepatitis.

AV NODAL BLOCK[33]

ICD-10CM #		
	I44.30	Unspecified atrioventricular block
	I44.2	Atrioventricular block, complete

Idiopathic fibrosis (Lenègre disease).
Sclerodegenerative processes (e.g., Lev disease with calcification of the mitral and aortic annuli).
AV node radiofrequency ablation procedure.
Medications (e.g., digoxin, beta-blockers, calcium channel blockers, class III antiarrhythmics).
Acute inferior wall MI.
Myocarditis.
Infections (endocarditis, Lyme disease).
Infiltrative diseases (e.g., hemochromatosis, sarcoidosis, amyloidosis).
Trauma (including cardiac surgical procedures).
Collagen vascular diseases.
Aortic root diseases (e.g., spondylitis).
Electrolyte abnormalities (e.g., hyperkalemia).

BACK PAIN

ICD-10CM #		
	M54.89	Other dorsalgia
	M54.9	Dorsalgia, unspecified
	M54.5	Low back pain
	F45.42	Pain disorder with related psychological factors
	M54.08	Panniculitis affecting regions of neck and back, sacral and sacrococcygeal region
	S23.9XXA	Sprain of unspecified parts of thorax, initial encounter
	M43.27	Fusion of spine, lumbosacral region
	M43.28	Fusion of spine, sacral and sacrococcygeal region
	M53.2X7	Spinal instabilities, lumbosacral region
	M53.3	Sacrococcygeal disorders, not elsewhere classified

Trauma: injury to bone, joint, or ligament.
Mechanical: pregnancy, obesity, fatigue, scoliosis.
Degenerative: osteoarthritis.
Infections: osteomyelitis, subarachnoid or spinal abscess, TB, meningitis, basilar pneumonia.
Metabolic: osteoporosis, osteomalacia.
Vascular: leaking aortic aneurysm, subarachnoid or spinal hemorrhage/infarction.
Neoplastic: myeloma, Hodgkin disease, carcinoma of pancreas, metastatic neoplasm from breast, prostate, lung.
GI: penetrating ulcer, pancreatitis, cholelithiasis, inflammatory bowel disease.
Renal: hydronephrosis, calculus, neoplasm, renal infarction, pyelonephritis.
Hematologic: sickle cell crisis, acute hemolysis.
Gynecologic: neoplasm of uterus or ovary, dysmenorrhea, salpingitis, uterine prolapse.
Inflammatory: ankylosing spondylitis, psoriatic arthritis, Reiter syndrome (reactive arthritis).
Lumbosacral strain.

c0990 c0990

Psychogenic: malingering, hysteria, anxiety.
Endocrine: adrenal hemorrhage or infarction.

BACK PAIN, CHILDREN AND ADOLESCENTS[53]

ICD-10CM #		
	M54.5	Low back pain
	M54.9	Dorsalgia

INFLAMMATORY OR INFECTIOUS

Diskitis.
Vertebral osteomyelitis (pyogenic, tuberculous).
Spinal epidural abscess.
Pyelonephritis.
Pancreatitis.

RHEUMATOLOGIC

Pauciarticular juvenile rheumatoid arthritis.
Reiter syndrome (reactive arthritis).
Ankylosing spondylitis.
Psoriatic arthritis.

DEVELOPMENTAL

Spondylolysis.
Spondylolisthesis.
Scheuermann disease.
Scoliosis.

TRAUMATIC (ACUTE VERSUS REPETITIVE)

Hip-pelvis anomalies.
Herniated disk.
Overuse syndromes.
Vertebral stress fractures.
Upper cervical spine instability.

NEOPLASTIC

Vertebral Tumors
Benign
Eosinophilic granuloma.
Aneurysmal bone cyst.
Osteoid osteoma.
Osteoblastoma.
Malignant
Osteogenic sarcoma.
Leukemia.
Lymphoma.
Metastatic tumors.
Spinal Cord, Ganglia, and Nerve Roots
Intramedullary spinal cord tumor.
Sympathetic chain.
Ganglioneuroma.
Ganglioneuroblastoma.
Neuroblastoma.

OTHER

Intraabdominal or pelvic pathology.
Following lumbar puncture.
Conversion reaction.
Juvenile osteoporosis.

BACK PAIN, LOW, ACUTE[7]

ICD-10CM #		
	M54.5	Low back pain

DIFFERENTIAL CONSIDERATIONS IN ACUTE LOW BACK PAIN

Emergent
Aortic dissection.
Cauda equina syndrome.
Epidural abscess or hematoma.
Meningitis.
Ruptured/expanding aortic aneurysm.
Spinal fracture or subluxation with cord or root impingement.
Urgent
Back pain with neurologic deficits.
Disk herniation causing neurologic compromise.
Malignancy.
Sciatica with motor nerve root compression.
Spinal fractures without cord impingement.
Spinal stenosis.
Transverse myelitis.
Vertebral osteomyelitis.
Common or Stable
Acute ligamentous injury.
Acute muscle strain.
Ankylosing spondylitis.
Degenerative joint disease.
Intervertebral disk disease without impingement.
Pathologic fracture without impingement.
Seropositive arthritis.
Spondylolisthesis.
Referred or Visceral
Cholecystitis.
Esophageal disease.
Nephrolithiasis.
Ovarian torsion, mass, or tumor.
Pancreatitis.
Peptic ulcer disease.
Pleural effusion.
Pneumonia.
Pulmonary embolism.
Pyelonephritis.
Retroperitoneal hemorrhage or mass.

BACK PAIN, VISCEROGENIC ORIGIN

ICD-10CM #		
	F45.41	Pain disorder exclusively related to psychological factors
	M54	Dorsalgia
	M54.5	Low back pain

Urolithiasis.
Aortic aneurysm.
Colorectal carcinoma.
Endometriosis.
Tubal pregnancy.
Prostatitis.
Peptic ulcer.
Pancreatitis.
Diverticular spasm.
Metastatic neoplasm (e.g., bladder, uterus, ovary, kidney).

BACTERIAL OVERGROWTH, SMALL INTESTINE[86]

ICD-10CM #		
	A04.9	Bacterial Intestinal Infection, Unspecified

Gastric surgery—Billroth II.
Small bowel diverticula.
Small bowel stricture:
Crohn disease.
Radiation enteritis.
Impaired small intestinal motility:
Scleroderma.
Diabetes mellitus.
Chronic intestinal pseudoobstruction.
Miscellaneous/multifactorial:
Elderly.
Immune deficiency syndromes.
Chronic pancreatitis.
Cirrhosis.

BALLISM[7]

ICD-10CM #		
	G25.4	Drug-induced chorea
	G25.5	Other chorea

Cerebral infarction or hemorrhage.
Medications (e.g., dopamine agonists, phenytoin).
CNS neoplasm (primary or metastatic).
Nonketotic hyperosmolar state.

BILE DUCT, DILATED[86]

ICD-10CM #		
	K83.1	Obstruction of bile duct

Normal variant.
Post-cholecystectomy.
Unsuspected bile duct stone.
Sphincter of Oddi stenosis.
Occult bile duct stricture.
Previous bile duct injury.
Early carcinoma of the pancreas, carcinoma of the bile duct, or carcinoma of the ampulla.
Extrinsic compression of the bile duct by a primary or secondary neoplasm.

BILIARY OBSTRUCTION[74]

ICD-10CM #	Varies with specific diagnosis

CAUSES OF BILIARY OBSTRUCTION

Benign Miscellaneous
Choledocholithiasis.*
Hemobilia.*
Congenital biliary diseases.*
Caroli disease.*
Choledochal cysts.
Cholangitis.
Infectious.
Acute pyogenic cholangitis.*
Biliary parasites.*
Recurrent pyogenic cholangitis.*
HIV cholangiopathy.
Sclerosing cholangitis.
Neoplasms
Cholangiocarcinoma.
Gallbladder carcinoma.
Locally invasive tumors (esp. pancreatic adenocarcinoma).
Ampullary tumors.
Metastases.
Extrinsic compression
Mirizzi syndrome.
Pancreatitis.
Adenopathy.

*Denotes causes of painful jaundice.

BILIARY TREE, REFLUX OF GAS OR BOWEL[89]

ICD-10CM # Varies with specific diagnosis

CAUSES OF REFLUX OF GAS OR BOWEL CONTRAST INTO THE BILIARY TREE

Iatrogenic.
Sphincterotomy.
Choledochojejunostomy.
Gallstone fistula.
Cholecystoduodenal fistula.
Perforated ulcer.
Choledochoduodenal fistula.
Carcinoma.
Choledochoenteric fistula.

BLADDER (URINARY) WALL THICKENING[74]

ICD-10CM # Varies with specific diagnosis

CAUSES OF BLADDER WALL THICKENING

Focal
Neoplasm
Transitional cell carcinoma.
Squamous cell carcinoma.
Adenocarcinoma.
Lymphoma.
Metastases.
Infectious/Inflammatory.
Tuberculosis (acute).
Schistosomiasis (acute).
Cystitis.
Malakoplakia.
Cystitis cystica.
Cystitis glandularis.
Fistula.
Medical Diseases
Endometriosis.
Amyloidosis.
Trauma
Hematoma.
Diffuse
Neoplasm
Transitional cell carcinoma.
Squamous cell carcinoma.
Adenocarcinoma.
Infectious/Inflammatory
Cystitis.
Tuberculosis (chronic).
Schistosomiasis (chronic).
Medical Diseases
Interstitial cystitis.
Amyloidosis.
Neurogenic Bladder
Detrusor hyperreflexia.
Bladder Outlet Obstruction
With muscular hypertrophy.

BLEEDING, GI IN PATIENTS WITH AIDS[26]

ICD-10CM # K92.2 Gastrointestinal bleeding, unspecified

(EXCLUDING NON-AIDS-SPECIFIC DIAGNOSES)

Esophagus
Candida spp.*
Cytomegalovirus.*
HSV.
Idiopathic ulcer.
Stomach
Cytomegalovirus.*
Kaposi sarcoma.*
Cryptosporidiosis.
Lymphoma.
Small Intestine
Kaposi sarcoma.
Lymphoma.
Cytomegalovirus.
Salmonella spp.
Cryptosporidium.
Colon
Cytomegalovirus.*
Kaposi sarcoma.*
Entamoeba histolytica.
Campylobacter jejuni.
Clostridium difficile.
Shigella spp.
Idiopathic ulcerations.
Lymphoma.

*More frequent diagnosis.

BLEEDING, LOWER GI

ICD-10CM # K92.2 Gastrointestinal hemorrhage, unspecified

(ORIGINATING BELOW THE LIGAMENT OF TREITZ)

Small Intestine
Ischemic bowel disease (mesenteric thrombosis, embolism, vasculitis, trauma).
Small bowel neoplasm: leiomyomas, carcinoids.
Hereditary hemorrhagic telangiectasia (Rendu-Osler-Weber syndrome).
Meckel diverticulum and other small intestine diverticula.
Aortoenteric fistula.
Intestinal hemangiomas: blue rubber-bleb nevi, intestinal hemangiomas, cutaneous vascular nevi.
Hamartomatous polyps: Peutz-Jeghers syndrome (intestinal polyps, mucocutaneous pigmentation).
Infections of small bowel: tuberculous enteritis, enteritis necroticans.
Volvulus.
Intussusception.
Lymphoma of small bowel, sarcoma, Kaposi sarcoma.
Irradiation ileitis.
AV malformation of small intestine.
Inflammatory bowel disease.
Polyarteritis nodosa.
Other: pancreatoenteric fistulas, Henoch-Schönlein purpura, Ehlers-Danlos syndrome, SLE, amyloidosis, metastatic melanoma.
Colon
Carcinoma (particularly left colon).
Diverticular disease.
Inflammatory bowel disease.
Ischemic colitis.
Colonic polyps.
Vascular abnormalities: angiodysplasia, vascular ectasia.
Radiation colitis.
Infectious colitis.
Uremic colitis.
Aortoenteric fistula.
Lymphoma of large bowel.
Hemorrhoids.
Anal fissure.
Trauma, foreign body.
Solitary rectal/cecal ulcers.
Long-distance running.

BLEEDING, LOWER GI, PEDIATRIC[7]

ICD-10CM # K92.2 Gastrointestinal hemorrhage, unspecified

<3 MO

Swallowed maternal blood.
Infectious colitis.
Milk allergy.
Bleeding diathesis.
Intussusception.
Midgut volvulus.
Meckel diverticulum.
Necrotizing enterocolitis.

<2 YR

Anal fissure.
Infectious colitis.
Milk allergy.
Colitis.
Intussusception.
Meckel diverticulum.
Polyp.
Duplication.
Hemolytic-uremic syndrome.
Inflammatory bowel disease.
Pseudomembranous enterocolitis.

<5 YR

Infectious colitis.
Anal fissure.
Polyp.
Intussusception.
Meckel diverticulum.
Henoch-Schönlein purpura.
Hemolytic-uremic syndrome.
Inflammatory bowel disease.
Pseudomembranous enterocolitis.

5 TO 18 YR

Infectious colitis.
Inflammatory bowel disease.
Pseudomembranous enterocolitis.
Polyp.
Hemolytic-uremic syndrome.
Hemorrhoids.

BLEEDING, RECTAL[86]

ICD-10CM # K92.2 Gastrointestinal hemorrhage, unspecified

IN PATIENTS <40 YR

Very Common

Hemorrhoids.
Anal fissure.
Inflammatory bowel disease (mainly proctitis).

Less Common

Polyps (hamartomatous or adenomatous).
Infective colitis.
Meckel diverticulum.
Intussusception.

Rare

Colorectal cancer.

IN PATIENTS >40 YR

Hemorrhoids.
Anal fissure.
Colorectal cancer.
Colorectal polyps (mostly adenomas).
Angiodysplasia.
Diverticular disease.
Inflammatory bowel disease.
Ischemic colitis.
Infective colitis.

BLEEDING, THIRD TRIMESTER[1]

ICD-10CM #	N93.9	Abnormal uterine and vaginal bleeding, unspecified

Placental abruption.
Placenta previa.
Bloody show (extrusion of cervical mucus).
Vasa previa.
Disseminated intravascular coagulopathy.
Uterine rupture.
Cervicitis, cervical cancer, or other cervical abnormality.
Vaginal laceration.

BLEEDING, UPPER GI

ICD-10CM #	K92.2	Gastrointestinal hemorrhage, unspecified

(ORIGINATING ABOVE THE LIGAMENT OF TREITZ)

Swallowed Hemoptysis

Oral or pharyngeal lesions: swallowed blood from nose or oropharynx.
Esophageal: varices, ulceration, esophagitis, Mallory-Weiss tear, carcinoma, trauma.
Gastric: peptic ulcer (including Cushing and Curling ulcers), gastritis, angiodysplasia, gastric neoplasms, hiatal hernia, gastric diverticulum, pseudoxanthoma elasticum, Rendu-Osler-Weber syndrome.
Duodenal: peptic ulcer, duodenitis, angiodysplasia, aortoduodenal fistula, duodenal diverticulum, duodenal tumors, carcinoma of ampulla of Vater, parasites (e.g., hookworm), Crohn disease.
Biliary: hematobilia (e.g., penetrating injury to liver, hepatobiliary malignancy, endoscopic papillotomy).

BLEEDING, UPPER GI, PEDIATRIC[7]

ICD-10CM #	K92.2	Gastrointestinal hemorrhage, unspecified

<3 MO

Swallowed maternal blood.
Gastritis.
Ulcer, stress.
Bleeding diathesis.
Foreign body (NG tube).
Vascular malformation.
Duplication.

<2 YR

Esophagitis.
Gastritis.
Ulcer.
Pyloric stenosis.
Mallory-Weiss syndrome.
Vascular malformation.
Duplication.

<5 YR

Esophagitis.
Gastritis.
Ulcer.
Esophageal varices.
Foreign body.
Mallory-Weiss syndrome.
Hemophilia.
Vascular malformations.

5 TO 18 YR

Esophagitis.
Gastritis.
Ulcer.
Esophageal varices.
Mallory-Weiss syndrome.
Inflammatory bowel disease.
Hemophilia.
Vascular malformation.

BLEEDING, VAGINAL, NON-PREGNANT FEMALE[1]

ICD-10CM #	N93.9	Abnormal uterine and vaginal bleeding, unspecified

TRAUMA

Blunt force.
Penetrating force.
Foreign bodies.

INFECTIOUS

Vaginitis.
Cervicitis.
Endometritis.

DYSFUNCTIONAL UTERINE BLEEDING

Ovulatory.
Anovulatory.
Adenomyosis.

BENIGN GROWTHS

Uterine leiomyomas.
Cervical polyps.

MALIGNANCY

Vulvar.
Cervical.
Uterine.
Ovarian.

SYSTEMIC DISEASE

Medications

Anticoagulation (warfarin [Coumadin], low-molecular-weight heparin, clopidogrel [Plavix]).
Antipsychotics.
Corticosteroids.
Tamoxifen.
Selective serotonin reuptake inhibitors.
Contraceptives (oral, intrauterine devices, intramuscular).

BLINDNESS, GERIATRIC AGE

ICD-10CM #	H54.8	Legal blindness, as defined in USA

Cataracts.
Glaucoma.
Diabetic retinopathy.
Macular degeneration.
Trauma.
CVA.
Corneal scarring.
Giant cell arteritis.
Ocular herpes zoster.

BLINDNESS, MONOCULAR, TRANSIENT

ICD-10CM #	H54.41	Blindness, right eye, normal vision left eye
	H54.42	Blindness, left eye, normal vision right eye

Migraine (vasospasm).
Embolic cerebrovascular disease.
Intermittent angle-closure glaucoma.
Partial retinal vein occlusion.
Hyphema.
Optic disc edema.
Giant cell arteritis.
Psychogenic.
Hypotension.
Hypercoagulopathy disorders.
Multiple sclerosis.

BLINDNESS, PEDIATRIC AGE[55]

ICD-10CM #	H54.41	Blindness, right eye, normal vision left eye
	H54.42	Blindness, left eye, normal vision right eye

CONGENITAL
Optic nerve hypoplasia or aplasia.
Optic coloboma.
Congenital hydrocephalus.
Hydranencephaly.
Porencephaly.
Microencephaly.
Encephalocele, particularly occipital type.
Morning glory disc.
Aniridia.
Anterior microphthalmia.
Peter anomaly.
Persistent pupillary membrane.
Glaucoma.
Cataracts.
Persistent hyperplastic primary vitreous.

PHAKOMATOSES
Tuberous sclerosis.
Neurofibromatosis (special association with optic glioma).
Sturge-Weber syndrome.
von Hippel–Lindau disease.

TUMORS
Retinoblastoma.
Optic glioma.
Perioptic meningioma.
Craniopharyngioma.
Cerebral glioma.
Posterior and intraventricular tumors when complicated by hydrocephalus.
Pseudotumor cerebri.

NEURODEGENERATIVE DISEASES
Cerebral storage disease.
Gangliosidoses, particularly Tay-Sachs disease (infantile amaurotic familial idiocy), Sandhoff variant, generalized gangliosidosis.
Other lipidoses and ceroid lipofuscinoses, particularly the late-onset amaurotic familial idiocies such as those of Jansky-Bielschowsky and of Batten-Mayou-Spielmeyer-Vogt.
Mucopolysaccharidoses, particularly Hurler syndrome and Hunter syndrome.
Leukodystrophies (dysmyelination disorders), particularly metachromatic leukodystrophy and Canavan disease.
Demyelinating sclerosis (myelinoclastic diseases), especially Schilder disease and Devic neuromyelitis optica.
Special types: Dawson disease, Leigh disease, Bassen-Kornzweig syndrome, Refsum disease.
Retinal degenerations: retinitis pigmentosa and its variants, Leber congenital type.
Optic atrophies: congenital autosomal recessive type, infantile and congenital autosomal dominant types, Leber disease, and atrophies associated with hereditary ataxias—the types of Behr, of Marie, and of Sanger-Brown.

INFECTIOUS PROCESSES
Encephalitis, especially in the prenatal infection syndromes caused by *Toxoplasma gondii*, cytomegalovirus, rubella virus, *Treponema pallidum*, herpes simplex.
Meningitis, arachnoiditis.
Chorioretinitis.
Endophthalmitis.
Keratitis.

HEMATOLOGIC DISORDERS
Leukemia with CNS involvement.

VASCULAR AND CIRCULATORY DISORDERS
Collagen vascular diseases.
Arteriovenous malformations: intracerebral hemorrhage, subarachnoid hemorrhage.
Central retinal occlusion.

TRAUMA
Contusion or avulsion of optic nerves, chiasm, globe, cornea.
Cerebral contusion or laceration.
Intracerebral, subarachnoid, or subdural hemorrhage.

DRUGS AND TOXINS OTHER
Retinopathy of prematurity.
Sclerocornea.
Conversion reaction.
Optic neuritis.
Osteopetrosis.

BLISTERS, SUBEPIDERMAL

ICD-10CM #		
	T07	Unspecified multiple injuries

Burns.
Porphyria cutanea tarda.
Bullous pemphigoid.
Bullous drug reaction.
Arthropod bite reaction.
Toxic epidermal necrosis.
Dermatitis herpetiformis.
Polymorphous light eruption.
Variegate porphyria.
SLE.
Epidermolysis bullosa.
Pseudoporphyria.
Acute graft-versus-host reaction.
Linear IgA disease.
Leukocytoclastic vasculitis.
Pressure necrosis.
Urticaria pigmentosa.
Amyloidosis.

BONE AND/OR SOFT TISSUE HYPERTROPHY[71]

ICD-10CM #		
	M85.80	Other specified disorders of bone density and structure, unspecified site

DISORDERS ASSOCIATED WITH BONE AND/OR SOFT TISSUE HYPERTROPHY
Conditions Associated with Generalized Overgrowth
Pituitary gigantism and acromegaly.
Other endocrine disorders.
Cerebral gigantism (Sotos).
Conditions Associated with Limb Hemihypertrophy
Lipomatosis.
Idiopathic congenital hemihypertrophy (associated with tumors, e.g., Wilms tumor, adrenocortical tumors, hepatoblastoma).
Proteus syndrome (capillary port-wine hemangiomas, lymphangiomas, lipomas, epidermal nevi, hypertrophy hands and feet, macrocephaly).
Maffucci syndrome (enchondromas, exostosis, lymphangiomas, venous angiomas).
Klippel-Trenaunay syndrome (capillary port-wine hemangiomas, varicosities, lymphangiomas).
Parkes Weber syndrome (capillary port-wine hemangiomas, varicosities, arteriovenous fistula).
Blue rubber bleb nevus syndrome (cavernous hemangiomas of skin, GI tract).
Other angiodysplasias (e.g., Servelle-Martorell syndrome; venous arterial malformations with limb hypertrophy and bony hypoplasia).
Beckwith-Wiedemann syndrome (macroglossia, visceromegaly, omphaloceles, hemihypertrophy, etc.).
Conditions Associated with Macrodactyly
Neurofibromatosis.
Macrodystrophia lipomatosa.
Proteus syndrome.
Bannayan-Zonana syndrome (lipomatosis, angiomatosis, macrocephaly).
Hemangiomatosis and other vascular malformations (Klippel-Trenaunay and Parkes Weber).
Lymphangiomatosis.
Arteriovenous malformation.
Maffucci syndrome, Ollier disease.
Epidermal nevus syndrome.

BONE DENSITY, DECREASED, GENERALIZED[36]

ICD-10CM #		
	M85.80	Other specified disorders of bone density and structure, unspecified site

DISORDERS ASSOCIATED WITH GENERALIZED LOSS OF BONE DENSITY
Disorders of Multiple or Uncertain Cause
Senile osteoporosis.[8]
Juvenile osteoporosis.
Osteogenesis imperfecta.[9]
Secondary Bone Disorders
Endocrine
Adrenal cortex:
Cushing disease.
Addison disease.
Gonadal disorders:
Postmenopausal osteoporosis.
Hypogonadism.
Pituitary:

[8] Patients who cannot synthesize Lewis blood group antigens (~5% of the population) do not produce CA–19–9 antigen.
[9] Common cause of decrease in bone density in children.

Acromegaly.
Hypopituitarism.
Pancreas:
Diabetes mellitus.
Thyroid:
Hyperthyroidism.
Hypothyroidism.
Parathyroid:
Hyperparathyroidism.
Marrow Replacement and Expansion
Myeloma.
Leukemia.
Lymphoma.
Metastatic disease.
Gaucher disease.
Anemias (sickle cell, thalassemia, hemophilia).
Drugs and Other Substances
Steroids.
Heparin (osteoporosis).
Anticonvulsants (osteomalacia).
Immunosuppressants.
Alcohol.
Chronic Disease
Chronic renal disease.
Hepatic insufficiency.
GI malabsorption syndromes.
Chronic inflammatory polyarthropathies.
Chronic debility or immobilization.

*Common cause of decrease in bone density in adults.

BONE DENSITY, DECREASED, LOCALIZED[36]

ICD-10CM #		
	Z82.62	Family history of osteoporosis
	M85.80	Other specified disorders of bone density and structure, unspecified site

DISORDERS ASSOCIATED WITH LOCALIZED LOSS OF BONE DENSITY

Disuse osteoporosis.[10]
Reflex sympathetic dystrophy (Sudeck).
Osteolytic syndromes:
Acro-osteolysis, primary and secondary.
Massive osteolysis of Gorham.
Carpotarsal osteolysis.
Transient regional osteoporosis.
Neuromuscular disorders.
Infection.
Arthropathies.
Tumors, primary and secondary, myelomatosis.

[10] Common causes.

BONE LESIONS, PREFERENTIAL SITE OF ORIGIN[81]

ICD-10CM #		
	C41.0	Malignant neoplasm of bones of skull and face
	C41.1	Malignant neoplasm of mandible
	C41.2	Malignant neoplasm of vertebral column
	C41.3	Malignant neoplasm of ribs, sternum and clavicle
	C40.00	Malignant neoplasm of scapula and long bones of unspecified upper limb
	C40.10	Malignant neoplasm of short bones of unspecified upper limb
	C41.4	Malignant neoplasm of pelvic bones, sacrum and coccyx
	C40.20	Malignant neoplasm of long bones of unspecified lower limb
	C40.30	Malignant neoplasm of short bones of unspecified lower limb
	C41.9	Malignant neoplasm of bone and articular cartilage, unspecified
	C79.51	Secondary malignant neoplasm of bone
	C79.52	Secondary malignant neoplasm of bone marrow

EPIPHYSIS

Chondroblastoma.
Giant cell tumor—after fusion of growth plate.
Langerhans cell histiocytosis.
Clear cell chondrosarcoma.
Osteosarcoma.

METAPHYSIS

Parosteal sarcoma.
Chondrosarcoma.
Fibrosarcoma.
Nonossifying fibroma.
Giant cell tumor—before fusion of growth plate.
Unicameral bone cyst.
Aneurysmal bone cyst.

DIAPHYSIS

Myeloma.
Ewing tumor.
Reticulum cell sarcoma.

METADIAPHYSEAL

Fibrosarcoma.
Fibrous dysplasia.
Enchondroma.
Osteoid osteoma.
Chondromyofibroma.

BONE MARROW FAILURE SYNDROMES, INHERITED[45]

ICD-10CM #		
	D61.89	Other specified aplastic anemias and other bone marrow failure syndromes

BI-LINEAGE AND TRI-LINEAGE CYTOPENIAS

Fanconi anemia.
Shwachman-Diamond syndrome.
Dyskeratosis congenita.
Amegakaryocytic thrombocytopenia:
Other inherited thrombocytopenia disorders.
Other genetic syndromes:
Down syndrome.
Dubowitz syndrome.
Seckel syndrome.
Reticular dysgenesis.
Schimke immunoosseous dysplasia.
Noonan syndrome.
Cartilage-hair hypoplasia.
Familial marrow failure (non-Fanconi).

UNI-LINEAGE CYTOPENIA

Diamond-Blackfan anemia.
Kostmann syndrome/Congenital neutropenia:
ELA2 mutations.
HAX1 mutations.
GFI1 mutations.
WASP mutations.
Constitutive cell surface G-CSF-R mutations.
Other inherited neutropenia syndromes:
Barth syndrome.
Glycogen storage disease 1b.
Miscellaneous.
Thrombocytopenia with absent radii.
Congenital dyserythropoietic anemias (CDAs):
Types I, II, III, IV.
Variants.
Nonclassifiable CDAs.
Groups IV, V, VI, VII.

BONE MARROW FIBROSIS[32]

ICD-10CM #		
	D75.9	Disease of blood and blood-forming organs, unspecified

MYELOID DISORDERS

Myelofibrosis with myeloid metaplasia.
Metastatic cancer.
Chronic myeloid leukemia.
Myelodysplastic syndrome.
Atypical myeloid disorder.
Acute megakaryocytic leukemia.
Other acute myeloid leukemias.
Gray platelet syndrome.

LYMPHOID DISORDERS

Hairy cell leukemia.
Multiple myeloma.
Lymphoma.

NONHEMATOLOGIC DISORDERS

Connective tissue disorder.
Infections (tuberculosis, kala-azar).
Vitamin D deficiency (rickets).
Renal osteodystrophy.

BONE MASS, LOW[3]

ICD-10CM #		
	M85.80	Other specified disorders of bone density and structure, unspecified site

SECONDARY CAUSES OF LOW BONE MASS

Endocrine Diseases
Female hypogonadism.
Hyperprolactinemia.
Hypothalamic amenorrhea.
Anorexia nervosa.
Premature and primary ovarian failure.
Female athlete triad.
Male hypogonadism.
Primary gonadal failure (e.g., Klinefelter syndrome).
Secondary gonadal failure (e.g., idiopathic hypogonadotropic hypogonadism, androgen deprivation therapy for prostate cancer).
Hyperthyroidism.
Hyperparathyroidism.
Hypercortisolism.
Vitamin D insufficiency or deficiency.
Gastrointestinal Diseases
Subtotal gastrectomy.
Gastric bypass surgery.
Malabsorption syndromes.
Chronic obstructive jaundice.
Primary biliary cirrhosis and other cirrhoses.
Bone Marrow Disorders
Multiple myeloma.
Monoclonal gammopathy of unknown significance (MGUS).
Lymphoma.
Leukemia.
Hemolytic anemias.
Systemic mastocytosis.
Disseminated carcinoma.
Connective Tissue Diseases
Osteogenesis imperfecta.
Ehlers-Danlos syndrome.
Marfan syndrome.
Homocystinuria.
Drugs
Alcohol.
Antiseizure medications.
Aromatase inhibitors.
Chemotherapy.
Cyclosporine.
Depo-medroxyprogesterone.
Excess thyroid hormone.
Glucocorticoids.
Gonadotropin-releasing hormone agonists.
Heparin.
Miscellaneous Causes
Immobilization.
Rheumatoid arthritis.
Chronic obstructive pulmonary disease.
Weight loss.

BONE MINERAL DENSITY, INCREASED

ICD-10CM #		
	M89.30	Hypertrophy of bone, unspecified site
	M89.8X9	Other specified disorders of bone, unspecified site
	M94.8X9	Other specified disorders of cartilage, unspecified sites

Paget disease of bone.
Skeletal metastases.
DISH.
Osteonecrosis.
Sarcoidosis.
Hypoparathyroidism, pseudohypoparathyroidism.
Milk-alkali syndrome.
Osteopetrosis.
Hypervitaminosis A or D.
Dysplasias (craniodiaphyseal, craniometaphyseal, frontometaphyseal).
Endosteal hyperostosis.
Fluorosis.
Heavy metal poisoning.
Ionizing radiation.
Other: lymphoma, leukemia, mastocytosis, multiple myeloma, polycythemia vera.

BONE PAIN

ICD-10CM #		
	M89.8	Pain, bone

Trauma.
Neoplasm (primary or metastatic).
Osteoporosis with compression fracture.
Paget disease of bone.
Infection (osteomyelitis, septic arthritis).
Osteomalacia.
Viral syndrome.
Sickle cell disease.
Anxiety.

BONE RESORPTION[81]

ICD-10CM #		
	M89.9	Disorder of bone, unspecified
	M94.9	Disorder of cartilage, unspecified

DISTAL CLAVICLE

Hyperparathyroidism.
RA.
Scleroderma.
Posttraumatic osteolysis.
Progeria.
Pycnodysostosis.
Cleidocranial dysplasia.

INFERIOR ASPECT OF RIBS

Vascular impression associated with but not limited to coarctation of the aorta.
Hyperparathyroidism.
Neurofibromatosis.

TERMINAL PHALANGEAL TUFTS

Scleroderma.
Raynaud phenomenon.
Vascular disease.
Frostbite, electrical burns.
Psoriasis.
Tabes dorsalis.
Hyperparathyroidism.

GENERALIZED RESORPTION

Paraplegia.
Myositis ossificans.
Osteoporosis.

BOWEL WALL THICKENING[89]

ICD-10CM #	Varies with specific diagnosis

BENIGN VERSUS MALIGNANT BOWEL WALL THICKENING

Benign
Homogeneous attenuation.
Symmetrical.
Circumferential.
Thickening <1 cm.
Segmental or diffuse involvement.
Double halo sign.
Dark inner ring.
Bright outer ring.
Target sign.
Bright inner ring.
Dark middle ring.
Bright outer ring.
Malignant
Heterogeneous attenuation.
Asymmetrical.
Eccentric.
Thickening >1 to 2 cm.
Focal mass.
Abrupt transition.
Lobulated contour.
Spiculated contour.
Narrowed bowel lumen.
Enlarged lymph nodes.
Liver metastases.

BOW LEGS (GENU VARUM), CLASSIFICATION[53]

ICD-10CM #		
	E64.3	Genu varum, acquired
	Q74.1	Congenital malformation of knee

PHYSIOLOGIC

Asymmetric Growth
Tibia vara (Blount disease):
Infantile.
Juvenile.
Adolescent.
Focal fibrocartilaginous dysplasia.
Physeal injury.
Trauma.
Infection.
Tumor.

METABOLIC DISORDERS

Vitamin D deficiency (nutritional rickets).
Vitamin D–resistant rickets.
Hypophosphatasia.

SKELETAL DYSPLASIA

Metaphyseal dysplasia.

Achondroplasia.
Enchondromatosis.

BRACHYCARDIA, ICU PATIENT[38]

ICD-10CM #	R00.1	Bradycardia, unspecified

COMMON CAUSES OF BRADYCARDIA IN THE ICU

Medications: antiarrhythmics, β-blockers, calcium channel blockers, clonidine, dexmedetomidine, digoxin, lithium, opioids, phenytoin, and propofol.
Age-related degeneration.
Cardiac ischemia.
Electrolyte abnormalities.
Elevated intracranial pressure.
Elevated vagal tone.
Endotracheal intubation.
Hypertension.
Hypothermia.
Hypothyroidism.
Hypoxia.
Inflammatory disease.
Obstructive sleep apnea.
Post-cardiac surgery.

BRADYCARDIA, SINUS[33]

ICD-10CM #	I49.8	Other specified cardiac arrhythmias
	R00.1	Bradycardia, unspecified

Idiopathic.
Degenerative processes (e.g., Lev disease, Lenègre disease).
Medications
β-Blockers.
Some calcium channel blockers (diltiazem, verapamil).
Digoxin (when vagal tone is high).
Class I antiarrhythmic agents (e.g., procainamide).
Class III antiarrhythmic agents (amiodarone, sotalol).
Clonidine.
Lithium carbonate.

ACUTE MYOCARDIAL ISCHEMIA AND INFARCTION

Right or left circumflex coronary artery occlusion or spasm.
High vagal tone (e.g., athletes).

BRAIN MASS[1]

ICD-10CM #	C71	Malignant neoplasm of brain
	D33	Benign neoplasm of brain
	I61.9	Intracranial hemorrhage, unspecified

METASTATIC BRAIN TUMOR

Primary Brain Tumor
Meningioma.
Glioma.
Pituitary adenoma.
Vestibular schwannoma.
Primary or secondary CNS lymphoma.
Infections
Abscess.
Toxoplasmosis.
Neurocysticercosis.
Tuberculoma.
Progressive multifocal leukoencephalopathy.

VASCULAR DISEASE

Hemorrhage
Anomalies (arteriovenous malformation).
Intratumoral.
Hypertensive.
Infarct
Embolism.
Thrombosis (sinus venous).
Inflammatory
Multiple sclerosis.
Encephalomyelitis.

BREAST INFLAMMATORY LESION[24]

ICD-10CM #	N61	Inflammatory disorders of breast
	N60.19	Diffuse cystic mastopathy of unspecified breast
	P39.0	Neonatal infective mastitis
	P83.4	Breast engorgement of newborn

Mastitis (*S. aureus*, β-hemolytic *Streptococcus*).
Trauma.
Foreign body (sutures, breast implants).
Granuloma (TB, fungal).
Fat necrosis post biopsy.
Necrosis or infarction (anticoagulant therapy, pregnancy).
Breast malignancy.

BREAST MASS

ICD-10CM #	N63	Unspecified lump in breast

Fibrocystic breasts.
Benign tumors (fibroadenoma, papilloma).
Mastitis (acute bacterial mastitis, chronic mastitis).
Malignant neoplasm.
Fat necrosis.
Hematoma.
Duct ectasia.
Mammary adenosis.

BREATH ODOR[78]

ICD-10CM #	R19.6	Halitosis

Sweet, fruity: DKA, starvation ketosis.
Fishy, stale: uremia (trimethylamines).
Ammonia-like: uremia (ammonia).
Musty fish, clover: fetor hepaticus (hepatic failure).
Foul, feculent: intestinal obstruction/diverticulum.
Foul, putrid: nasal/sinus pathology (infection, foreign body, cancer), respiratory infections (empyema, lung abscess, bronchiectasis).
Halitosis: tonsillitis, gingivitis, respiratory infections, Vincent angina, gastroesophageal reflux, achalasia, certain foods (garlic, onions, protein drinks, etc.)
Cinnamon: pulmonary TB.

BREATHING, NOISY[78]

ICD-10CM #	R06.00	Dyspnea, unspecified
	R06.09	Other forms of dyspnea
	R06.3	Periodic breathing
	R06.83	Snoring
	R06.89	Other abnormalities of breathing
	R06.1	Stridor

Infection: upper respiratory infection, peritonsillar abscess, retropharyngeal abscess, epiglottitis, laryngitis, tracheitis, bronchitis, bronchiolitis.
Irritants and allergens: hyperactive airway, asthma (reactive airway disease), rhinitis, angioneurotic edema.
Compression from outside of the airway: esophageal cysts or foreign body, neoplasms, lymphadenopathy.
Congenital malformation and abnormality: vascular rings, laryngeal webs, laryngomalacia, tracheomalacia, hemangiomas within the upper airway, stenoses within the upper airway, cystic fibrosis.
Acquired abnormality (at every level of the airway): nasal polyps, hypertrophied adenoids and/or tonsils, foreign body, intraluminal tumors, bronchiectasis.
Neurogenic disorder: vocal cord paralysis.

BRONCHIAL OBSTRUCTION[36]

ICD-10CM #	J98.0	Tracheobronchial collapse

CAUSES OF BRONCHIAL OBSTRUCTION

Outside the Bronchus
Lymph nodes and other masses.
In the Wall of the Bronchus
Tumors
Lung carcinoma (commonly squamous cell).
Bronchial carcinoid.
Metastasis.
Hamartoma.
Inflammation
Tuberculosis.
Sarcoidosis.
Granulomatosis with polyangiitis.
Inflammatory bowel disease.
Bronchomalacia
Broncholith.
Inside the Bronchus
Mucus plug.
Inhaled foreign body.

BRONCHOPLEURAL FISTULA[36]

ICD-10CM #		
	J86.0	Bronchopleural fistula

CAUSES OF BRONCHOPLEURAL FISTULA

Trauma
Penetrating.
Iatrogenic (especially post-pneumonectomy, post-lobectomy, post-biopsy).
Infection
Necrotizing pneumonia.
Empyema.
Tuberculosis.
Septic embolus.
Infected pulmonary infarct.

BROWN URINE

ICD-10CM #		
	R82	Other abnormal findings in urine

Bile pigments.
Myoglobin.
Concentrated urine.
Use of multivitamin supplements.
Medications (antimalarials, metronidazole, nitrofurantoin, levodopa, methyldopa, phenazopyridine).
Diet rich in fava beans.
Urinary tract infection.

BRUISING

ICD-10CM #		
	I99.8	Other disorder of circulatory system

Medication-induced (warfarin, aspirin, NSAIDs, prednisone).
Alcohol abuse.
Senile purpura.
Purpura simplex.
Physical abuse.
Vasculitis.
Platelet disorders.
Coagulation factor deficiencies.
Cushing disease.
Vitamin C deficiency.
Marfan syndrome.
Ehlers-Danlos syndrome.
Disseminated intravascular coagulation.
Leukemia.
Hereditary hemorrhagic telangiectasia.

BULLOUS DISEASES

ICD-10CM #		
	L13.9	Bullous disorder, unspecified
	L12.0	Bullous pemphigoid
	L12.8	Other pemphigoid
	L10.0	Pemphigus vulgaris
	L10.1	Pemphigus vegetans
	L10.2	Pemphigus foliaceous
	L10.4	Pemphigus erythematosus
	L10.9	Pemphigus, unspecified

Bullous pemphigoid.
Pemphigus vulgaris.
Pemphigus foliaceus.
Paraneoplastic pemphigus.
Cicatricial pemphigoid.
Erythema multiforme.
Dermatitis herpetiformis.
Herpes gestationis.
Impetigo.
Erosive lichen planus.
Linear IgA bullous dermatosis.
Epidermolysis bullosa acquisita.

CAFÉ-AU-LAIT SPOTS[53]

ICD-10CM #		
	L81.3	Cafe au lait spots

Neurofibromatosis types 1 and 2.
McCune-Albright syndrome.
Russell-Silver syndrome.
Ataxia-telangiectasia.
Fanconi anemia.
Tuberous sclerosis.
Bloom syndrome.
Basal cell nevus syndrome.
Gaucher disease.
Chédiak-Higashi syndrome.
Hunter syndrome.
Maffucci syndrome.
Multiple mucosal neuroma syndrome.
Watson syndrome.
Proteus syndrome.
Turner syndrome.
Ring chromosome syndrome.
Jaffe-Campanacci syndrome.

CALCIFICATION ON CHEST X-RAY

ICD-10CM #		
	J98.4	Calcification of lung
	M51.84	Other intervertebral disc disorders, thoracic region
	M51.85	Other intervertebral disc disorders, thoracolumbar region

Lung neoplasm (primary or metastatic).
Silicosis.
Idiopathic pulmonary fibrosis.
Tuberculosis.
Histoplasmosis.
Disseminated varicella infection.
Mitral stenosis (end-stage).
Secondary hyperparathyroidism.

CALCIFICATIONS, ABDOMINAL, NONVISCERAL ON X-RAY[36]

ICD-10CM #		
	M61.9	Calcification and ossification of muscle, unspecified

NONVISCERAL ABDOMINAL CALCIFICATION

Common
Atherosclerosis.
Mesenteric lymph nodes.
Phleboliths.
Aneurysm.
Dermoid cyst.
Differentiate
Rib cartilage.
Injections in the buttocks.
Uncommon
Infestations:
Armillifer armillatus.
Cysticercosis.
Guinea worm.
Hydatid.
Tumors:
Lipoma.
Hemangioma.
Neuroblastoma.
Osteo/chondrosarcoma of soft tissues.
Retroperitoneal sarcoma of soft tissues.
Peritoneal metastases.
Pheochromocytoma.
Tuberculosis:
Peritonitis.
Psoas abscess.
Meconium peritonitis.
Pseudomyxoma Peritonei
Mesenteric cyst.
Pancreatitis with saponification.
Lithopedion.
Appendices Epiploicae
Ligaments.
Foreign bodies.
Posttraumatic buttock cysts.

CALCIFICATIONS, ADRENAL GLAND ON X-RAY[36]

ICD-10CM #		
	E27.4	Calcification, adrenal gland

ADRENAL GLAND CALCIFICATION

Common
Idiopathic.
Hemorrhage.
Tuberculosis.
Neuroblastoma/ganglioneuroma.
Pheochromocytoma.
Uncommon
Other tumors:
Adenoma.
Carcinoma.
Dermoid.
Addison disease.
Cyst.
Histoplasmosis.

CALCIFICATIONS, CARDIAC ON X-RAY[36]

ICD-10CM #		
	I51.5	Calcification, myocardium
	I25.1	Calcification, arteriosclerotic

CAUSES OF VISIBLE CALCIFICATION WITHIN THE HEART

Coronary Artery
Atherosclerosis.

BRONCHOPLEURAL FISTULA[36]

ICD-10CM #		
	J86.0	Bronchopleural fistula

CAUSES OF BRONCHOPLEURAL FISTULA

Trauma
Penetrating.
Iatrogenic (especially post-pneumonectomy, post-lobectomy, post-biopsy).
Infection
Necrotizing pneumonia.
Empyema.
Tuberculosis.
Septic embolus.
Infected pulmonary infarct.

BROWN URINE

ICD-10CM #		
	R82	Other abnormal findings in urine

Bile pigments.
Myoglobin.
Concentrated urine.
Use of multivitamin supplements.
Medications (antimalarials, metronidazole, nitrofurantoin, levodopa, methyldopa, phenazopyridine).
Diet rich in fava beans.
Urinary tract infection.

BRUISING

ICD-10CM #		
	I99.8	Other disorder of circulatory system

Medication-induced (warfarin, aspirin, NSAIDs, prednisone).
Alcohol abuse.
Senile purpura.
Purpura simplex.
Physical abuse.
Vasculitis.
Platelet disorders.
Coagulation factor deficiencies.
Cushing disease.
Vitamin C deficiency.
Marfan syndrome.
Ehlers-Danlos syndrome.
Disseminated intravascular coagulation.
Leukemia.
Hereditary hemorrhagic telangiectasia.

BULLOUS DISEASES

ICD-10CM #		
	L13.9	Bullous disorder, unspecified
	L12.0	Bullous pemphigoid
	L12.8	Other pemphigoid
	L10.0	Pemphigus vulgaris
	L10.1	Pemphigus vegetans
	L10.2	Pemphigus foliaceous
	L10.4	Pemphigus erythematosus
	L10.9	Pemphigus, unspecified

Bullous pemphigoid.
Pemphigus vulgaris.
Pemphigus foliaceus.
Paraneoplastic pemphigus.
Cicatricial pemphigoid.
Erythema multiforme.
Dermatitis herpetiformis.
Herpes gestationis.
Impetigo.
Erosive lichen planus.
Linear IgA bullous dermatosis.
Epidermolysis bullosa acquisita.

CAFÉ-AU-LAIT SPOTS[53]

ICD-10CM #		
	L81.3	Cafe au lait spots

Neurofibromatosis types 1 and 2.
McCune-Albright syndrome.
Russell-Silver syndrome.
Ataxia-telangiectasia.
Fanconi anemia.
Tuberous sclerosis.
Bloom syndrome.
Basal cell nevus syndrome.
Gaucher disease.
Chédiak-Higashi syndrome.
Hunter syndrome.
Maffucci syndrome.
Multiple mucosal neuroma syndrome.
Watson syndrome.
Proteus syndrome.
Turner syndrome.
Ring chromosome syndrome.
Jaffe-Campanacci syndrome.

	M61.9	Calcification and ossification of muscle, unspecified

NONVISCERAL ABDOMINAL CALCIFICATION

Common
Atherosclerosis.
Mesenteric lymph nodes.
Phleboliths.
Aneurysm.
Dermoid cyst.
Differentiate
Rib cartilage.
Injections in the buttocks.
Uncommon
Infestations:
Armillifer armillatus.
Cysticercosis.
Guinea worm.
Hydatid.
Tumors:
Lipoma.
Hemangioma.
Neuroblastoma.
Osteo/chondrosarcoma of soft tissues.
Retroperitoneal sarcoma of soft tissues.
Peritoneal metastases.
Pheochromocytoma.
Tuberculosis:
Peritonitis.
Psoas abscess.
Meconium peritonitis.
Pseudomyxoma Peritonei
Mesenteric cyst.
Pancreatitis with saponification.
Lithopedion.
Appendices Epiploicae
Ligaments.
Foreign bodies.
Posttraumatic buttock cysts.

CALCIFICATIONS, ADRENAL GLAND ON X-RAY[36]

ICD-10CM #		
	E27.4	Calcification, adrenal gland

ADRENAL GLAND CALCIFICATION

Common
Idiopathic.
Hemorrhage.
Tuberculosis.
Neuroblastoma/ganglioneuroma.
Pheochromocytoma.
Uncommon
Other tumors:
Adenoma.
Carcinoma.
Dermoid.
Addison disease.
Cyst.
Histoplasmosis.

CALCIFICATIONS, CARDIAC ON X-RAY[36]

ICD-10CM #		
	I51.5	Calcification, myocardium
	I25.1	Calcification, arteriosclerotic

CAUSES OF VISIBLE CALCIFICATION WITHIN THE HEART

Coronary Artery
Atherosclerosis.

c0991 c0991

Aortic Root
Atherosclerotic aorta.
Thrombus.
Syphilis.
Ankylosing spondylitis.
Homograft calcification.
Pericardium
Chronic pericarditis, tuberculosis, hemopericardium, pyogenic or viral pericarditis.
Posttraumatic.
Postoperative.
Uremic pericarditis.
Asbestosis (may be pleural calcification applied to pericardium).
Myocardium
Ventricular aneurysm (may mimic pericardial calcification).
Calcified myocardial infarction.
Postmyocarditis.
Endocardium
Endomyocardial fibrosis.
Thrombus.
Valve Cusps
Calcified valves (particularly mitral and aortic valves).
Mitral annulus calcification.
Homograft calcification.
Old vegetation.
Valve Annulus
Submitral.
Mitral.
Aortic.
Left Atrium
Wall.
Thrombus.
Atrial myxoma.
Pulmonary Artery
Pulmonary hypertension.
Postoperative:
Postoperative serumoma calcified hydatid cyst.

CALCIFICATIONS, CUTANEOUS

ICD-10CM #	L94.2	Calcinosis cutis
	L98.8	Other specified disorders of the skin and subcutaneous tissue

Calcification, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasia (CREST) syndrome.
Trauma.
Pancreatitis or pancreatic cancer.
Chronic renal failure.
Sarcoidosis.
Hyperparathyroidism.
Milk-alkali syndrome.
Hypervitaminosis D.
Panniculitis.
Idiopathic.
Iatrogenic (e.g., application of calcium alginate dressing to skin).
Multiple myeloma.
Dermatomyositis.
Parasitic infections.
Leukemia.
Lymphoma.

CALCIFICATIONS, GENITAL TRACT, FEMALE ON X-RAY[36]

ICD-10CM #	E83.59	Other disorders of calcium metabolism

FEMALE GENITAL TRACT CALCIFICATION

Uterus
Leiomyomas.
Squamous cell carcinoma.
Adenocarcinoma of endometrium.
Leiomyosarcoma.
Lithopedion.
Fallopian Tubes
Ovary.
Dermoid cyst.
Serous cystadenoma/carcinoma.
Tuberculosis.
Cysts.
Autoamputation.

CALCIFICATIONS, LIVER ON X-RAY[36]

ICD-10CM #	K76.89	Other specified diseases of liver
	NEC K75.3	Granuloma, hepatic

LIVER CALCIFICATION

Common
Granuloma (tuberculosis, histoplasmosis, brucellosis).
Multiple scattered round densities.
Hydatid cyst:
Fine curvilinear in wall, or dense and irregular if contracted.
Primary liver tumor (hemangioma, hepatoblastoma, hepatoma, cholangiocarcinoma).
Irregular patterns or multiple nodules.
Metastases (mucinous primary of colon or breast, cystadenocarcinoma of ovary).
Finely stippled, may be extensive.
Uncommon
Hepatic artery aneurysm.
Armillifer armillatus infestation.
Chronic granulomatous disease of childhood.
Cyst (congenital or acquired).
Hematoma.
Intrahepatic gallstones.
Old liver abscess.
Portal vein thrombosis.
Differentiate
Hemochromatosis.
Thorotrast, thallium, iron.

CALCIFICATIONS, PANCREAS ON X-RAY[36]

ICD-10CM #	K86.8	Calcification, pancreas

PANCREATIC CALCIFICATION

Common
Chronic pancreatitis.
Uncommon
Acute pancreatitis (saponification).
Tumors:
Cystadenoma.
Cystadenocarcinoma.
Islet cell tumor.
Metastases.
Hereditary pancreatitis (large clumps).
Hemorrhage.
Hyperparathyroidism.
Pseudocyst.
Cavernous lymphangioma.
Mucoviscidosis.
Kwashiorkor.

CALCIFICATIONS, SPLEEN ON X-RAY[36]

ICD-10CM #	D73.8	Calcification, spleen

SPLENIC CALCIFICATION

Larger than 10 mm
Splenic artery aneurysm.
Splenic artery atheroma.
Cyst:
Posttraumatic.
Dermoid.
Epidermoid.
Hydatid.
Hematoma.
Infarct.
Abscess.
Tuberculosis.
Smaller than 10 mm
Histoplasmosis.
Tuberculosis.
Phleboliths.
Armillifer armillatus infestation.
Brucellosis.
Infarcts.

CALCIFICATIONS, VALVULAR ON X-RAY[36]

ICD-10CM #	I51.5	Calcification, heart

CAUSES OF RADIOGRAPHICALLY VISIBLE VALVE CALCIFICATION

Aortic Valve
Rheumatic aortic valve disease.
Bicuspid aortic valve.
Age/degenerate aortic valve.
Syphilis.
Ankylosing spondylitis.
Homograft calcification.
Mitral Valve
Rheumatic mitral valve disease.
Mitral annulus calcification.
Old vegetation (may only be visible on CT).
Homograft calcification.
Pulmonary Valve
Congenital pulmonary valve stenosis.
Rheumatic pulmonary valve disease (rare).
Fallot tetralogy (usually after repair).
Pulmonary hypertension.
Homograft calcification.
Tricuspid Valve
Rheumatic tricuspid valve disease.
Old vegetation (may only be visible on ultrafast CT).

CALCIUM STONES

ICD-10CM # N20.9 Urinary calculus, unspecified

Medications (e.g., antacids, loop diuretics, vitamin D, acetazolamide, glucocorticoids).
Primary hyperparathyroidism.
Hypercalcemia from malignancy.
Sarcoidosis.
Prolonged immobilization.
Hyperoxaluria (e.g., Crohn disease, celiac disease, chronic pancreatitis).
Hyperuricosuria (e.g., hyperuricemia, excessive dietary purine, allopurinol, probenecid).
Renal tubular acidosis.
Milk-alkali syndrome.
Thyrotoxicosis.
Hypocitraturia (e.g., metabolic acidosis, hypomagnesemia, hypokalemia).

CARDIAC ARREST, NONTRAUMATIC[58]

ICD-10CM # I46.9 Cardiac arrest, cause unspecified

Cardiac (coronary artery disease, cardiomyopathies, structural abnormalities, valve dysfunction, arrhythmias).
Respiratory (upper airway obstruction, hypoventilation, pulmonary embolism, asthma, COPD exacerbation, pulmonary edema).
Circulatory (tension pneumothorax, pericardial tamponade, PE, hemorrhage, sepsis).
Electrolyte abnormalities (hypokalemia or hyperkalemia, hypomagnesemia or hypermagnesemia, hypocalcemia).
Medications (tricyclic antidepressants, digoxin, theophylline, calcium channel blockers).
Drug abuse (cocaine, heroin, amphetamines).
Toxins (carbon monoxide, cyanide).
Environmental (drowning/near-drowning, electrocution, lightning, hypothermia or hyperthermia, venomous snakes).

CARDIAC DEATH, SUDDEN[3]

ICD-10CM # Z86.74 Personal history of sudden cardiac arrest

Ventricular tachycardia.
Bradyarrhythmia, sick sinus syndrome.
Aortic stenosis.
Tetralogy of Fallot.
Pericardial tamponade.
Cardiac tumors.
Complications of infective endocarditis.
Hypertrophic cardiomyopathy (arrhythmia or obstruction).
Myocardial ischemia.
Atherosclerosis.
Prinzmetal angina.
Kawasaki arteritis.

CARDIAC ENLARGEMENT[33]

ICD-10CM # I51.7 Cardiomegaly
Q23.8 Other congenital malformations of aortic and mitral valves
Q24.8 Other specified congenital malformations of heart
I11.9 Hypertensive heart disease without heart failure

CHAMBER ENLARGEMENT

Chronic Volume Overload
Mitral or aortic regurgitation.
Left-to-right shunt (PDA, VSD, AV fistula).
Cardiomyopathy
Ischemic.
Nonischemic.
Decompensated Pressure Overload
Aortic stenosis.
Hypertension.
High-Output States
Severe anemia.
Thyrotoxicosis.
Bradycardia
Severe sinus bradycardia.
Complete heart block.

LEFT ATRIUM

LV failure of any cause.
Mitral valve disease.
Myxoma.

RIGHT VENTRICLE

Chronic volume overload.
Tricuspid or pulmonic regurgitation.
Left-to-right shunt (ASD).
Decompensated pressure overload:
- Pulmonic stenosis.
- Pulmonary artery hypertension:
  - Primary.
  - Secondary (PE, COPD).
  - Pulmonary venoocclusive disease.

RIGHT ATRIUM

RV failure of any cause.
Tricuspid valve disease.
Myxoma.
Ebstein anomaly.

MULTICHAMBER ENLARGEMENT

Hypertrophic cardiomyopathy.
Acromegaly.
Severe obesity.

PERICARDIAL DISEASE

Pericardial effusion with or without tamponade.
Effusive constrictive disease.
Pericardial cyst, loculated effusion.

PSEUDOCARDIOMEGALY

Epicardial fat.
Chest wall deformity (pectus excavatum, straight back syndrome).
Low lung volumes.
AP chest x-ray.
Mediastinal tumor, cyst.

CARDIAC MASSES[95]

ICD-10CM # C38.0 Malignant neoplasm of heart
D15.1 Benign neoplasm of heart

Intracardiac thrombus.
Focal myocardial hypertrophy.
Left ventricular noncompaction.
Infectious disease (abscess).
Primary cardiac tumor.
Secondary cardiac tumor (metastasis).
Lipomatous hypertrophy of septum.
Cyst.
Imaging artifact.

CARDIAC MURMURS

ICD-10CM # R01.0 Benign and innocent cardiac murmurs
R01.1 Cardiac murmur, unspecified

SYSTOLIC

Mitral regurgitation (MR).
Tricuspid regurgitation (TR).
Ventricular septal defect (VSD).
Aortic stenosis (AS).
Idiopathic hypertrophic subaortic stenosis (IHSS).
Pulmonic stenosis (PS).
Innocent murmur of childhood.
Coarctation of aorta.
Mitral valve prolapse (MVP).

DIASTOLIC

Aortic regurgitation (AR).
Atrial myxoma.
Mitral stenosis (MS).
Pulmonary artery branch stenosis.
Tricuspid stenosis (TS).
Graham Steell murmur (diastolic decrescendo murmur heard in severe pulmonary hypertension).
Pulmonic regurgitation (PR).
Severe mitral regurgitation (MR).
Austin Flint murmur (diastolic rumble heard in severe AR).
Severe VSD and patent ductus arteriosus.

CONTINUOUS

Patent ductus arteriosus.
Pulmonary AV fistula.

CARDIAC TUMORS[34]

ICD-10CM # C38.0 Malignant neoplasm of heart
D15.1 Benign neoplasm of heart

PRIMARY

Benign:
- Myxoma.
- Lipoma.
- Fibroma.
- Rhabdomyoma.
- Fibroelastoma.

Malignant:
- Sarcoma.
- Mesothelioma.
- Lymphoma.

SECONDARY

Direct Extension
Lung cancer.
Breast cancer.
Mediastinal tumors.

Metastatic Tumors
Malignant melanoma.
Leukemia.
Lymphoma.
Venous Extension
Renal cell cancer.
Adrenal cancer.
Liver cancer.

CARDIOEMBOLISM

ICD-10CM # I21.3 ST Elevation (STEMI) myocardial infarction of unspecified site
I21.9 Acute myocardial infarction, unspecified

Acute MI.
Atrial fibrillation.
Left ventricular aneurysm.
Valvular heart disease (e.g., rheumatic mitral valve disease, mitral valve prolapse).
Dilated cardiomyopathy.
Atrial septal defect.
Patent foramen ovale.
Cardioversion for atrial fibrillation.
Infective endocarditis.
Atrial septal aneurysm.
Sick sinus syndrome and cardiac arrhythmias.
Nonbacterial thrombotic endocarditis.
Prosthetic heart valves.
Atrial myxoma and other intracardiac tumors.
Cyanotic heart disease.
Balloon angioplasty.
Coronary artery bypass grafting.
Aneurysms of sinus of Valsalva.
Other: VVI pacing, ventricular support devices, heart transplantation, intracardiac defects with paradoxical embolism.

CARDIOGENIC SHOCK

ICD-10CM # R57.0 Cardiogenic shock

Myocardial infarction.
Arrhythmias.
Pericardial effusion/tamponade.
Chest trauma.
Valvular heart disease.
Myocarditis.
Cardiomyopathy.
CHF, end-stage.

CATARACTS, PEDIATRIC AGE

ICD-10CM # H26.0 Infantile, juvenile, and presenile cataracts

DEVELOPMENTAL VARIANTS

Prematurity (Y-suture vacuoles) with or without retinopathy of prematurity.

GENETIC DISORDERS

Simple Mendelian Inheritance
Autosomal dominant (most common).
Autosomal recessive.
X-linked.
Major Chromosomal Defects
Trisomy disorders (13, 18, 21).
Turner syndrome (45X).
Deletion syndromes (11p13, 18p, 18q).
Duplication syndromes (3q, 20p, 10q).
Multisystem Genetic Disorders
Alport syndrome (hearing loss, renal disease).
Alström syndrome (nerve deafness, diabetes mellitus).
Apert disease (craniosynostosis, syndactyly).
Cockayne syndrome (premature senility, skin photosensitivity).
Conradi disease (chondrodysplasia punctata).
Crouzon disease (dysostosis craniofacialis).
Hallermann-Streiff syndrome (microphthalmia, small pinched nose, skin atrophy, hypotrichosis).
Hypohidrotic ectodermal dysplasia (anomalous dentition, hypohidrosis, hypotrichosis).
Ichthyosis (keratinizing disorder with thick, scaly skin).
Incontinentia pigmenti (dental anomalies, mental retardation, cutaneous lesions).
Lowe syndrome (oculocerebrorenal syndrome: hypotonia, renal disease).
Marfan syndrome.
Marinesco-Sjögren syndrome (cerebellar ataxia, hypotonia).
Meckel-Gruber syndrome (renal dysplasia, encephalocele).
Myotonic dystrophy.
Nail-patella syndrome (renal dysfunction, dysplastic nails, hypoplastic patella).
Nevoid basal cell carcinoma syndrome (autosomal dominant, basal cell carcinoma erupts in childhood).
Peters anomaly (corneal opacifications with iris-corneal dysgenesis).
Reiger syndrome (iris dysplasia, myotonic dystrophy).
Rothmund-Thomson syndrome (poikiloderma: skin atrophy).
Rubinstein-Taybi syndrome (broad great toe, mental retardation).
Smith-Lemli-Opitz syndrome (toe syndactyly, hypospadias, mental retardation).
Sotos syndrome (cerebral gigantism).
Spondyloepiphyseal dysplasia (dwarfism, short trunk).
Werner syndrome (premature aging in 2nd decade of life).
Inborn Errors of Metabolism
Abetalipoproteinemia (absent chylomicrons, retinal degeneration).
Fabry disease (α-galactosidase A deficiency).
Galactokinase deficiency.
Galactosemia (galactose-1-phosphate uridyl transferase deficiency).
Homocystinemia (subluxation of lens, mental retardation).
Mannosidosis (acid α-mannosidase deficiency).
Niemann-Pick disease (sphingomyelinase deficiency).
Refsum disease (phytanic acid α-hydrolase deficiency).
Wilson disease (accumulation of copper leads to cirrhosis and neurologic symptoms).

ENDOCRINOPATHIES

Hypocalcemia (hypoparathyroidism).
Hypoglycemia.
Diabetes mellitus.

CONGENITAL INFECTIONS

Toxoplasmosis.
Cytomegalovirus infection.
Syphilis.
Rubella.
Perinatal herpes simplex infection.
Measles (rubeola).
Poliomyelitis.
Influenza.
Varicella-zoster.

OCULAR ANOMALIES

Microphthalmia.
Coloboma.
Aniridia.
Mesodermal dysgenesis.
Persistent papillary membrane.
Posterior lenticonus.
Persistent hyperplastic primary vitreous.
Primitive hyaloid vascular system.

MISCELLANEOUS DISORDERS

Atopic dermatitis.
Drugs (corticosteroids).
Radiation.
Trauma.
Idiopathic

CAVITARY LESION ON CHEST X-RAY[35]

ICD-10CM # R91.8 Other nonspecific abnormal finding of lung field

NECROTIZING INFECTIONS

Bacteria: anaerobes, *Staphylococcus aureus*, enteric gram-negative bacteria, *Pseudomonas aeruginosa*, *Legionella* species, *Haemophilus influenzae*, *Streptococcus pyogenes*, *Streptococcus pneumoniae, Rhodococcus, Actinomyces*.
Mycobacteria: *Mycobacterium tuberculosis, Mycobacterium kansasii*, MAI.
Bacteria-like: *Nocardia* species.
Fungi: *Coccidioides immitis, Histoplasma capsulatum, Blastomyces hominis, Aspergillus* species, *Mucor* species.
Parasitic: *Entamoeba histolytica, Echinococcus, Paragonimus westermani*.

CAVITARY INFARCTION

Bland infarction (with or without superimposed infection).
Lung contusion.

SEPTIC EMBOLISM

S. aureus, anaerobes, others.

VASCULITIS

Granulomatosis with polyangiitis, periarteritis.

NEOPLASMS

Bronchogenic carcinoma, metastatic carcinoma, lymphoma.

MISCELLANEOUS LESIONS

Cysts, blebs, bullae, or pneumatocele with or without fluid collections.
Sequestration.
Empyema with air-fluid level.
Bronchiectasis.

CEREBRAL INFARCTION SECONDARY TO INHERITED DISORDERS

ICD-10CM # I63.50 Cerebral infarction due to unspecified occlusion or stenosis of unspecified cerebral artery

Homocystinuria.
Marfan syndrome.
Ehlers-Danlos syndrome.
Rendu-Osler-Weber syndrome.
Pseudoxanthoma elasticum.
Fabry disease.

CEREBRAL VASCULITIS, CAUSES[29]

ICD-10CM # Varies with specific diagnosis

PRIMARY CEREBRAL VASCULITIDES

Takayasu arteritis.
Primary cerebral vasculitis.
Polyarteritis nodosa.

SECONDARY VASCULITIDES

Immune Disorders
Systemic lupus erythematosus.
Wegner granulomatosis.
Kawasaki syndrome.
Sarcoidosis.
Henoch-Schönlein purpura.
Primary Intracranial Infections
Bacterial meningitis (especially *Diplococcus pneumoniae*).
Tuberculous meningitis.
Mycotic infections.
Cat-scratch disease.
Human immunodeficiency virus/acquired immunodeficiency syndrome.
Malaria.
Lyme disease.
Rickettsial infections.
Brucellosis.

CEREBROVASCULAR DISEASE, ISCHEMIC[93]

ICD-10CM # I67.9 Cerebrovascular disease, unspecified

VASCULAR DISORDERS

Large-vessel atherothrombotic disease.
Lacunar disease.
Arterial-to-arterial embolization.
Carotid or vertebral artery dissection.
Fibromuscular dysplasia.
Migraine.
Venous thrombosis.
Radiation.
Complications of arteriography.
Multiple, progressive intracranial arterial occlusions.

INFLAMMATORY DISORDERS

Giant cell arteritis.
Polyarteritis nodosa.
SLE.
Granulomatous angiitis.
Takayasu disease.
Arteritis associated with amphetamine, cocaine, or phenylpropanolamine.
Syphilis, mucormycosis.
Sjögren syndrome.
Behçet syndrome.

CARDIAC DISORDERS

Rheumatic heart disease.
Mural thrombus.
Arrhythmias.
Mitral valve prolapse.
Prosthetic heart valve.
Endocarditis.
Myxoma.
Paradoxical embolus.

HEMATOLOGIC DISORDERS

Thrombotic thrombocytopenic purpura.
Sickle cell disease.
Hypercoagulable states.
Polycythemia.
Thrombocytosis.
Leukocytosis.
Lupus anticoagulant.

CERVICAL INSTABILITY, PEDIATRIC

ICD-10CM # M50 Cervical disc disorders

CONGENITAL

Vertebral (Bony Anomalies)
Craniooccipital defects (occipital vertebrae, basilar impression, occipital dysplasias, condylar hypoplasia, occipitalized atlas).
Atlantoaxial defects (aplasia of atlas arch, aplasia of odontoid process).
Subaxial anomalies (failure of segmentation and/or fusion, spina bifida, spondylolisthesis).
Ligamentous or Combined Anomalies
Found at birth as an element of somatogenic aberration.
Syndromic Disorders
Down syndrome.
Klippel-Feil syndrome.
22q11.2 deletion syndrome.
Larsen syndrome.
Marfan syndrome.
Ehlers-Danlos syndrome.

ACQUIRED

Trauma.
Infection (pyogenic, granulomatous).
Tumor (including neurofibromatosis).
Inflammatory conditions (e.g., juvenile rheumatoid arthritis).
Osteochondrodysplasias (e.g., achondroplasia, diastrophic dysplasia, metatropic dysplasia, spondyloepiphyseal dysplasia).
Storage disorders (e.g., mucopolysaccharidoses).
Metabolic disorders (rickets).
Miscellaneous (including osteogenesis imperfecta, sequela of surgery).

CHEST PAIN, CHILDREN[9]

ICD-10CM # R07.9 Chest pain, unspecified
R07.82 Intercostal pain
R07.89 Other chest pain
R07.1 Chest pain on breathing
R07.81 Pleurodynia

MUSCULOSKELETAL (COMMON)

Trauma (accidental, abuse).
Exercise, overuse injury (strain, bursitis).
Costochondritis (Tietze syndrome).
Herpes zoster (cutaneous).
Pleurodynia.
Fibrositis.
Slipping rib.
Sickle cell anemia vasoocclusive crisis.
Osteomyelitis (rare).
Primary or metastatic tumor (rare).

PULMONARY (COMMON)

Pneumonia.
Pleurisy.
Asthma.
Chronic cough.
Pneumothorax.
Infarction (sickle cell anemia).
Foreign body.
Embolism (rare).
Pulmonary hypertension (rare).
Tumor (rare).

GASTROINTESTINAL (LESS COMMON)

Esophagitis (gastroesophageal reflux).
Esophageal foreign body.
Esophageal spasm.
Cholecystitis.
Subdiaphragmatic abscess.
Perihepatitis (Fitz-Hugh-Curtis syndrome).
Peptic ulcer disease.

CARDIAC (LESS COMMON)

Pericarditis.
Postpericardiotomy syndrome.
Endocarditis.
Mitral valve prolapse.
Aortic or subaortic stenosis.
Arrhythmias.
Marfan syndrome (dissecting aortic aneurysm).
Anomalous coronary artery.
Kawasaki disease.
Cocaine, sympathomimetic ingestion.
Angina (familial hypercholesterolemia).

IDIOPATHIC (COMMON)

Anxiety, hyperventilation.
Panic disorder.

OTHER (LESS COMMON)

Spinal cord or nerve root compression.
Breast-related pathologic condition.
Castleman disease (lymph node neoplasm).

CHEST PAIN, NONPLEURITIC[20]

ICD-10CM # R07.9 Chest pain, unspecified
R07.82 Intercostal pain
R07.89 Other chest pain

Cardiac: myocardial ischemia/infarction, myocarditis.

Esophageal: spasm, esophagitis, ulceration, neoplasm, achalasia, diverticula, foreign body.
Referred pain from subdiaphragmatic GI structures.
Gastric and duodenal: hiatal hernia, neoplasm, PUD.
Gallbladder and biliary: cholecystitis, cholelithiasis, impacted stone, neoplasm.
Pancreatic: pancreatitis, neoplasm.
Dissecting aortic aneurysm.
Pain originating from skin, breasts, and musculoskeletal structures: herpes zoster, mastitis, cervical spondylosis.
Mediastinal tumors: lymphoma, thymoma.
Pulmonary: neoplasm, pneumonia, pulmonary embolism/infarction.
Psychoneurosis.
Chest pain associated with mitral valve prolapse.

CHEST PAIN, PLEURITIC

ICD-10CM # R07.1 Chest pain on breathing
R07.81 Pleurodynia

Cardiac: pericarditis, postpericardiotomy/Dressler syndrome.
Pulmonary: pneumothorax, hemothorax, embolism/infarction, pneumonia, empyema, neoplasm, bronchiectasis, pneumomediastinum, TB, carcinomatous effusion.
GI: liver abscess, pancreatitis, esophageal rupture, Whipple disease with associated pericarditis or pleuritis.
Subdiaphragmatic abscess.
Pain originating from skin and musculoskeletal tissues: costochondritis, chest wall trauma, fractured rib, interstitial fibrositis, myositis, strain of pectoralis muscle, herpes zoster, soft tissue and bone tumors.
Collagen vascular diseases with pleuritis.
Psychoneurosis.
Familial Mediterranean fever.

CHEST WALL TUMORS, PRIMARY[15]

ICD-10CM # Varies with specific diagnosis

SOFT TISSUE

Benign
Lipoma.
Hemangioma.
Lymphangioma.
Fibroma.
Rhabdomyoma.
Neurofibroma.
Desmoid tumor.
Malignant
Malignant fibrous histiocytoma.
Rhabdosarcoma.
Liposarcoma.
Neurofibrosarcoma.
Leiomyosarcoma.

BONY AND CARTILAGINOUS

Benign
Fibrous dysplasia.
Osteochondroma.
Chondroma.
Askin tumor.
Plasmacytoma.
Malignant
Chondrosarcoma.
Osteogenic sarcoma.
Ewing sarcoma.

CHIASMAL DISEASE[12]

ICD-10CM # Varies with specific diagnosis

CAUSES OF CHIASMAL DISEASE

Tumors
Pituitary adenomas.
Craniopharyngioma.
Meningioma.
Glioma.
Chordoma.
Dysgerminoma.
Nasopharyngeal tumors.
Metastases.
Non-neoplastic masses
Aneurysm.
Rathke pouch cysts.
Fibrous dysplasia.
Sphenoidal sinus mucocele.
Arachnoid cysts.
Miscellaneous
Demyelination.
Inflammation (e.g., sarcoidosis).
Trauma.
Radiation-induced necrosis.
Toxicity (e.g., ethambutol).
Vasculitis.

CHILDHOOD EOSINOPHILIA

ICD-10CM # D72.1 Eosinophilia

PHYSIOLOGIC

Prematurity.
Infants receiving hyperalimentation.
Familial.

INFECTIOUS

Parasitic (with tissue-invasive helminths, e.g., trichinosis, strongyloidiasis, pneumocystosis, filariasis, cysticercosis, cutaneous and visceral larva migrans, echinococcosis).
Bacterial (brucellosis, tularemia, cat-scratch disease, *Chlamydia*).
Fungal (histoplasmosis, blastomycosis, coccidioidomycosis, allergic bronchopulmonary aspergillosis).
Mycobacterial (tuberculosis, leprosy).
Viral (hepatitis A, hepatitis B, hepatitis C, Epstein-Barr virus).

PULMONARY

Allergic (rhinitis, asthma).
Loeffler syndrome.
Hypersensitivity pneumonitis.
Eosinophilic pneumonia.
Pulmonary interstitial eosinophilia.

DERMATOLOGIC

Atopic dermatitis.
Pemphigus.
Dermatitis herpetiformis.
Infantile eosinophilic pustular folliculitis.
Episodic angioedema and urticaria.
Eosinophilic fasciitis (Schulman syndrome).
Eosinophilic cellulitis (Wells syndrome).
Kimura disease.

ONCOLOGIC

Neoplasm (lung, GI, uterine).
Hodgkin disease.
Leukemia.
Myelofibrosis.

IMMUNOLOGIC

T-cell immunodeficiencies.
Hyperimmunoglobulin E (Job) syndrome.
Wiskott-Aldrich syndrome.
Graft-versus-host disease.
Drug hypersensitivity.
Post-irradiation.
Post-splenectomy.

ENDOCRINE

Post-adrenalectomy.
Addison disease.
Panhypopituitarism.

CARDIOVASCULAR

Loeffler disease (fibroplastic endocarditis).
Congenital heart disease.
Hypersensitivity vasculitis.

GASTROINTESTINAL

Milk protein allergy.
Inflammatory bowel disease.
Eosinophilic esophagitis.
Eosinophilic gastroenteritis.

CHOLANGITIS, ACUTE[15]

ICD-10CM # K83.0 Cholangitis

NONIATROGENIC

Benign Conditions
Choledocholithiasis.
Primary.
Secondary.
Pancreatitis (chronic/acute), including pancreatic pseudocyst.
Papillary stenosis.
Mirizzi syndrome.
Choledochal cysts (type V, Caroli disease).
Primary sclerosing cholangitis.
Malignancies
Pancreatic cancer.
Cholangiocarcinoma.
Porta hepatis tumor/metastasis.

IATROGENIC

Obstructed biliary endoprosthesis.
Iatrogenic biliary stricture.
Direct surgical trauma.
Ischemia-induced stricture.
Anastomotic stricture (biliobiliary/bilioenteric anastomosis).

CHOLESTASIS[32]

ICD-10CM # K80.65 Calculus of gallbladder and bile duct with chronic cholecystitis with obstruction

EXTRAHEPATIC

Choledocholithiasis.
Bile duct stricture.
Cholangiocarcinoma.
Pancreatic carcinoma.
Chronic pancreatitis.
Papillary stenosis.
Ampullary cancer.
Primary sclerosing cholangitis.
Choledochal cysts.
Parasites (e.g., ascaris, clonorchis).
AIDS.
Cholangiography.
Biliary atresia.
Portal lymphadenopathy.
Mirizzi syndrome.

INTRAHEPATIC

Viral hepatitis.
Alcoholic hepatitis.
Drug induced.
Ductopenia syndromes.
Primary biliary cirrhosis.
Benign recurrent intrahepatic cholestasis.
Byler disease.
Primary sclerosing cholangitis.
Alagille syndrome.
Sarcoid.
Lymphoma.
Postoperative.
Total parenteral nutrition.
α-1-antitrypsin deficiency.

CHOLESTASIS, NEONATAL AND INFANTILE, DIFFERENTIAL DIAGNOSIS[53]

ICD-10CM # 026.6 Liver disorders in pregnancy, childbirth and the puerperium

INFECTIOUS

Generalized bacterial sepsis.
Viral hepatitis:
- Hepatitis A, B, C, D.
- Cytomegalovirus.
- Rubella virus.
- Herpesvirus: herpes simplex, human herpesvirus 6 and 7.
- Varicella virus.
- Coxsackievirus.
- Echovirus.
- Reovirus type 3.
- Parvovirus B19.
- HIV.
- Adenovirus.

Others:
- Toxoplasmosis.
- Syphilis.
- Tuberculosis.
- Listeriosis.
- Urinary tract infection.

TOXIC

Sepsis.
Parenteral nutrition related.
Drug related.

METABOLIC

Disorders of amino acid metabolism:
- Tyrosinemia.

Disorders of lipid metabolism:
- Wolman disease.
- Niemann-Pick disease (type C).
- Gaucher disease.

Cholesterol ester storage disease.
Disorders of carbohydrate metabolism:
- Galactosemia.
- Fructosemia.
- Glycogenosis IV.

Disorders of bile acid biosynthesis.
Other metabolic defects:
- α1-Antitrypsin deficiency.
- Cystic fibrosis.
- Hypopituitarism.
- Hypothyroidism.
- Zellweger (cerebrohepatorenal) syndrome.
- Neonatal iron storage disease.
- Indian childhood cirrhosis/infantile copper overload.
- Congenital disorders of glycosylation.
- Mitochondrial hepatopathies.
- Citrin deficiency.

GENETIC OR CHROMOSOMAL

Trisomy 17, 18, 21.
Donahue syndrome.

INTRAHEPATIC CHOLESTASIS SYNDROMES

"Idiopathic" neonatal hepatitis.
Alagille syndrome (arteriohepatic dysplasia).
Nonsyndromic bile duct paucity syndrome.
Intrahepatic cholestasis (PFIC):
- FIC-1 deficiency.
- BSEP deficiency.
- MDR3 deficiency.

Familial benign recurrent cholestasis associated with lymphedema (Aagenaes).
Congenital hepatic fibrosis.
Caroli disease (cystic dilatation of intrahepatic ducts).

EXTRAHEPATIC DISEASES

Biliary atresia.
Sclerosing cholangitis.
Bile duct stricture/stenosis.
Choledochal-pancreaticoductal junction anomaly.
Spontaneous perforation of the bile duct.
Choledochal cyst.
Mass (neoplasia, stone).
Bile/mucous plug ("inspissated bile").

MISCELLANEOUS

Shock and hypoperfusion.
Associated with enteritis.
Associated with intestinal obstruction.
Neonatal lupus erythematosus.
Myeloproliferative disease (trisomy 21).
Hemophagocytic lymphohistiocytosis.
Arthrogryposis cholestatic pigmentary syndrome.

CHOLESTATIC LIVER ENZYME ELEVATION, EXTRAHEPATIC CAUSES[26]

ICD-10CM # Varies with specific diagnosis

EXTRAHEPATIC CAUSES OF CHOLESTATIC LIVER ENZYMES IN ADULTS

Intrinsic

Choledocholithiasis.
Immune-mediated duct injury:
- Autoimmune pancreatitis.
- PSC.

Malignancy:
- Ampullary cancer.
- Cholangiocarcinoma.

Infections:
- AIDS cholangiopathy:
  - Cytomegalovirus.
  - Cryptosporidiosis.
  - Microsporidiosis.
- Parasitic infections:
  - Ascariasis.

Extrinsic

Malignancy:
- Gallbladder cancer.
- Metastases, including portal adenopathy from metastases.
- Pancreatic cancer.

Mirizzi syndrome.
Pancreatitis.
Pancreatic pseudocyst.

CHOLESTATIC LIVER ENZYME ELEVATION, INTRAHEPATIC CAUSES[26]

ICD-10CM # Varies with specific causes

INTRAHEPATIC CAUSES OF CHOLESTATIC LIVER ENZYME ELEVATIONS IN ADULTS

Drugs[11]

Bland cholestasis:
- Anabolic steroids.
- Estrogens.

Cholestatic hepatitis:
- Angiotensin-converting enzyme inhibitors: captopril, enalapril.
- Antimicrobials: amoxicillin-clavulanic acid, ketoconazole.
- Azathioprine.
- Chlorpromazine.
- NSAIDs: sulindac, piroxicam.

Granulomatous hepatitis:
- Allopurinol.
- Antibiotics: sulfonamides.
- Antiepileptics: carbamazepine, phenytoin.

[11] Categorized by histologic pattern. Drug lists are not meant to be comprehensive.

Cardiovascular agents: hydralazine, procainamide, quinidine.
Phenylbutazone.
Vanishing bile duct syndrome:
Amoxicillin-clavulanic acid.
Chlorpromazine.
Dicloxacillin.
Flucloxacillin.
Macrolides.
PBC
PSC
Granulomatous Liver Disease
Infections:
Brucellosis.
Fungal: histoplasmosis, coccidioidomycosis.
Leprosy.
Q fever.
Schistosomiasis.
TB, *Mycobacterium avium* complex, bacillus Calmette-Guérin.
Sarcoidosis.
Idiopathic granulomatous hepatitis.
Other:
Crohn disease.
Heavy metal exposure: beryllium, copper.
Hodgkin disease.
Viral Hepatitis
HAV and HEV.
HBV and HCV, including fibrosing cholestatic hepatitis.
EBV.
Cytomegalovirus.
Idiopathic Adulthood Ductopenia
Genetic Conditions
Progressive familial intrahepatic cholestasis:
Type 1 (formerly Byler disease).
Type 2.
Type 3.
Benign recurrent intrahepatic cholestasis:
Type 1.
Type 2.
CF.
Malignancy
Hepatocellular carcinoma.
Metastatic disease.
Paraneoplastic syndrome:
Non-Hodgkin lymphoma.
Prostate cancer.
Renal cell cancer.
Infiltrative Liver Disease
Amyloidosis.
Lymphoma.
Intrahepatic Cholestasis of Pregnancy
TPN:
Graft-versus-host disease
Sepsis

CHOREA

ICD-10CM # G25.4 Drug-induced chorea
G25.5 Other chorea

Medications (e.g., neuroleptics, tricyclics, antiparkinsonian drugs).
Cerebral palsy.
Huntington disease.
Benign hereditary chorea.
Thyroid disorder (hyperthyroidism, hypothyroidism).
Friedreich ataxia.
Ataxia-telangiectasia.
Hypoglycemia, hyperglycemia.
Electrolyte abnormalities (hyponatremia, hypocalcemia, hypomagnesemia, hypernatremia).
Vitamin B_{12} deficiency.
SLE.
Wilson disease.
Alcohol.
Cocaine.
Carbon monoxide poisoning.
Mercury poisoning.

CHOREA, PEDIATRIC PATIENT[84]

ICD-10CM # G25.5 Other chorea

CAUSES OF CHOREA IN CHILDHOOD

Static Injury/Structural Disorders
Cerebral palsy.
Stroke.
Trauma.
Moyamoya disease.
Vasculitis.
Tumors.
Congenital malformations.
Joubert syndrome.
Hereditary/Degenerative Disorders
Ataxia-telangiectasia (A-T), and Ataxia-telangiectasia-like disorder (ATLD).
Ataxia oculomotor apraxia (AOA) (includes AOA-1, AOA-2, and early onset cerebellar ataxia and hypoalbuminemia [EOCA-HA]).
Fahr disease.
Pantothenate kinase-associated neurodegeneration (PKAN, associated with mutations in the pantothenate kinase-2 (*PANK-2*) gene), and other causes of neuronal brain iron accumulation (NBIA).
Metabolic Disorders
Acyl-coA dehydrogenase deficiencies.
Mitochondrial disorders, including Leigh syndrome.
GM_1 gangliosidosis.
Lesch-Nyhan disease.
Niemann-Pick type C.
Methylmalonic aciduria.
Nonketotic hyperglycemia.
Kernicterus.
Hypoparathyroidism.
Propionic acidemia.
Hypernatremia.
Hypomagnesemia.
Hypocalcemia.
Hypo- or hyperglycemia.
Vitamin E deficiency or malabsorption.
Bassen-Kornzweig disease.
Complications of cardiac bypass.
Infectious/Parainfectious Disease
Encephalitis/postencephalitis.
Immune-Mediated/Demyelinating Disorders
Sydenham chorea.
Lupus erythematosus.
Henoch-Schönlein purpura.
Anticardiolipin or antiphospholipid antibody syndrome.
Anti-NMDA antibody syndrome.
Drugs/Toxins
Neuroleptic medications, and neuroleptic-like antiemetics (haloperidol, chlorpromazine, pimozide, prochlorperazine, metoclopramide).
Calcium channel blockers (flunarizine, cinnarizine).
Antiseizure medications (phenytoin, carbamazepine, valproate, phenobarbital).
Anticholinergic medications (trihexyphenidyl, benztropine).
Antihistamines.
Tricyclic antidepressants.
Clomipramine.
Stimulants (including methylphenidate, dexamphetamine, pemoline, and bronchodilators).
Clonidine.
L-dopa.
Cocaine.
Bismuth.
Lithium.
Manganese.
Ethanol.
Carbon monoxide.
Oral contraceptives.
General anesthesia (including propofol)—during induction or emergence.
Paroxysmal Disorders
Complex migraine.
Alternating hemiplegia of childhood.
Paroxysmal kinesigenic dyskinesia (PKD).
Paroxysmal nonkinesigenic dyskinesia (PNKD).
Paroxysmal exercise-induced dyskinesia (PED).
Endocrine Disorders
Hyperthyroidism.
Pheochromocytoma.

CHOREOATHETOSIS[65]

ICD-10CM # G25.5 Choreoathetosis

SYSTEMIC DISEASES

SLE.
Polycythemia.
Thyrotoxicosis.
Rheumatic fever.
Cirrhosis of the liver (acquired hepatocerebral degeneration).
DM.
Wilson disease.

PRIMARY DEGENERATIVE BRAIN DISEASES

Huntington chorea.
Olivopontocerebellar atrophies.
Neuroacanthocytosis.

FOCAL BRAIN DISEASES

Hemichorea.
Stroke.
Tumor.
Arteriovenous malformation.

DRUG-INDUCED CHOREOATHETOSIS

Parkinson Disease Drugs
Levodopa.

EPILEPSY DRUGS

Phenytoin.
Carbamazepine.
Phenobarbital.
Gabapentin.
Valproate.
Psychostimulant Drugs
Cocaine.
Amphetamine.
Methamphetamine.
Dextroamphetamine.
Methylphenidate.
Pemoline.
Psychotropic Drugs
Lithium.
Tricyclic antidepressant drugs.
Oral Contraceptive Drugs
Cimetidine

CHYLOTHORAX

ICD-10CM # I89.8 Other specified noninfective disorders of lymphatic vessels and lymph nodes

Post-lymph node dissection of neck or chest.
Subclavian venous catheterization.
Thoracic aneurysm repair.
Trauma to chest and neck.
Mediastinal tumor resection.
Esophagectomy, pneumonectomy.
Lymphangitis, mediastinitis.
Neoplasms (lymphoma, carcinoma of esophagus, lung, mediastinal malignancies).
Sympathectomy.
Venous thrombosis.
Congenital.

CLOUDY URINE

ICD-10CM # R82 Other abnormal findings in urine

Concentrated urine.
Use of multivitamin supplements.
Diet high in purine-rich foods.
Pyuria.
Phosphaturia.
Urinary tract infection.
Lipiduria.
Chyluria.
Hyperoxaluria.

CLUBBING

ICD-10CM # R68.3 Clubbing of fingers

Pulmonary neoplasm (lung, pleura).
Other neoplasm (GI, liver, Hodgkin, thymus, osteogenic sarcoma).
Pulmonary infectious process (empyema, abscess, bronchiectasis, TB, chronic pneumonitis).
Extrapulmonary infectious process (subacute bacterial endocarditis, intestinal TB, bacterial or amebic dysentery, arterial graft sepsis).
Pneumoconiosis.
Cystic fibrosis.
Sarcoidosis.
Cyanotic congenital heart disease.
Endocrine (Graves disease, hyperparathyroidism).
Inflammatory bowel disease.
Celiac disease.
Chronic liver disease, cirrhosis (particularly biliary and juvenile).
Pulmonary AV malformations.
Idiopathic.
Thyroid acropachy.
Hereditary (pachydermoperiostosis).
Chronic trauma (jackhammer operators, machine workers).

COBALAMIN DEFICIENCY[45]

ICD-10CM # E53.8 Deficiency of other specified B group vitamins

ETIOPATHOPHYSIOLOGIC CLASSIFICATION OF COBALAMIN DEFICIENCY

Nutritional cobalamin deficiency (i.e., insufficient cobalamin intake):
  Vegetarians, poverty-imposed near-vegetarians, breastfed infants of mothers with pernicious anemia.
Abnormal intragastric events (i.e., inadequate proteolysis of food cobalamin):
  Atrophic gastritis, partial gastritis with hypochlorhydria, proton-pump inhibitors, H_2 blockers.
Loss or atrophy of gastric oxyntic mucosa (i.e., deficient intrinsic factor [IF] molecules):
  Total or partial gastrectomy, pernicious anemia, caustic destruction (lye).
Abnormal events in small bowel lumen:
  Inadequate pancreatic protease (e.g., R-cobalamin not degraded, cobalamin not transferred to IF):
    Insufficient pancreatic protease (i.e., pancreatic insufficiency).
    Inactivation of pancreatic protease (i.e., Zollinger–Ellison syndrome).
  Usurping of luminal cobalamin (i.e., inadequate cobalamin binding to IF):
  By bacteria, during stasis syndromes (e.g., blind loops, pouches of diverticulosis, strictures, fistulas, anastomosis), impaired bowel motility (e.g., scleroderma), hypogammaglobulinemia.
  By *Diphyllobothrium latum* (fish tapeworm).
Disorders of ileal mucosa/IF–cobalamin receptors (i.e., IF–cobalamin not bound to IF–cobalamin receptors):
  Diminished or absent IF–cobalamin receptors (e.g., ileal bypass, resection, fistula).
  Abnormal mucosal architecture/function (e.g., tropical or nontropical sprue, Crohn disease, tuberculosis ileitis, infiltration by lymphomas, amyloidosis).
  IF-/post-IF–cobalamin receptor defects (e.g., Imerslund–Gräsbeck syndrome, transcobalamin II [TC II] deficiency).
  Drug effects (e.g., slow K, metformin, cholestyramine, colchicine, neomycin).
Disorders of plasma cobalamin transport (i.e., TC II–cobalamin not delivered to TC II receptors):
  Congenital TC II deficiency, defective binding of TC II–cobalamin to TC II receptors (rare).
Metabolic disorders (i.e., cobalamin not used by cells):
  Inborn enzyme errors (rare).
  Acquired disorders (e.g., cobalamin functionally inactivated by irreversible oxidation, N_2O inhalation).

COGNITIVE IMPAIRMENT[83]

ICD-10CM # G31.84 Mild cognitive impairment, so stated

CAUSES OF COGNITIVE IMPAIRMENT: DIAGNOSES BY CATEGORIES WITH REPRESENTATIVE EXAMPLES

Degenerative:
Alzheimer disease.
Frontotemporal dementias.
Dementia with Lewy bodies.
Corticobasal degeneration.
Huntington disease.
Wilson disease.
Parkinson disease.
Multiple system atrophy.
Progressive supranuclear palsy.
Psychiatric:
Depression.
Schizophrenia.
Vascular:
Vascular dementia.
Binswanger encephalopathy.
Amyloid dementia.
Diffuse hypoxic/ischemic injury.
Obstructive:
Normal-pressure hydrocephalus.
Obstructive hydrocephalus.
Traumatic:
Chronic subdural hematoma.
Chronic traumatic encephalopathy.
Post-concussion syndrome.
Neoplastic:
Tumor: malignant, primary and secondary.
Tumor: benign (e.g., frontal meningioma).
Paraneoplastic limbic encephalitis.
Infections:
Chronic meningitis.
Post-herpes encephalitis.
Focal cerebritis/abscesses.
HIV dementia.
HIV-associated infection.
Syphilis.
Lyme encephalopathy.
Subacute sclerosing panencephalitis.
Creutzfeldt–Jakob disease.
Progressive multifocal leukoencephalopathy.
Parenchymal sarcoidosis.
Chronic systemic infection.
Demyelinating:
Multiple sclerosis.
Adrenoleukodystrophy.
Metachromatic leukodystrophy.

Autoimmune:
Systemic lupus erythematosus.
Polyarteritis nodosa.
Drugs/Toxins
Medications:
- Anticholinergics.
- Antihistamines.
- Anticonvulsants.
- β-blockers.
- Sedative–hypnotics.

Substance abuse:
Alcohol.
Inhalants.
Phencyclidine (PCP).
Toxins
Arsenic.
Bromide.
Carbon monoxide.
Lead.
Mercury.
Organophosphates.

COLIC, ACUTE ABDOMINAL[86]

ICD-10CM # R10.0 Acute abdomen

Acute gastroenteritis.
Food poisoning.
Nonspecific causes.
Constipation.
Gastric outlet obstruction:
- Chronic peptic ulceration.
- Gastric cancer.

Small bowel obstruction:
- Adhesions:
  - Postsurgical.
  - Inflammatory (e.g., diverticular).
  - Radiation.
  - Meckel diverticulum.
  - Metastatic.
- Stricture:
  - Ischemic.
  - Radiation.
  - Inflammatory (e.g., Crohn disease).
- Volvulus intussusception:
  - Tumor (e.g., Peutz-Jeghers syndrome).
  - Superior mesenteric artery syndrome.
- Intraluminal bolus:
  - Gallstone.
  - Bezoar.
- Hernia:
  - Abdominal wall.
  - Internal.
- Neoplasm:
  - Benign (e.g., leiomyoma).
  - Malignant (e.g., carcinoid tumor, adenocarcinoma).
- Large bowel obstruction:
  - Colon cancer.
  - Diverticular disease.
  - Volvulus.
- Uterine:
  - Missed abortion.
  - Parturition.
  - Period pain.

COLON ISCHEMIA[26]

ICD-10CM # Varies with specific diagnosis

CAUSES OF COLON ISCHEMIA

Acute pancreatitis.
Allergy.
Amyloidosis.
Heart failure or cardiac arrhythmias.
Hematologic disorders and coagulopathies:
- Activated protein C resistance.
- Antithrombin deficiency.
- Factor V Leiden mutation.
- Paroxysmal nocturnal hemoglobinuria.
- Polycythemia vera.
- Protein C and S deficiencies.
- Prothrombin G20210A mutation.
- Sickle cell disease.

Infection:
- Bacteria (*Escherichia coli* O157:H7).
- Parasites (*Angiostrongylus costaricensis*).
- Viruses (HBV, HCV, cytomegalovirus).

Inferior mesenteric artery thrombosis.
Long-distance running.
Medications and toxins:
- Alosetron.
- Cocaine.
- Danazol.
- Digitalis compounds.
- Ergots.
- Estrogens.
- Flutamide.
- Glycerin enema.
- Gold salts.
- Immunosuppressive agents.
- Interferon-α.
- Methamphetamine.
- NSAIDs.
- Penicillin.
- Phenylephrine.
- Polyethylene glycol 3350 colon lavage solutions.
- Pit viper toxin.
- Progestins.
- Pseudoephedrine.
- Psychotropic drugs.
- Saline laxatives.
- Sumatriptan.
- Tegaserod.
- Vasopressin.

Pheochromocytoma.
Ruptured ectopic pregnancy.
Shock.
Strangulated hernia.
Surgery/procedures:
- Aortic aneurysmectomy.
- Aortoiliac reconstruction.
- Barium enema.
- Colectomy with inferior mesenteric artery ligation.
- Colon bypass.
- Colonoscopy.
- Exchange transfusions.
- Gynecologic operations.
- Lumbar aortography.

Thromboembolism:
- Cholesterol (atheroembolism).
- Myxoma (left atrial).

Trauma (blunt or penetrating).
Vasculitis and vasculopathy:
- Buerger disease.
- Eosinophilic granulomatosis with angiitis.
- Fibromuscular dysplasia.
- Kawasaki disease.
- Polyarteritis nodosa.
- Rheumatoid vasculitis.
- SLE.
- Takayasu arteritis.

Volvulus.

COLOR CHANGES, CUTANEOUS[78]

ICD-10CM # L81.9 Disorder of pigmentation, unspecified

BROWN

Generalized: pituitary, adrenal, liver disease, ACTH-producing tumor (e.g., oat cell lung carcinoma).
Localized: nevi, neurofibromatosis.

WHITE

Generalized: albinism.
Localized: vitiligo, Raynaud phenomenon.

RED (ERYTHEMA)

Generalized: fever, polycythemia, urticaria, viral exanthems.
Localized: inflammation, infection, Raynaud phenomenon.

YELLOW

Generalized: liver disease, chronic renal disease, anemia.
Generalized (except sclera): hypothyroidism, increased intake of vegetables containing carotene.
Localized: resolving hematoma, infection, peripheral vascular insufficiency.

BLUE

Lips, mouth, nail beds: cardiovascular and pulmonary diseases, Raynaud phenomenon.

COMA

ICD-10CM # R40.20 Unspecified coma

Vascular: hemorrhage, thrombosis, embolism.
CNS infections: meningitis, encephalitis, cerebral abscess.
Cerebral neoplasms with herniation.
Head injury: subdural hematoma, cerebral concussion, cerebral contusion.
Drugs: narcotics, sedatives, hypnotics.
Ingestion or inhalation of toxins: CO, alcohol, lead.
Metabolic disturbances.
Hypoxia.
Acid-base disorders.
Hypoglycemia, hyperglycemia.
Hepatic failure.
Electrolyte disorders.
Uremia.
Hypothyroidism.
Hypothermia, hyperthermia.
Hypotension, malignant hypertension.
Postictal.

COMA, NORMAL COMPUTED TOMOGRAPHY[3]

ICD-10CM # R40.20 Unspecified coma

MENINGEAL DISORDERS

Subarachnoid hemorrhage (uncommon).
Bacterial meningitis.
Encephalitis.
Subdural empyema.

EXOGENOUS TOXINS

Sedative drugs and barbiturates.
Anesthetics and γ-hydroxybutyrate.[12]
Alcohols.
Stimulants:
- Phencyclidines.[13]
- Cocaine and amphetamines.[14]

Psychotropic drugs:
- Cyclic antidepressants.
- Phenothiazines.
- Lithium.

Anticonvulsants.
Opioids.
Clonidine.[15]
Penicillins.
Salicylates.
Anticholinergics.
Carbon monoxide, cyanide, and methemoglobinemia.

ENDOGENOUS TOXINS/ DEFICIENCIES/DERANGEMENTS

Hypoxia and ischemia.
Hypoglycemia.
Hypercalcemia.
Osmolar:
- Hyperglycemia.
- Hyponatremia.
- Hypernatremia.

Organ system failure:
- Hepatic encephalopathy.
- Uremic encephalopathy.
- Pulmonary insufficiency (carbon dioxide narcosis).

SEIZURES

Prolonged postictal state.
Spike-wave stupor.

HYPOTHERMIA OR HYPERTHERMIA

Brain stem ischemia.
Basilar artery stroke.
Brain stem or cerebellar hemorrhage.
Conversion or malingering.

[12] General anesthetic, similar to g-aminobutyric acid; recreational drug and body building aid. Rapid onset, rapid recovery often with myoclonic jerking and confusion. Deep coma (2–3 hr; Glasgow Coma Scale = 3) with maintenance of vital signs.
[13] Coma associated with cholinergic signs: lacrimation, salivation, bronchorrhea, and hyperthermia.
[14] Coma after seizures or status (i.e., a prolonged postictal state).
[15] An antihypertensive agent active through the opiate receptor system; frequent overdose when used to treat narcotic withdrawal.

COMA, PEDIATRIC POPULATION[72]

ICD-10CM # R40.20 Unspecified coma

ANOXIA

Birth asphyxia.
Carbon monoxide poisoning.
Croup/epiglottitis.
Meconium aspiration.

INFECTION

Hemolysis.
Blood loss.
Hydrops fetalis.
Infection.
Meningoencephalitis.
Sepsis.
Postimmunization encephalitis.

INCREASED INTRACRANIAL PRESSURE

Anoxia.
Inborn metabolic errors.
Toxic encephalopathy.
Reye syndrome.
Head trauma/intracranial bleed.
Hydrocephalus.
Posterior fossa tumors.

HYPERTENSIVE ENCEPHALOPATHY

Coarctation of aorta.
Nephritis.
Vasculitis.
Pheochromocytoma.

ISCHEMIA

Hypoplastic left heart.
Shunting lesions.
Aortic stenosis.
Cardiovascular collapse (any cause).

PURPURIC CAUSES

Disseminated intravascular coagulation.
Hemolytic-uremic syndrome.
Leukemia.
Thrombotic purpura.

HYPERCAPNIA

Cystic fibrosis.
Bronchopulmonary dysplasia.
Congenital lung anomalies.

NEOPLASM

Medulloblastoma.
Glioma of brain stem.
Posterior fossa tumors.

DRUGS/TOXINS

Maternal sedation.
Alcohol.
Any drug.
Lead.
Salicylism.
Arsenic.
Pesticides.

ELECTROLYTE ABNORMALITIES

Hypernatremia (diarrhea, dehydration, salt poisoning).
Hyponatremia (SIADH, androgenital syndrome, gastroenteritis).
Hyperkalemia (renal failure, salicylism, androgenitalism).
Hypokalemia (diarrhea, hyperaldosteronism, salicylism, DKA).
Hypocalcemia (vitamin D deficiency, hyperparathyroidism).
Severe acidosis (sepsis, cold injury, salicylism, DKA).

HYPOGLYCEMIA

Birth injury or stress.
Diabetes.
Alcohol.
Salicylism.
Hyperinsulinemia.
Iatrogenic.

POSTSEIZURE

Renal Causes
Nephritis.
Hypoplastic kidneys.
Hepatic Causes
Acute hepatitis.
Fulminant hepatic failure.
Inborn metabolic errors.
Bile duct atresia.

COMPRESSION SYNDROMES, NEUROVASCULAR CAUSES[69]

ICD-10CM #
- M47.016 Anterior spinal artery compression syndromes, lumbar region
- M47.019 Anterior spinal artery compression syndromes, site unspecified
- M47.013 Anterior spinal artery compression syndromes, cervicothoracic region
- M47.021 Vertebral artery compression syndromes, occipito-atlanto-axial region
- M47.022 Vertebral artery compression syndromes, cervical region

Anatomic
Potential sites of neurovascular compression:
- Interscalene triangle.
- Costoclavicular space.
- Subcoracoid area.

Congenital
Cervical rib and its fascial remnants.
Rudimentary first thoracic rib.
Scalene muscles:
- Anterior.
- Middle.
- Minimus.

Adventitious fibrous bands.

Bifid clavicle or first rib.
Exostosis of first thoracic rib.
Enlarged transverse process of C7.
Omohyoid muscle.
Anomalous course of transverse cervical artery.
Abnormal lateral insertion of costoclavicular ligament.
Flat clavicle.
Traumatic
Fracture of clavicle.
Dislocation of head of humerus.
Crushing injury to upper thorax.
Sudden, unaccustomed muscular efforts involving shoulder girdle muscles.
Cervical spondylosis and injuries to cervical spine.
Atherosclerosis.

CONGESTIVE HEART FAILURE AND CARDIOMYOPATHY[3]

ICD-10CM # I50.9 Heart failure, unspecified
I42.7 Cardiomyopathy due to drug and external agent

CAUSES OF CONGESTIVE HEART FAILURE AND CARDIOMYOPATHY

Coronary Artery Disease
Acute ischemia.
Myocardial infarction.
Ischemic cardiomyopathy with hibernating myocardium.
Idiopathic
Idiopathic dilated cardiomyopathy.
Idiopathic restrictive cardiomyopathy.
Peripartum.
Pressure Overload
Hypertension.
Aortic stenosis.
Volume Overload
Mitral regurgitation.
Aortic insufficiency.
Anemia.
Atrioventricular fistula.
Toxins
Ethanol.
Cocaine.
Doxorubicin (Adriamycin).
Methamphetamine.
Metabolic-Endocrine
Thiamine deficiency.
Diabetes.
Hemochromatosis.
Thyrotoxicosis.
Obesity.
Infiltrative
Amyloidosis.
Inflammatory
Viral myocarditis.
Hereditary
Hypertrophic.
Dilated.

Genetic bases for these cardiomyopathies have been identified in a large number of individual patients and families. Most of the mutations have been found in cardiac contractile or structural proteins.

CONGESTIVE HEART FAILURE, INFANT[1]

ICD-10CM # I05.9 Heart failure, unspecified

Critical coarctation of the aorta.
Interrupted aortic arch.
Congenital aortic stenosis.
Hypoplastic left heart syndrome.
Large ventricular septal defect.
Truncus arteriosus.
Unrecognized supraventricular tachycardia.
Cardiac tamponade.
Myocarditis.

CONJUNCTIVAL NEOPLASM

ICD-10CM # Varies with specific diagnosis

MALIGNANT

Squamous cell carcinoma.
Melanoma.
Sebaceous carcinoma.
Kaposi sarcoma.
Metastatic neoplasms.

BENIGN

Melanocytic nevus.
Squamous papilloma.
Hemangioma.
Lymphangioma.
Myxoma.

CONSCIOUSNESS IMPAIRMENT, ACUTE, IN CRITICALLY ILL PATIENT

ICD-10CM # F05.9 Delirium, unspecified

GENERAL CAUSES OF ACUTELY IMPAIRED CONSCIOUSNESS IN THE CRITICALLY ILL

Infection
Sepsis encephalopathy.
CNS infection.
Drugs
Narcotics.
Benzodiazepines.
Anticholinergics.
Anticonvulsants.
Tricyclic antidepressants.
Selective serotonin uptake inhibitors.
Phenothiazines.
Steroids.
Immunosuppressants (cyclosporine, FK-506, OKT3).
Anesthetics.
Electrolyte and Acid-Base Disturbances
Hyponatremia.
Hypernatremia.
Hypercalcemia.
Hypermagnesemia.
Severe acidemia and alkalemia.
Organ System Failure
Shock.
Renal failure.
Hepatic failure.
Pancreatitis.
Respiratory failure (hypoxia, hypercapnia).
Endocrine Disorders
Hypoglycemia.
Hyperglycemia.
Hypothyroidism.
Hyperthyroidism.
Pituitary apoplexy.
Drug Withdrawal
Alcohol.
Opiates.
Barbiturates.
Benzodiazepines.
Vascular Causes
Shock.
Hypotension.
Hypertensive encephalopathy.
CNS vasculitis.
Cerebral venous sinus thrombosis.
Central Nervous System Disorders
Hemorrhage.
Stroke.
Brain edema.
Hydrocephalus.
Increased intracranial pressure.
Meningitis.
Ventriculitis.
Brain abscess.
Subdural empyema.
Seizures.
Vasculitis.
Seizures
Convulsive and nonconvulsive status epilepticus.
Miscellaneous
Fat embolism syndrome.
Neuroleptic malignant syndrome.
Thiamine deficiency (Wernicke encephalopathy).
Psychogenic unresponsiveness.

CONSTIPATION

ICD-10CM # K59.00 Constipation, unspecified

Intestinal obstruction.
Fecal impaction.
Diverticular disease.
GI neoplasm.
Strangulated femoral hernia.
Gallstone ileus.
Tuberculous stricture.
Adhesions.
Ameboma.
Volvulus.
Intussusception.
Inflammatory bowel disease.
Hematoma of bowel wall, secondary to trauma or anticoagulants.
Poor dietary habits: insufficient bulk in diet, inadequate fluid intake.
Change from daily routine: travel, hospital admission, physical inactivity.
Acute abdominal conditions: renal colic, salpingitis, biliary colic, appendicitis, ischemia.
Hypercalcemia or hypokalemia, uremia.
Irritable bowel syndrome, pregnancy, anorexia nervosa, depression.
Painful anal conditions: hemorrhoids, fissure, stricture.
Decreased intestinal peristalsis: old age, spinal cord injuries, myxedema, diabetes, multiple

sclerosis, Parkinsonism and other neurologic diseases.
Drugs: codeine, morphine, antacids with aluminum, verapamil, anticonvulsants, anticholinergics, disopyramide, cholestyramine, alosetron, iron supplements.
Hirschsprung disease, meconium ileus, congenital atresia in infants.

CONSTIPATION, ADULT PATIENT[86]

ICD-10CM # K59.00 Constipation, unspecified

NO GROSS STRUCTURAL ABNORMALITY

Inadequate fiber intake.
Irritable bowel syndrome (associated with abdominal pain) or functional constipation.
Idiopathic slow-transit constipation.
"Obstructed defecation" pelvic floor dysfunction (or dyssynergia).

STRUCTURAL DISORDERS

Anal fissure, infection, or stenosis.
Colon cancer or stricture.
Aganglionosis and/or abnormal myenteric plexus:
  Hirschsprung disease.
  Chagas disease.
  Neuropathic pseudoobstruction.
Abnormal colonic muscle:
  Myopathy.
  Dystrophia myotonica.
  Systemic sclerosis.
Idiopathic megarectum and/or megacolon.
Proximal megacolon.

NEUROLOGIC CAUSES

Diabetic autonomic neuropathy.
Damage to the sacral parasympathetic outflow.
Spinal cord damage or disease (e.g., multiple sclerosis).
Parkinson disease.
Blunting of consciousness, mental retardation, psychosis.
Pain induced by straining (e.g., sciatic nerve compression).

ENDOCRINE OR METABOLIC CAUSES

Hypothyroidism.
Hypercalcemia.
Porphyria.
Pregnancy.

PSYCHOLOGIC DISORDERS

Depression.
Anorexia nervosa.
Denied bowel habit.
Drug side effects.

CONSTIPATION, PEDIATRIC PATIENT[54]

ICD-10CM # K59.00 Constipation

Nonorganic (Functional)—Retentive

Anatomic
Anal stenosis, atresia with fistula.
Imperforate anus.
Anteriorly displaced anus.
Intestinal stricture (postnecrotizing enterocolitis).
Anal stricture.
Abnormal Musculature
Prune-belly syndrome.
Gastroschisis.
Down syndrome.
Muscular dystrophy.
Intestinal Nerve or Muscle Abnormalities
Hirschsprung disease.
Pseudoobstruction (visceral myopathy or neuropathy).
Intestinal neuronal dysplasia.
Spinal cord lesions.
Tethered cord.
Autonomic neuropathy.
Spinal cord trauma.
Spina bifida.
Chagas disease.
Drugs
Anticholinergics.
Narcotics.
Methylphenidate.
Phenytoin.
Antidepressants.
Chemotherapeutic agents (vincristine).
Pancreatic enzymes (fibrosing colonopathy).
Lead, arsenic, mercury.
Vitamin D intoxication.
Calcium channel blocking agents.
Metabolic Disorders
Hypokalemia.
Hypercalcemia.
Hypothyroidism.
Diabetes mellitus, diabetes insipidus.
Porphyria.
Intestinal Disorders
Celiac disease.
Cow's milk protein intolerance.
Cystic fibrosis (meconium ileus equivalent).
Inflammatory bowel disease (stricture).
Tumor.
Connective tissue disorders.
Systemic lupus erythematosus.
Scleroderma.
Psychiatric Diagnosis
Anorexia nervosa.

COPD DECOMPENSATION[60]

ICD-10CM # J44.1 Chronic obstructive pulmonary distress with acute exacerbation

CAUSES OF ACUTE DECOMPENSATION IN THE PATIENT WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Acute Exacerbations
Infectious
Viral.
Rhinovirus, respiratory syncytial virus, coronavirus, influenza virus.
Bacterial.
Haemophilus influenzae, Streptococcus pneumoniae, Moraxella (Branhamella) catarrhalis, Pseudomonas aeruginosa.
Atypical bacteria.
Chlamydia pneumoniae, Legionella.
Air Pollution
Nitrogen dioxide.
Ozone.
Particulates, dust.
Other Critical Events
Pneumothorax.
Pulmonary embolism.
Lobar atelectasis.
Congestive heart failure.
Pneumonia.
Pulmonary compression (e.g., obesity, ascites, gastric distention, pleural effusion).
Trauma (e.g., rib fractures, pulmonary contusion).
Neuromuscular and metabolic disorders.
Unrelated treatable chronic pulmonary disease (bronchiectasis, tuberculosis, sarcoidosis).
Noncompliance with prescribed treatment regimens.
Iatrogenic:
  Inadequate therapy.
  Inappropriate therapy (e.g., deleterious drugs).

CORNEAL SENSATION, DECREASED

ICD-10CM # H18.899 Other specified disorders of cornea, unspecified eye

Herpes (simplex, zoster).
Contact lens wear.
Topical agents (NSAIDs, anesthetics, beta-blockers).
Diabetes.
Eye trauma.
Postsurgery.

COUGH

ICD-10CM # R05 Cough

Infectious process (viral, bacterial).
Postinfectious.
"Smoker's cough."
Rhinitis (allergic, vasomotor, postinfectious).
Asthma.
Exposure to irritants (noxious fumes, smoke, cold air).
Drug-induced (especially ACE inhibitors, beta-blockers).
GERD.
Interstitial lung disease.
Lung neoplasms.
Lymphomas, mediastinal neoplasms.
Bronchiectasis.
Cardiac (CHF, pulmonary edema, mitral stenosis, pericardial inflammation).
Recurrent aspiration.
Inflammation of larynx, pleura, diaphragm, mediastinum.
Cystic fibrosis.
Anxiety.
Other: pulmonary embolism, foreign body inhalation, aortic aneurysm, Zenker diverticulum, osteophytes, substernal thyroid, thyroiditis, PMR.

COUGH, CHRONIC, ADULT PATIENT[2]

ICD-10CM # R05 Cough

CAUSES OF CHRONIC COUGH IN ADULTS

Intrathoracic Causes

Lungs and Airways

Asthma.
Nonasthmatic eosinophilic bronchitis.
Chronic bronchitis.
Bronchiectasis.
ACEIs.
Inhaled medications.
Chronic exposure to environmental and occupational irritants.
Bronchogenic and metastatic carcinoma.
Bronchial carcinoid.
Foreign body or endobronchial suture.
Broncholith.
Infectious and noninfectious bronchiolitis.
Chronic infectious pneumonias (e.g., bacterial, tuberculous, fungal, parasitic).
Chronic infectious tracheobronchitis (as in tuberculosis or aspergillosis).
Chronic interstitial lung disease (e.g., sarcoidosis, HSP, IPF, asbestosis).
Pulmonary vasculitis (as in granulomatosis with polyangiitis).
Sjögren syndrome with xerotrachea.
Relapsing polychondritis.

Pleura

Chronic effusion.

Diaphragm

Transvenous pacemaker stimulation.

Mediastinum

Neural tumors.
Thymoma.
Teratoma.
Lymphoma.
Metastatic lymphadenopathy.
Intrathoracic goiter.
Bronchogenic cyst.

Cardiovascular

Mitral stenosis.
Left ventricular failure.
Pulmonary thromboembolism.
Enlarged left atrium.
Vascular ring.
Aberrant innominate artery.
Aortic aneurysm.
Pericardial stimulation by transvenous pacemaker.

Extrathoracic Causes

Head and Neck

Rhinitis and sinusitis.
Nasal polyps.
Rhinolith.
Oropharyngeal dysphagia.
Laryngeal disorders (e.g., vocal fold dysfunction, laryngomalacia).
Postviral vagal neuropathy.
Recurrent aspiration.
Elongated uvula.
Chronically infected tonsils.
Neurilemmoma of vagus nerve.
Neuroma of internal laryngeal nerve.
Ascending palatine artery aneurysm.
Osteophytes of cervical spine.
Mammomanogamus (Syngamus) laryngeus infection.
Thyroiditis.

Upper Gastrointestinal

Gastroesophageal reflux disease.
Esophageal cyst or diverticulum.
Tracheoesophageal fistula.

Central Nervous System

Psychogenic or habit cough.
Tic disorders.
Gilles de la Tourette syndrome.

ACEI, Angiotensin-converting enzyme inhibitor; *HSP,* hypersensitivity pneumonitis; *IPF,* idiopathic pulmonary fibrosis.

COUGH, CHRONIC, PEDIATRIC PATIENT[54]

ICD-10CM # R05 Cough

DIFFERENTIAL DIAGNOSIS OF RECURRENT AND PERSISTENT COUGH IN CHILDREN

Recurrent Cough

Reactive airway disease (asthma).
Drainage from upper airways.
Aspiration.
Frequently recurring respiratory tract infections in immunocompetent or immunodeficient patients.
Symptomatic Chiari malformation.
Idiopathic pulmonary hemosiderosis.
Hypersensitivity (allergic) pneumonitis.

Persistent Cough

Hypersensitivity of cough receptors after infection.
Reactive airway disease (asthma).
Chronic sinusitis.
Chronic rhinitis (allergic or nonallergic).
Bronchitis or tracheitis caused by infection or smoke exposure.
Bronchiectasis, including cystic fibrosis, primary ciliary dyskinesia, immunodeficiency.
Habit cough.
Foreign-body aspiration.
Recurrent aspiration owing to pharyngeal incompetence, tracheolaryngoesophageal cleft or tracheoesophageal fistula.
Gastroesophageal reflux, with or without aspiration.
Pertussis.
Extrinsic compression of the tracheobronchial tract (vascular ring, neoplasm, lymph node, lung cyst).
Tracheomalacia, bronchomalacia.
Endobronchial or endotracheal tumors.
Endobronchial tuberculosis.
Hypersensitivity pneumonitis.
Fungal infections.
Inhaled irritants, including tobacco smoke.
Irritation of external auditory canal.
Angiotensin-converting enzyme inhibitors.

CUTANEOUS INFECTIONS, ATHLETES

ICD-10CM # L08.9 Local infection of the skin and subcutaneous tissue, unspecified

Tinea pedis.
Tinea cruris.
Molluscum contagiosum.
Herpes simplex.
Verruca vulgaris.
Folliculitis.
Impetigo.
Furuncles.
Otitis externa.
Erythrasma.

CYANOSIS[7]

ICD-10CM # R23.0 Cyanosis

DIFFERENTIAL DIAGNOSIS OF CYANOSIS

Peripheral Cyanosis

Low cardiac output states

Shock.
Left ventricular failure.
Hypovolemia.

Environmental exposure (cold)

Air or water.

Arterial occlusion

Thrombosis.
Embolism.
Vasospasm (Raynaud phenomenon).
Peripheral vascular disease.

Venous obstruction

Redistribution of blood flow from extremities

Central Cyanosis

Decreased arterial oxygen saturation

High altitude (>8000 ft).
Impaired pulmonary function:
- Hypoventilation.
- Impaired oxygen diffusion.
- Ventilation-perfusion mismatching:
  - Pulmonary embolism.
  - Acute respiratory distress syndrome.
  - Pulmonary hypertension.
- Respiratory compromise:
  - Upper airway obstruction.
  - Pneumonia.
  - Diaphragmatic hernia.
  - Tension pneumothorax.
  - Polycythemia.

Anatomic Shunts

Pulmonary arteriovenous fistulae and intrapulmonary shunts.
Cerebral, hepatic, peripheral arteriovenous fistulae.
Cyanotic congenital heart disease:
- Endocardial cushion defects.
- Ventricular septal defects.
- Coarctation of aorta.
- Tetralogy of Fallot.
- Total anomalous pulmonary venous drainage.
- Hypoplastic left ventricle.
- Pulmonary vein stenosis.
- Tricuspid atresia and anomalies.
- Premature closure of foramen ovale.
- Dextrocardia.
- Pulmonary stenosis of atrial septal defect.
- Patent ductus arteriosus with reversed shunt.

Abnormal Hemoglobin

Methemoglobinemia:
- Hereditary.
- Acquired.

Sulfhemoglobinemia.
Mutant hemoglobin with low oxygen affinity (e.g., hemoglobin Kansas).

CYANOSIS, CENTRAL, SECONDARY TO CARDIAC DEFECT [95]

ICD-10CM # R23.0 Cyanosis

Transposition of the great arteries.
Tetralogy of Fallot.
Tricuspid atresia.
Truncus arteriosus.
Total anomalous pulmonary venous return.
Ebstein anomaly.
Eisenmenger physiology.
Critical pulmonary stenosis or atresia.
Functionally single ventricle.

Note 5 Ts and 2 Es.

CYANOSIS, NEONATAL [1]

ICD-10CM # R23.0 Cyanosis

RESPIRATORY

Upper Airway
Choanal atresia.
Macroglossia.
Glossoptosis (secondary to micrognathia).
Laryngomalacia.
Laryngeal web or cyst.
Vascular anomalies (e.g., cystic hygromas, rings).
Subglottic stenosis (commonly secondary to intubation).
Foreign body.
Lower Airway
Pneumonia.
Bronchiolitis.
Pulmonary edema.
Atelectasis.
Bronchopulmonary dysplasia.

SYSTEMIC

Sepsis.
Trauma.
Poisons.

CARDIAC

Cyanotic congenital heart diseases.
Transposition of the great vessels (most common neonatal).
Tetralogy of Fallot.
Truncus arteriosus.
Tricuspid atresia.
Total anomalous pulmonary venous return.
Ebstein anomaly.
GI.
Gastroesophageal reflux.

NEUROLOGIC

Seizures.
Central hypoventilation syndrome (Ondine curse).
Spinal muscular atrophy type I (Werdnig-Hoffmann).
Botulism.
Congenital myopathies.

HEMATOLOGIC

Methemoglobinemia.

CYTOPENIAS, OLDER ADULTS [46]

ICD-10CM # D46.A Refractory cytopenia with multilineage dysplasia

Cytopenia of one or more lineages.
Hematologic neoplasm.
Vitamin B_{12} deficiency.
Autoimmune disorder.
Consumptive coagulopathy.
Systemic inflammation.
Alcohol.
Splenomegaly.
Thyroid dysfunction.
Human immunodeficiency virus.

DAYTIME SLEEPINESS

ICD-10CM # R53.82 Chronic fatigue, unspecified

Sleep deprivation.
Medication induced (e.g., benzodiazepines, beta-blockers, narcotics, sedative antidepressants, gabapentin).
Depression.
Obstructive sleep apnea.
Medical illness (e.g., severe anemia, hypothyroidism, COPD, hepatic failure, renal insufficiency, CHF, electrolyte disturbances).
Circadian rhythm abnormalities (e.g., jet lag, shift work sleep disorder).
Restless legs syndrome.
Posttrauma.
Narcolepsy.
Neurologic disorders (e.g., neurodegenerative disorders; parkinsonism; multiple sclerosis; lesions affecting thalamus, hypothalamus, or brain stem).

DELAYED PASSAGE OF MECONIUM [36]

ICD-10CM # P76.0 Meconium plug syndrome

Ileal atresia.
Meconium ileus.
Functional immaturity of the colon.
Colon atresia.
Anorectal malformations.
Hirschsprung disease.
Megacystis-microcolon-intestinal hypoperistalsis syndrome.
Extrinsic compression of the distal bowel by a mass lesion.
  Mesenteric cyst.
  Enteric duplication cyst.
Paralytic ileus, sepsis, drugs, and metabolic upset.

DELIRIUM [58]

ICD-10CM # R40.0 Somnolence
R40.1 Stupor
F05 Delirium due to known physiological condition

PHARMACOLOGIC AGENTS

Anxiolytics (benzodiazepines).
Antidepressants (e.g., amitriptyline, doxepin, imipramine).
Cardiovascular agents (e.g., methyldopa, digitalis, reserpine, propranolol, procainamide, captopril, disopyramide).
Antihistamine.
Cimetidine.
Corticosteroids.
Antineoplastics.
Drugs of abuse (alcohol, cannabis, amphetamines, cocaine, hallucinogens, opioids, sedative-hypnotics, phencyclidine).

METABOLIC DISORDERS

Hypercalcemia.
Hypercarbia.
Hypoglycemia.
Hyponatremia.
Hypoxia.

INFLAMMATORY DISORDERS

Sarcoidosis.
SLE.
Giant cell arteritis.

ORGAN FAILURE

Hepatic encephalopathy.
Uremia.

NEUROLOGIC DISORDERS

Alzheimer disease.
CVA.
Encephalitis (including HIV).
Encephalopathies.
Epilepsy.
Huntington disease.
Multiple sclerosis.
Neoplasms.
Normal-pressure hydrocephalus.
Parkinson disease.
Pick disease.
Wilson disease.

ENDOCRINE DISORDERS

Addison disease.
Cushing syndrome.
Panhypopituitarism.
Parathyroid disease.
Postpartum psychosis.
Recurrent menstrual psychosis.
Sydenham chorea.
Thyroid disease.

DEFICIENCY STATES

Niacin.
Thiamine, vitamin B_{12}, and folate.

DELIRIUM AND AGITATION, DRUG-INDUCED

ICD-10CM # F05.9 Delirium, unspecified

COMMONLY USED DRUGS ASSOCIATED WITH DELIRIUM AND AGITATION

Benzodiazepines.
Opiates (especially meperidine).
Anticholinergics.
Antihistamines.
H_2 blockers.

CYANOSIS, CENTRAL, SECONDARY TO CARDIAC DEFECT [95]

ICD-10CM # R23.0 Cyanosis

Transposition of the great arteries.
Tetralogy of Fallot.
Tricuspid atresia.
Truncus arteriosus.
Total anomalous pulmonary venous return.
Ebstein anomaly.
Eisenmenger physiology.
Critical pulmonary stenosis or atresia.
Functionally single ventricle.

Note 5 Ts and 2 Es.

CYANOSIS, NEONATAL [1]

ICD-10CM # R23.0 Cyanosis

RESPIRATORY

Upper Airway
Choanal atresia.
Macroglossia.
Glossoptosis (secondary to micrognathia).
Laryngomalacia.
Laryngeal web or cyst.
Vascular anomalies (e.g., cystic hygromas, rings).
Subglottic stenosis (commonly secondary to intubation).
Foreign body.
Lower Airway
Pneumonia.
Bronchiolitis.
Pulmonary edema.
Atelectasis.
Bronchopulmonary dysplasia.

SYSTEMIC

Sepsis.
Trauma.
Poisons.

CARDIAC

Cyanotic congenital heart diseases.
Transposition of the great vessels (most common neonatal).
Tetralogy of Fallot.
Truncus arteriosus.
Tricuspid atresia.
Total anomalous pulmonary venous return.
Ebstein anomaly.
GI.
Gastroesophageal reflux.

NEUROLOGIC

Seizures.
Central hypoventilation syndrome (Ondine curse).
Spinal muscular atrophy type I (Werdnig-Hoffmann).
Botulism.
Congenital myopathies.

HEMATOLOGIC

Methemoglobinemia.

CYTOPENIAS, OLDER ADULTS [46]

ICD-10CM # D46.A Refractory cytopenia with multilineage dysplasia

Cytopenia of one or more lineages.
Hematologic neoplasm.
Vitamin B_{12} deficiency.
Autoimmune disorder.
Consumptive coagulopathy.
Systemic inflammation.
Alcohol.
Splenomegaly.
Thyroid dysfunction.
Human immunodeficiency virus.

DAYTIME SLEEPINESS

ICD-10CM # R53.82 Chronic fatigue, unspecified

Sleep deprivation.
Medication induced (e.g., benzodiazepines, beta-blockers, narcotics, sedative antidepressants, gabapentin).
Depression.
Obstructive sleep apnea.
Medical illness (e.g., severe anemia, hypothyroidism, COPD, hepatic failure, renal insufficiency, CHF, electrolyte disturbances).
Circadian rhythm abnormalities (e.g., jet lag, shift work sleep disorder).
Restless legs syndrome.
Posttrauma.
Narcolepsy.
Neurologic disorders (e.g., neurodegenerative disorders; parkinsonism; multiple sclerosis; lesions affecting thalamus, hypothalamus, or brain stem).

DELAYED PASSAGE OF MECONIUM [36]

ICD-10CM # P76.0 Meconium plug syndrome

Ileal atresia.
Meconium ileus.
Functional immaturity of the colon.
Colon atresia.
Anorectal malformations.
Hirschsprung disease.
Megacystis-microcolon-intestinal hypoperistalsis syndrome.
Extrinsic compression of the distal bowel by a mass lesion.
  Mesenteric cyst.
  Enteric duplication cyst.
Paralytic ileus, sepsis, drugs, and metabolic upset.

DELIRIUM [58]

ICD-10CM # R40.0 Somnolence
R40.1 Stupor
F05 Delirium due to known physiological condition

PHARMACOLOGIC AGENTS

Anxiolytics (benzodiazepines).
Antidepressants (e.g., amitriptyline, doxepin, imipramine).

Encephalitis (including HIV).
Encephalopathies.
Epilepsy.
Huntington disease.
Multiple sclerosis.
Neoplasms.
Normal-pressure hydrocephalus.
Parkinson disease.
Pick disease.
Wilson disease.

ENDOCRINE DISORDERS

Addison disease.
Cushing syndrome.
Panhypopituitarism.
Parathyroid disease.
Postpartum psychosis.
Recurrent menstrual psychosis.
Sydenham chorea.
Thyroid disease.

DEFICIENCY STATES

Niacin.
Thiamine, vitamin B_{12}, and folate.

DELIRIUM AND AGITATION, DRUG-INDUCED

ICD-10CM # F05.9 Delirium, unspecified

COMMONLY USED DRUGS ASSOCIATED WITH DELIRIUM AND AGITATION

Benzodiazepines.
Opiates (especially meperidine).
Anticholinergics.
Antihistamines.
H_2 blockers.

Antibiotics.
Corticosteroids.
Metoclopramide.

DELIRIUM, AGITATED[7]

ICD-10CM #		
	F05	Delirium due to known physiological condition

Metabolic causes:
- Electrolyte abnormalities.
- Hypoglycemia.
- Hypoxia.
- Uremia/hyperammonemia.

Structural lesions of the CNS:
- Trauma.
- Stroke.
- Hemorrhage.
- Mass.

Endocrine disease:
- Thyrotoxicosis.

Infections:
- Bacterial/viral meningitis/encephalitis.

Toxicologic causes:
- Sympathomimetic/stimulants.
- Cocaine.
- Amphetamines and derivatives.
- Caffeine.
- Phencyclidine/ketamine.
- Anticholinergics.
- Serotonin syndrome.
- Sedative-hypnotic withdrawal.

Heatstroke.
Postictal state.

CNS, Central nervous system.

DELIRIUM, DIALYSIS PATIENT[58]

ICD-10CM #		
	F05	Delirium due to known physiological condition
	F06.8	Other specified mental disorders due to known physiological condition

STRUCTURAL

Cerebrovascular accident (particularly hemorrhage).
Subdural hematoma.
Intracerebral abscess.
Brain tumor.

METABOLIC

Disequilibrium syndrome.
Uremia.
Drug effects.
Meningitis.
Hypertensive encephalopathy.
Hypotension.
Postictal state.
Hypernatremia or hyponatremia.
Hypercalcemia.
Hypermagnesemia.
Hypoglycemia.
Severe hyperglycemia.
Hypoxemia.
Dialysis dementia.

DEMENTIA, ADOLESCENT PATIENT[51]

ICD-10CM #		
	F03	Unspecified dementia
	F03.90	Unspecified dementia without behavioral disturbance

CAUSES OF DEMENTIA IN ADOLESCENTS

Autoimmune or inflammatory diseases:
- Paraneoplastic syndromes, including NMDA antibody encephalitis.
- Vasculitis.

Cerebral and noncerebral neoplasms:
- Chemotherapy (intrathecal).
- Radiotherapy treatment.

Drug, inhalant, and alcohol abuse, including overdose.
Head trauma, including child abuse.
Infections:
- HIV-associated dementia.
- Variant Creutzfeldt–Jakob disease (vCJD).
- Subacute sclerosing panencephalitis (SSPE).

Metabolic abnormalities:
- Adrenoleukodystrophy.
- Wilson disease.

Neurodegenerative illnesses:
- Huntington disease.
- Metachromatic leukodystrophy.
- Other rare, usually genetically transmitted, illnesses.

DEMYELINATING DISEASES[93]

ICD-10CM #		
	G37.9	Demyelinating disease of central nervous system, unspecified

MULTIPLE SCLEROSIS

Relapsing and chronic progressive forms.
Acute multiple sclerosis.
Neuromyelitis optica (Devic disease).

DIFFUSE CEREBRAL SCLEROSIS

Schilder encephalitis periaxialis diffusa.
Baló concentric sclerosis.

ACUTE DISSEMINATED ENCEPHALOMYELITIS

After measles, chickenpox, rubella, influenza, mumps.
After rabies or smallpox vaccination.

NECROTIZING HEMORRHAGIC ENCEPHALITIS

Hemorrhagic leukoencephalitis.

LEUKODYSTROPHIES

Krabbe globoid leukodystrophy.
Metachromatic leukodystrophy.
Adrenoleukodystrophy.
Adrenomyeloneuropathy.
Pelizaeus-Merzbacher leukodystrophy.
Canavan disease.
Alexander disease.

DIAPHRAGM ELEVATION, BILATERAL, SYMMETRICAL[36]

ICD-10CM #		
	J98.6	Disorders of diaphragm

CAUSES OF BILATERAL SYMMETRICAL ELEVATION OF THE DIAPHRAGM

Supine position.
Poor inspiration.
Obesity.
Pregnancy.
Abdominal distention (ascites, intestinal obstruction, abdominal mass).
Diffuse pulmonary fibrosis.
Lymphangitis carcinomatosa.
Disseminated lupus erythematosus.
Bilateral basal pulmonary emboli.
Painful conditions (after abdominal surgery).
Bilateral diaphragmatic paralysis.

DIAPHRAGM ELEVATION, UNILATERAL[36]

ICD-10CM #		
	J98.6	Disorders of diaphragm

CAUSES OF UNILATERAL ELEVATION OF THE DIAPHRAGM

Posture—lateral decubitus position (dependent side).
Gaseous distention of stomach or colon.
Dorsal scoliosis.
Pulmonary hypoplasia.
Pulmonary collapse.
Phrenic nerve palsy.
Eventration.
Pneumonia or pleurisy.
Pulmonary thromboembolism.
Rib fracture and other painful conditions.
Subphrenic infection.
Subphrenic mass.

DIARRHEA, ACUTE WATERY AND BLOODY[86]

ICD-10CM #		
	K52.2	Allergic and dietetic gastroenteritis and colitis
	K52.89	Other specified noninfective gastroenteritis and colitis
	R19.7	Diarrhea, unspecified

ACUTE WATERY DIARRHEA

GI infections:
- Protozoal (e.g., *Giardia*).
- Bacterial (e.g., enterotoxigenic *Escherichia coli,* cholera).
- Viral (e.g., rotavirus, Norwalk virus).

Drugs.
Toxins.
Dietary constituents (e.g., lactose intolerance).
Onset of chronic diarrheal illness.

ACUTE BLOODY DIARRHEA

Infectious colitis:
- Confluent proctocolitis (e.g., *Shigella, Campylobacter, Salmonella, Entamoeba histolytica*).
- Segmental colitis (e.g., *Campylobacter, Salmonella,* enteroinvasive *E. coli, Aeromonas, E. histolytica*).
- Drug-induced colitis (e.g., NSAIDs).
- Inflammatory bowel disease.
- Ischemic colitis (usually elderly patient with underlying heart disease or arrhythmias).
- Antibiotic-associated colitis.

DIARRHEA, CRITICALLY ILL PATIENT[79]

ICD-10CM # R19.7 Diarrhea, unspecified

COMMON CAUSES OF DIARRHEA IN CRITICALLY ILL PATIENTS

Medication
Antibiotics.
H2-recepter antagonists, antacids.
Drugs: significant amounts of sorbitol, magnesium, or hypertonic medications.
Laxative use (unintended).
Gastrointestinal Dysfunction
Gastric or small bowel resection.
Inflammatory bowel disease.
Pancreatic insufficiency.
Radiation enteritis.
Sprue.
Protein-losing gastroenteropathies.
Bowel impaction (paradoxic).
Malnutrition
Hypoproteinemia.
Micronutrient deficiencies.
Enteral Nutrition–Associated
Excessive feeding rate, concentration, volume, or osmolality.
Adaptation in malnourished patients or those whose GI tract has not been used recently.
Intolerance or allergy to feeding formula.
Infection
Clostridium difficile enterocolitis.
Opportunistic GI infection.
Significant amounts of contaminated feeding formula.
Altered GI flora.
Endocrine Dysfunction
Diabetes mellitus.
Hyperthyroidism.
Hypocortisolism.

DIARRHEA, INFECTIOUS[7]

ICD-10CM # A09 Infectious gastroenteritis and colitis, unspecified

ETIOLOGIC AGENTS OF INFECTIOUS DIARRHEA

Viral (60% of Cases)
Astrovirus.
Calicivirus.
Coronavirus.
Cytomegalovirus.[16]
Enteric adenovirus.
Hepatitis A through G.
Herpes simplex virus.
HIV enteropathy.
Norwalk-like agents.
Pararotavirus.
Norwalk virus.
Picornavirus.
Rotavirus.
Small round viruses.
Bacterial (20% of Cases)
Invasive
Aeromonas spp.
Campylobacter spp.
Clostridium difficile.
Enteroinvasive *E. coli.*
Mycobacterium spp.
Plesiomonas shigelloides.
Salmonella spp.
Shigella spp.
Vibrio fluvialis.
Vibrio parahaemolyticus.
Vibrio vulnificus.
Yersinia enterocolitica.
Yersinia pseudotuberculosis.
Toxigenic
Food poisoning with preformed toxins:
- *Bacillus cereus.*
- *Clostridium botulinum.*
- *Staphylococcus aureus.*

Toxin formation after colonization:
- *Aeromonas hydrophila.*
- *Clostridium perfringens.*
- Enterohemorrhagic *E. coli* O157:H7.
- Enterotoxigenic *E. coli.*
- *Klebsiella pneumoniae.*
- *Shigella* spp.
- *Vibrio cholerae.*
- **Other bacteria**

Parasitic (5% of Cases)
Protozoa
Balantidium coli.
Blastocystis hominis.
Cryptosporidium.
Cyclospora.
Dientamoeba fragilis.
Entamoeba histolytica.
Entamoeba polecki.
Enteromonas hominis.
Giardia lamblia.
Isospora belli.
Microsporidia.
Sarcocystis hominis.
Helminths
Angiostrongylus costaricense.
Anisakiasis.
Ascaris lumbricoides.
Diphyllobothrium latum.
Enterobius vermicularis.
Hookworms.
Schistosoma spp.
Strongyloides stercoralis.
Taenia spp.
Trichinella spiralis.
Trichuris trichiura.

[16] Associated with fever, abdominal pain, and fecal red blood cells or white blood cells. % indicates the estimated contribution to total cases.

DIARRHEA, NONINFECTIOUS[7]

ICD-10CM # K59.1 Functional diarrhea

CAUSES OF NONINFECTIOUS DIARRHEA

Toxins
Drugs
ACE inhibitors.
Alprazolam.
Antacids (Mg).
Antibiotics.
Antidepressants.
Antiepileptic drugs.
Antihypertensives.
Antiparkinson drugs.
Beta-blockers.
Caffeine.
Cardiac antiarrhythmics.
Chemotherapy agents.
Cholesterol-lowering drugs.
Cholinergic agents.
Cholinesterase inhibitors.
Colchicine.
Digitalis.
Diuretics.
Flurouracil.
Fluoxetine.
Histamine H_2-receptor antagonists.
Hydralazine.
Lactulose.
Laxatives/cathartics.
Levodopa.
Lithium.
NSAIDs.
Neomycin.
Podophyllin.
Procainamide.
Prostaglandins.
Quinidine.
Ricinoleic acid.
Theophylline.
Thyroid hormone.
Valproic acid.
Dietetic foods
Mannitol.
Sorbitol.
Xylitol.
Fish-associated toxins
Amnestic shellfish poisoning.
Ciguatera.
Echinoderms.
Neurotoxic shellfish poisoning.
Paralytic shellfish poisoning.
Scombroid.
Tetroton.
Plant-associated toxins
Herbal preparations.
Horse chestnut.
Mushrooms—*Amanita* spp.
Nicotine.
Other plant toxins:
- Pesticides—organophosphates.
- Pokeweed.
- Rhubarb.
- Miscellaneous:
  - Allergic reactions.
  - Carbon monoxide poisoning.

Ethanol.
Heavy metals.
Monosodium glutamate (MSG).
Opiate withdrawal.

Gastrointestinal Pathology

Appendicitis.
Autonomic dysfunction.
Bile acid malabsorption.
Blind loop.
Bowel obstruction.
Celiac disease.
Cirrhosis.
Defects in amino acid transport.
Diverticular disease.
Familial dysautonomia.
Fecal impaction.
Fecal incontinence.
GI bleed.
GI cancer.
Hirschsprung disease.
Inflammatory bowel disease (ulcerative colitis, Crohn disease).
Intussusception.
Irritable bowel syndrome.
Ischemic bowel.
Lactose/fructose intolerance.
Malabsorption syndromes.
Malrotation.
Postsurgical.
Postvagotomy.
Radiation therapy.
Short gut syndrome.
Small bowel resection.
Strictures.
Toxic megacolon.
Tropical sprue.
Volvulus.
Whipple disease.

Endocrine Related

Carcinoid syndrome (serotonin).
Hormonal hypersecretion.
Hyperthyroidism (thyroid hormone).
Medullary carcinoma of the thyroid (calcitonin).
Pancreatic cholera (VIP).
Somatostatinoma (somatostatin).
Systemic mastocytosis (histamine).
Zollinger-Ellison syndrome (gastrin).

Endocrine pathology

Adrenal insufficiency.
Diabetes enteropathy.
Hypoparathyroidism.
Pancreatic insufficiency.

Systemic Illness/Other

Alcoholism.
Amyloidosis.
Connective tissue disease.
Cystic fibrosis.
Ectopic pregnancy.
Hemolytic-uremic syndrome.
Henoch-Schönlein purpura.
Lymphoma.
Otitis media—infants.
Pelvic inflammatory disease.
Pneumonia/sepsis.
Pyelonephritis.
Scleroderma/SLE.
Severe malnutrition.
Stevens-Johnson syndrome.
Toxic shock syndrome.
Wilson disease.

Miscellaneous:
Factitious diarrhea.
Runner's diarrhea.

ACE, Angiotensin-converting enzyme; *GI,* gastrointestinal; *NSAIDs,* nonsteroidal antiinflammatory drugs; *SLE,* systemic lupus erythematosus; *VIP,* vasoactive intestinal polypeptide.

DIARRHEA IN PATIENTS WITH AIDS[26]

ICD-10CM # R19.7 Diarrhea, unspecified

PROTOZOA

*Microsporidium.**
Cryptosporidium spp.*
Isospora belli.
Toxoplasma spp.
Giardia lamblia.
Entamoeba histolytica.
Leishmania donovani.
Blastocystis hominis.
Cyclospora spp.
Pneumocystis jiroveci.

BACTERIA

Clostridium difficile.
Salmonella spp.
Shigella spp.
Campylobacter jejuni.
Mycobacterium avium complex.
Mycobacterium tuberculosis.
SIBO.
Vibrio spp.

VIRUSES

CMV.
HSV.
Adenoviruses.
Rotavirus spp.
Norovirus.
HIV?

FUNGI

Histoplasmosis.
Coccidioidomycosis.
Cryptococcosis.
Candidiasis.
Penicillium marneffei.

NEOPLASMS

Lymphoma.
Kaposi sarcoma.

IDIOPATHIC

"AIDS enteropathy."

DRUG INDUCED

HIV protease inhibitors.

PANCREATIC DISEASE

Pancreatic insufficiency.
Chronic pancreatitis.
Infectious pancreatitis (CMV, MAC).
Drug-induced pancreatitis (e.g., pentamidine).

CMV, cytomegalovirus.

*More frequent cause.

DIARRHEA, PEDIATRIC PATIENT[54]

ICD-10CM # R19.7 Diarrhea, unspecified

INFANT

Acute

Common:
Gastroenteritis (viral > bacterial > protozoal).
Systemic infection.
Antibiotic associated.
Overfeeding.

Rare:
Primary disaccharidase deficiency.
Hirschsprung toxic colitis.
Adrenogenital syndrome.
Neonatal opiate withdrawal.

Chronic

Common:
Postinfectious secondary lactase deficiency.
Cow's milk or soy protein intolerance (allergy).
Chronic nonspecific diarrhea of infancy.
Excessive fruit juice (sorbitol) ingestion.
Celiac disease.
Cystic fibrosis.
AIDS enteropathy.

Rare:
Primary immune defects.
Autoimmune enteropathy.
IPEX and IPEX-like syndromes.
Glucose-galactose malabsorption.
Microvillus inclusion disease (microvillus atrophy).
Congenital transport defects (chloride, sodium).
Primary bile acid malabsorption.
Factitious syndrome by proxy.
Hirschsprung disease.
Shwachman syndrome.
Secretory tumors.
Acrodermatitis enteropathica.
Lymphangiectasia.
Abetalipoproteinemia.
Eosinophilic gastroenteritis.
Short bowel syndrome.

CHILD

Acute

Common:
Gastroenteritis (viral > bacterial > protozoal).
Food poisoning.
Systemic infection.
Antibiotic associated.

Rare:
Toxic ingestion.
Hemolytic uremic syndrome.
Intussusception.

Chronic

Common:
Postinfectious secondary. lactase deficiency.
Irritable bowel syndrome.
Celiac disease.
Cystic fibrosis.
Lactose intolerance.
Excessive fruit juice (sorbitol) ingestion.
Giardiasis.

Inflammatory bowel disease.
AIDS enteropathy.
Rare:
Primary and acquired immune defects.
Secretory tumors.
Pseudoobstruction.
Sucrase-isomaltase deficiency.
Eosinophilic gastroenteritis.
Secretory tumors.

ADOLESCENT

Acute
Common:
Gastroenteritis (viral > bacterial > protozoal).
Food poisoning.
Antibiotic associated.
Rare:
Hyperthyroidism.
Appendicitis.
Chronic
Common:
Irritable bowel syndrome.
Inflammatory bowel disease.
Lactose intolerance.
Giardiasis.
Laxative abuse (anorexia nervosa).
Constipation with encopresis.
Rare:
Secretory tumor.
Primary bowel tumor.
Parasitic infections and venereal diseases.
Appendiceal abscess.
Addison disease.

IPEX, Immunodysregulation polyendocrinopathy enteropathy X-linked.

DIARRHEA, TUBE-FED PATIENT[32]

ICD-10CM # K91.89 Other postprocedural complications and disorders of digestive system

COMMON CAUSES UNRELATED TO TUBE FEEDING

Elixir medications containing sorbitol.
Magnesium-containing antacids.
Antibiotic-induced sterile gut.
Pseudomembranous colitis.

POSSIBLE CAUSES RELATED TO TUBE FEEDING

Inadequate fiber to form stool bulk.
High fat content of formula (in the presence of fat malabsorption syndrome).
Bacterial contamination of enteral products and delivery systems (causal association with diarrhea not documented).
Rapid advancement in rate (after the GI tract is unused for prolonged periods).

UNLIKELY CAUSES RELATED TO TUBE FEEDING

Formula hyperosmolality (proven not to be the cause of diarrhea).
Lactose (absent from nearly all enteral feeding formulas).

DIFFUSE PARENCHYMAL LUNG DISEASE, DRUG-INDUCED[92]

ICD-10CM # J84.89 Other specified interstitial pulmonary diseases

CYTOTOXIC CHEMOTHERAPY

Bleomycin.
Busulfan.
Cyclophosphamide.
Gemcitabine.
Nitrosoureas.
Taxanes (e.g., paclitaxel, docetaxel).

ANTIMETABOLITES

Methotrexate.

TARGETED BIOLOGIC AGENTS

Tumor necrosis factor (TNF)-α inhibitors or soluble receptors:
- Infliximab.
- Adalimumab.
- Certolizumab pegol.
- Etanercept.

Tyrosine kinase inhibitors:
- Afatinib.
- Erlotinib.
- Gefitinib.
- Idelalisib.
- Imatinib.
- Osimertinib.
- Trametinib.

Checkpoint inhibitors (antibodies against PD-1, PD-1 ligand, or CTLA-4):
- Ipilimumab.
- Nivolumab.
- Pembrolizumab.

Inhibitors of anaplastic lymphoma kinase (ALK):
- Alectinib.
- Ceritinib.
- Crizotinib.

MISCELLANEOUS

Trastuzumab (monoclonal antibody against HER2).
Rituximab (monoclonal antibody against CD20).
Inhibitors of mechanistic target of rapamycin (mTOR, e.g., everolimus).

MISCELLANEOUS OTHER DRUGS

Nitrofurantoin.
Amiodarone.

DRUG-INDUCED SYNDROMES

Drug-induced lupus (e.g., procainamide, hydralazine).
Drug-induced pulmonary infiltrates with eosinophilia (e.g., sulfa-containing drugs).

DIPLOPIA, BINOCULAR

ICD-10CM # H53.2 Diplopia

Cranial nerve palsy (3rd, 4th, 6th).
Thyroid eye disease.
Myasthenia gravis.
Decompensated strabismus.
Orbital trauma with blowout fracture.
Orbital pseudotumor.
Cavernous sinus thrombosis.

DIPLOPIA, MONOCULAR

ICD-10CM # H53.2 Diplopia

Postoperative corrected long-standing tropia.
Defective contact lenses.
Poorly fitting bifocals.
Trauma to iris.
Corneal disorder (e.g., dry eye, astigmatism).
Cataracts.
Lens subluxation.
Nystagmus.
Eyelid twitching.
Foreign body in aqueous or vitreous media.
Migraine.
Lesions of occipital cortex.
Psychogenic.

DIPLOPIA, VERTICAL

ICD-10CM # H53.2 Diplopia

Myasthenia.
Superior oblique palsy.
Myositis or pseudotumor with orbital involvement.
Lymphoma or metastases affecting the orbits.
Brain stem or cerebellar lesions.
Hydrocephalus.
Third nerve palsy.
Botulism.
Wernicke encephalopathy.
Dysthyroid orbitopathy (muscle infiltration).

DIZZINESS

ICD-10CM # R42 Dizziness and giddiness

Viral syndrome.
Anxiety, hyperventilation.
Benign positional paroxysmal vertigo.
Medications (e.g., sedatives, antihypertensives, analgesics).
Withdrawal from medications (e.g., benzodiazepines, SSRIs).
Alcohol or drug abuse.
Postural hypotension.
Hypoglycemia, hyperglycemia.
Hematologic disorders (e.g., anemia, polycythemia, leukemia).
Head trauma.
Menière disease.
Vertebrobasilar ischemia.
Cervical osteoarthritis.
Cardiac abnormalities (arrhythmias, cardiomyopathy, CHF, pericarditis).
Multiple sclerosis.
Peripheral vestibulopathy.
Air or sea travel.
Electrolyte abnormalities.
Eye problems (cornea, lens, retina).
Migraine.
Brain stem infarct.
Autonomic neuropathy.
Chronic otomastoiditis.
Complex partial seizures.
Ramsey Hunt syndrome.
Arteritis.
Syncope and presyncope.
Perilymph fistula.
Cerebellopontine tumor.
Hepatic or renal disease.

DRUG-INDUCED LUPUS[42]

ICD-10CM # M32.0 Drug-induced lupus

DRUGS IMPLEMENTED IN DRUG-INDUCED LUPUS

DRUGS WITH GOOD EVIDENCE OF ASSOCIATION

Adalimumab.
Carbamazepine.
Chlorpromazine.
Etanercept.
Ethosuximide.
Hydralazine.
Infliximab.
Isoniazid.
Methyldopa.
Minocycline.
Penicillamine.
Phenytoin.
Procainamide.
Quinidine.
Sulfasalazine.

CASE REPORTS

5-aminosalicylic acid.
Acebutolol.
Aminoglutethimide.
Amiodarone.
Amoproxan.
Anthiomaline.
Atenolol.
Atorvastatin.
Benoxaprofen.
Canavanine (L-).
Captopril.
Chlorprothixene.
Cimetidine.
Cinnarizine.
Clonidine.
Clozapine.
COL-3.
Danazol.
Diclofenac.
1,2-Dimethyl-3-hydroxypyride-4-1 (L1).
Disopyramide.
Esomeprazole.
Estrogens.
Etanercept.
Flutamide.
Fluvastatin.
Gold salts.
Griseofulvin.
Guanoxan.
Hydrazine.
Ibuprofen.
Infliximab.
Interferon (α,β).
Interleukin 2.
Labetalol.
Lamotrigine.
Lansoprazole.
Leuprolide acetate.
Levo-Dopa.
Levomeprazone.
Lithium carbonate.
Lovastatin.
Mephenytoin.
Mesalazine.
Methimazole.
Methylsergide.
Methylthiouracil.
Metrizamide.
Minoxidil.
Nalidixic acid.
Nitrofurantoin.
Nomifensine.
Oral contraceptives.
Olsalazine.
Omeprazole.
Oxyphenisatin.
Pantoprazole.
Para-aminosalicylic acid.
Penicillin.
Perazine.
Perphenazine.
Phenelzine.
Phenopyrazone.
Phenylbutazone.
Phenylethyacetylurea.
Practolol.
Prazosin.
Primidone.
Prinolol.
Promethazine.
Propylthiouracil.
Psoralen.
Pyrathiazine.
Pyrithioxine.
Quinine.
Rifamycin.
Sulfasalazine.
Simvastatin.
Spironolactone.
Streptomycin.
Sulindac.
Sulfadimethoxine.
Sulfamethoxypyridazine.
Terbinafine.
Tetracycline.
Tetrazine.
Thionamide.
Thioridazide.
Timolol eye drops.
Tolazamide.
Tolmetin.
Trimethadione.
Zafirlukast.

DRY EYE

ICD-10CM # H04.129 Dry eye syndrome of unspecified lacrimal gland

Contacts.
Medications (antihistamines, clonidine, beta-blockers, ibuprofen, scopolamine).
Keratoconjunctivitis sicca.
Trauma.
Environmental causes (air conditioning in patient with contacts).

DYSENTERY AND INFLAMMATORY ENTEROCOLITIS[10]

ICD-10CM # Varies with specific diagnosis

DIFFERENTIAL DIAGNOSIS OF ACUTE BACTERIAL DYSENTERY AND INFLAMMATORY ENTEROCOLITIS

Specific Infectious Processes

Bacillary dysentery (*Shigella dysenteriae, Shigella flexneri, Shigella sonnei, Shigella boydii;* invasive *Escherichia coli*).
Campylobacteriosis (*Campylobacter jejuni*).
Amebic dysentery (*Entamoeba histolytica*).
Ciliary dysentery (*Balantidium coli*).
Vibriosis (*Vibrio parahaemolyticus*).
Salmonellosis (*Salmonella typhimurium*).
Typhoid fever (*Salmonella typhi*).
Enteric fever (*Salmonella choleraesuis, Salmonella paratyphi*).
Yersiniosis (*Yersinia enterocolitica*).

Proctitis

Gonococcal (*Neisseria gonorrhoeae*).
Herpetic (herpes simplex virus).
Chlamydial (*Chlamydia trachomatis*).
Syphilitic (*Treponema pallidum*).

Other Syndromes

Necrotizing enterocolitis of the newborn.
Enteritis necroticans.
Pseudomembranous enterocolitis or *Clostridium difficile* colitis without overt pseudomembranes (*C. difficile*).
Diverticulitis.
Typhlitis.

Chronic Inflammatory Processes

Enteropathogenic and enteroaggregative *E. coli.*
Syphilis.
GI tuberculosis.
GI mycosis (including *Basidiobolus ranarum*).
Parasitic enteritis.

Syndromes without Known Infectious Cause

Idiopathic ulcerative colitis.
Crohn disease.
Radiation enteritis.
Ischemic colitis.
Allergic enteritis.
Brainerd diarrhea.

DYSLIPOPROTEINEMIAS, SECONDARY CAUSES[95]

ICD-10CM # E78.4 Other hyperlipidemia

Cause	Disorder
Metabolic	Diabetes.
	Lipodystrophy.
	Glycogen storage disorders.
Renal	Chronic renal failure.
	Glomerulonephritis with nephritic syndrome.
Hepatic	Cirrhosis.
	Biliary obstruction.
	Porphyria.
	Primary biliary cirrhosis (with secondary LCAT deficiency).
Hormonal	Estrogens.
	Progesterones.
	Growth hormone.
	Thyroid disorders (hypothyroidism).
	Corticosteroids.

Cause	Disorder
Lifestyle	Physical inactivity. Obesity. Diet rich in fats, saturated fats. Alcohol intake. Smoking.
Medications	Retinoic acid derivatives. Glucocorticoids. Exogenous estrogens. Thiazide diuretics. Beta-adrenergic blockers (selective). Testosterone and other anabolizing steroids. Immunosuppressive medications (cyclosporine). Antiviral medications (HIV protease inhibitors). Antischizophrenic medications.

HIV, Human immunodeficiency virus; *LCAT,* lecithin-cholesterol acyltransferase.

DYSPAREUNIA[24]

ICD-10CM # N94.1 Dyspareunia
N44.8 Other noninflammatory disorders of the testis
N50.8 Other specified disorders of male genital organs
N53.12 Painful ejaculation
F52.6 Dyspareunia not due to a substance or known physiological condition

INTROITAL

Vaginismus.
Intact or rigid hymen.
Clitoral problems.
Vulvovaginitis.
Vaginal atrophy: hypoestrogen.
Vulvar dystrophy.
Bartholin or Skene gland infection.
Inadequate lubrication.
Operative scarring.

MIDVAGINAL

Urethritis.
Trigonitis.
Cystitis.
Short vagina.
Operative scarring.
Inadequate lubrication.

DEEP

Endometriosis.
Pelvic infection.
Uterine retroversion.
Ovarian pathology.
GI.
Orthopedic.
Abnormal penile size or shape.

DYSPEPSIA AND PYROSIS, DIFFERENTIAL DIAGNOSIS DURING PREGNANCY[30]

ICD-10CM # K30 Dyspepsia, atonic
F45.3 Dyspepsia, psychogenic

DIFFERENTIAL DIAGNOSIS OF DYSPEPSIA OR PYROSIS DURING PREGNANCY

Gastroesophageal reflux disease.
Peptic ulcer disease.
Nausea and vomiting of pregnancy.
Hyperemesis gravidarum.
Pancreatitis.
Biliary colic.
Acute cholecystitis.
Viral hepatitis.
Appendicitis.
Acute fatty liver of pregnancy (in late pregnancy).
Irritable bowel syndrome/nonulcer dyspepsia.

DYSPHAGIA

ICD-10CM # R13.10 Dysphagia, unspecified

Esophageal obstruction: neoplasm, foreign body, achalasia, stricture, spasm, esophageal web, diverticulum, Schatzki ring.
Peptic esophagitis with stricture, Barrett stricture.
External esophageal compression: neoplasms (thyroid neoplasm, lymphoma, mediastinal tumors), thyroid enlargement, aortic aneurysm, vertebral spurs, aberrant right subclavian artery (dysphagia lusoria).
Hiatal hernia, GERD.
Oropharyngeal lesions: pharyngitis, glossitis, stomatitis, neoplasms.
Hysteria: globus hystericus.
Neurologic and/or neuromuscular disturbances: bulbar paralysis, myasthenia gravis, ALS, multiple sclerosis, Parkinsonism, CVA, diabetic neuropathy.
Toxins: poisoning, botulism, tetanus, postdiphtheritic dysphagia.
Systemic diseases: scleroderma, amyloidosis, dermatomyositis.
Candida and herpes esophagitis.
Presbyesophagus.

DYSPHAGIA, ESOPHAGEAL[26]

ICD-10CM # R13-14 Dysphagia, pharyngoesophageal phase

COMMON CAUSES OF ESOPHAGEAL DYSPHAGIA

Motility (Neuromuscular) Disorders
Primary
Achalasia.
Distal esophageal spasm.
Hypercontractile (jackhammer) esophagus.
Hypertensive LES.
Nutcracker (high-pressure) esophagus.
Other peristaltic abnormalities.[17]
Secondary
Chagas disease.
Reflux-related dysmotility.
Scleroderma and other rheumatologic disorders.
Structural (Mechanical) Disorders
Intrinsic
Carcinoma and benign tumors.
Diverticula.
Eosinophilic esophagitis.
Esophageal rings and webs (other than Schatzki ring).
Foreign body.
Lower esophageal (Schatzki) ring.
Medication-induced stricture.
Peptic stricture.
Extrinsic
Mediastinal mass.
Spinal osteophytes.
Vascular compression.

LES, lower esophageal sphincter.
[17] Peristaltic abnormalities include absent peristalsis and weak peristalsis, as well as hypertensive peristalsis (nutcracker esophagus).

DYSPHAGIA, OROPHARYNGEAL[86]

ICD-10CM # R13.12 Dysphagia, oropharyngeal phase

FUNCTIONAL DISORDERS

Central Nervous System
Stroke.
Head injury.
Parkinson disease.
Motor neuron disease.
Multiple sclerosis.
Tumor.
Drugs (e.g., phenothiazines).
Malformations (e.g., syrinx, Arnold–Chiari).
Neural
Motor neuron disease.
Myasthenia gravis.
Radiotherapy.
Poliomyelitis.
Familial dysautonomia.
Muscle
Autoimmune myopathy (polymyositis, dermatomyositis, systemic lupus erythematosus).
Thyrotoxic myopathy.
Guillain-Barré motor neuropathy.
Muscular dystrophies.

STRUCTURAL DISORDERS

Head/neck surgery.
Stricture.
Radiotherapy.
Tumor.
Pharyngeal pouch.
Web.
Extrinsic (e.g., osteophytes).

MISCELLANEOUS

Xerostomia.

DYSPNEA

ICD-10CM # R06.9 Unspecified abnormalities of breathing

Upper airway obstruction: trauma, neoplasm, epiglottitis, laryngeal edema, tongue retraction, laryngospasm, abductor paralysis of vocal cords, aspiration of foreign body.
Lower airway obstruction: neoplasm, COPD, asthma, aspiration of foreign body.

Pulmonary infection: pneumonia, abscess, empyema, TB, bronchiectasis.
Pulmonary hypertension.
Pulmonary embolism/infarction.
Parenchymal lung disease.
Pulmonary vascular congestion.
Cardiac disease: ASHD, valvular lesions, cardiac dysrhythmias, cardiomyopathy, pericardial effusion, cardiac shunts.
Space-occupying lesions: neoplasm, large hiatal hernia, pleural effusions.
Disease of chest wall: severe kyphoscoliosis, fractured ribs, sternal compression, morbid obesity.
Neurologic dysfunction: Guillain-Barré syndrome, botulism, polio, spinal cord injury.
Interstitial pulmonary disease: sarcoidosis, collagen vascular diseases, DIP, Hamman-Rich pneumonitis, etc.
Pneumoconioses: silicosis, berylliosis, etc.
Mesothelioma.
Pneumothorax, hemothorax, pleural effusion.
Inhalation of toxins.
Cholinergic drug intoxication.
Carcinoid syndrome.
Hematologic: anemia, polycythemia, hemoglobinopathies.
Thyrotoxicosis, myxedema.
Diaphragmatic compression caused by abdominal distention, subphrenic abscess, ascites.
Lung resection.
Metabolic abnormalities: uremia, hepatic coma, DKA.
Sepsis.
Atelectasis.
Psychoneurosis.
Diaphragmatic paralysis.
Pregnancy.

DYSTONIA, PEDIATRIC PATIENT[84]

ICD-10CM #	G24.9	Dystonia, unspecified
	G24.2	Idiopathic nonfamilial dystonia
	G24.1	Genetic torsion dystonia

CAUSES OF DYSTONIA IN CHILDHOOD

Static Injury/Structural Disorders
Cerebral palsy.
Hypoxic-ischemic injury.
Kernicterus.
Head trauma.
Encephalitis.
Tumors.
Stroke in the basal ganglia (which may be due to vascular abnormalities or varicella).
Congenital malformations affecting basal ganglia.
Hereditary/Degenerative Disorders
DYT1 (autosomal dominant, Torsin A).
DYT2 (autosomal-recessive, Hippocalcin).
DYT4 (autosomal dominant, β-tubulin 4a).
DYT5 (autosomal dominant, GTP cyclohydrolase 1).
DYT6 (autosomal dominant, THAP1).
DYT8 (autosomal dominant, Myofibrillogenesis regulator 1).
DYT9 (autosomal dominant, GLUT1).
DYT10 (autosomal dominant, PRRT2).
DYT11 (autosomal dominant [maternal imprinting], ε-Sarcoglycan).
DYT12 (autosomal dominant, Na^+/K^+ATPase α3 subunit).
DYT15 (autosomal dominant, unknown).
DYT16 (autosomal recessive, Protein kinase activator PRKRA).
Pantothenate kinase-associated neurodegeneration (PKAN; neuronal brain iron accumulation type 1, due to mutations in *PANK2*).
PLA2G6-associated neurodegeneration (PLAN).
Huntington disease (Westphal variant, IT15–4p16.3).
Spinocerebellar ataxias (SCAs, particularly SCA3/Machado-Joseph disease).
Striatal necrosis.
Leigh syndrome.
Neuroacanthocytosis.
HARP syndrome (hypoprebetalipoproteinemia, acanthocytosis, retinitis pigmentosa, and pallidal degeneration).
Tay-Sachs disease.
Sandhoff disease.
Niemann-Pick type C.
Metabolic Disease
Glutaric aciduria types 1 and 2.
Acyl-CoA dehydrogenase deficiencies.
Neurotransmitter disorders.
Mitochondrial disorders.
GM_1 gangliosidosis.
Lesch-Nyhan disease.
Wilson disease.
Vitamin E deficiency.
Methylmalonic aciduria.
Tyrosinemia.
Drugs/Toxins
Neuroleptic and neuroleptic-like antiemetic medications (haloperidol, chlorpromazine, olanzapine, risperidone, prochlorperazine).
Calcium channel blockers.
Stimulants (amphetamine, cocaine, ergot alkaloids).
Anticonvulsants (carbamazepine, phenytoin).
Thallium.
Manganese.
Carbon monoxide.
Ethylene glycol.
Cyanide.
Methanol.
Paroxysmal Disorders
Paroxysmal kinesigenic dyskinesia (PKD).
Paroxysmal nonkinesigenic dyskinesia (PNKD).
Exercise-induced dyskinesia (PED).

DYSURIA

ICD-10CM #	R30.0	Dysuria
	R30.9	Painful micturition, unspecified

Urinary tract infection.
Estrogen deficiency (in postmenopausal female).
Vaginitis.
Genital infection (e.g., herpes, condyloma).
Interstitial cystitis.
Chemical irritation (e.g., deodorant aerosols, douches).
Meatal stenosis or stricture.
Reiter syndrome.
Bladder neoplasm.
GI etiology (diverticulitis, Crohn disease).
Impaired bladder or sphincter action.
Urethral carbuncle.
Chronic fibrosis posttrauma.
Radiation therapy.
Prostatitis.
Urethritis (gonococcal, *Chlamydia*).
Behçet syndrome.
Stevens-Johnson syndrome.

EARACHE[76]

ICD-10CM #	H92.09	Otalgia, unspecified ear

Otitis media.
Serous otitis media.
Eustachitis.
Otitis externa.
Otitic barotrauma.
Mastoiditis.
Foreign body.
Impacted cerumen.
Referred otalgia, as with TMJ dysfunction, dental problems, and tumors.

ECTOPIC ACTH SECRETION[32]

ICD-10CM #	E34.2	Ectopic hormone secretion, not elsewhere classified

Small cell carcinoma of lung.
Endocrine tumors of foregut origin.
Thymic carcinoid.
Islet cell tumor.
Medullary carcinoid, thyroid.
Bronchial carcinoid.
Pheochromocytoma.
Ovarian tumors.

EDEMA, CHILDREN[43]

ICD-10CM #	R60.0	Localized edema
	R60.1	Generalized edema
	R60.9	Edema, unspecified

CARDIOVASCULAR

Congestive heart failure.
Acute thrombi or emboli.
Vasculitis of many types.

RENAL

Nephrotic syndrome.
Glomerulonephritis of many types.
End-stage renal failure.

ENDOCRINE OR METABOLIC

Thyroid disease.
Starvation.
Hereditary angioedema.

IATROGENIC

Drugs (diuretics and steroids).
Water or salt overload.

Pulmonary infection: pneumonia, abscess, empyema, TB, bronchiectasis.
Pulmonary hypertension.
Pulmonary embolism/infarction.
Parenchymal lung disease.
Pulmonary vascular congestion.
Cardiac disease: ASHD, valvular lesions, cardiac dysrhythmias, cardiomyopathy, pericardial effusion, cardiac shunts.
Space-occupying lesions: neoplasm, large hiatal hernia, pleural effusions.
Disease of chest wall: severe kyphoscoliosis, fractured ribs, sternal compression, morbid obesity.
Neurologic dysfunction: Guillain-Barré syndrome, botulism, polio, spinal cord injury.
Interstitial pulmonary disease: sarcoidosis, collagen vascular diseases, DIP, Hamman-Rich pneumonitis, etc.
Pneumoconioses: silicosis, berylliosis, etc.
Mesothelioma.
Pneumothorax, hemothorax, pleural effusion.
Inhalation of toxins.
Cholinergic drug intoxication.
Carcinoid syndrome.
Hematologic: anemia, polycythemia, hemoglobinopathies.
Thyrotoxicosis, myxedema.
Diaphragmatic compression caused by abdominal distention, subphrenic abscess, ascites.
Lung resection.
Metabolic abnormalities: uremia, hepatic coma, DKA.
Sepsis.
Atelectasis.
Psychoneurosis.
Diaphragmatic paralysis.
Pregnancy.

DYSTONIA, PEDIATRIC PATIENT[84]

ICD-10CM #	G24.9	Dystonia, unspecified
	G24.2	Idiopathic nonfamilial dystonia
	G24.1	Genetic torsion dystonia

CAUSES OF DYSTONIA IN CHILDHOOD

Static Injury/Structural Disorders
Cerebral palsy.
Hypoxic-ischemic injury.
Kernicterus.
Head trauma.
Encephalitis.
Tumors.
Stroke in the basal ganglia (which may be due to vascular abnormalities or varicella).
Congenital malformations affecting basal ganglia.
Hereditary/Degenerative Disorders
DYT1 (autosomal dominant, Torsin A).
DYT2 (autosomal-recessive, Hippocalcin).
DYT4 (autosomal dominant, β-tubulin 4a).
DYT5 (autosomal dominant, GTP cyclohydrolase 1).
DYT6 (autosomal dominant, THAP1).
DYT8 (autosomal dominant, Myofibrillogenesis regulator 1).
DYT9 (autosomal dominant, GLUT1).
DYT10 (autosomal dominant, PRRT2).
DYT11 (autosomal dominant [maternal imprinting], ε-Sarcoglycan).
DYT12 (autosomal dominant, Na^+/K^+ATPase α3 subunit).
DYT15 (autosomal dominant, unknown).
DYT16 (autosomal recessive, Protein kinase activator PRKRA).
Pantothenate kinase-associated neurodegeneration (PKAN; neuronal brain iron accumulation type 1, due to mutations in *PANK2*).
PLA2G6-associated neurodegeneration (PLAN).
Huntington disease (Westphal variant, IT15–4p16.3).
Spinocerebellar ataxias (SCAs, particularly SCA3/Machado-Joseph disease).
Striatal necrosis.
Leigh syndrome.
Neuroacanthocytosis.
HARP syndrome (hypoprebetalipoproteinemia, acanthocytosis, retinitis pigmentosa, and pallidal degeneration).
Tay-Sachs disease.
Sandhoff disease.
Niemann-Pick type C.
Metabolic Disease
Glutaric aciduria types 1 and 2.
Acyl-CoA dehydrogenase deficiencies.
Neurotransmitter disorders.
Mitochondrial disorders.
GM_1 gangliosidosis.
Lesch-Nyhan disease.
Wilson disease.
Vitamin E deficiency.
Methylmalonic aciduria.
Tyrosinemia.
Drugs/Toxins
Neuroleptic and neuroleptic-like antiemetic medications (haloperidol, chlorpromazine, olanzapine, risperidone, prochlorperazine).
Calcium channel blockers.
Stimulants (amphetamine, cocaine, ergot alkaloids).
Anticonvulsants (carbamazepine, phenytoin).
Thallium.
Manganese.
Carbon monoxide.
Ethylene glycol.
Cyanide.
Methanol.
Paroxysmal Disorders
Paroxysmal kinesigenic dyskinesia (PKD).
Paroxysmal nonkinesigenic dyskinesia (PNKD).
Exercise-induced dyskinesia (PED).

DYSURIA

ICD-10CM #	R30.0	Dysuria
	R30.9	Painful micturition, unspecified

Urinary tract infection.
Estrogen deficiency (in postmenopausal female).
Vaginitis.
Genital infection (e.g., herpes, condyloma).
Interstitial cystitis.
Chemical irritation (e.g., deodorant aerosols, douches).
Meatal stenosis or stricture.
Reiter syndrome.
Bladder neoplasm.
GI etiology (diverticulitis, Crohn disease).
Impaired bladder or sphincter action.
Urethral carbuncle.
Chronic fibrosis posttrauma.
Radiation therapy.
Prostatitis.
Urethritis (gonococcal, *Chlamydia*).
Behçet syndrome.
Stevens-Johnson syndrome.

EARACHE[76]

ICD-10CM #	H92.09	Otalgia, unspecified ear

Otitis media.
Serous otitis media.
Eustachitis.
Otitis externa.
Otitic barotrauma.
Mastoiditis.
Foreign body.
Impacted cerumen.
Referred otalgia, as with TMJ dysfunction, dental problems, and tumors.

ECTOPIC ACTH SECRETION[32]

ICD-10CM #	E34.2	Ectopic hormone secretion, not elsewhere classified

Small cell carcinoma of lung.
Endocrine tumors of foregut origin.
Thymic carcinoid.
Islet cell tumor.
Medullary carcinoid, thyroid.
Bronchial carcinoid.
Pheochromocytoma.
Ovarian tumors.

EDEMA, CHILDREN[43]

ICD-10CM #	R60.0	Localized edema
	R60.1	Generalized edema
	R60.9	Edema, unspecified

CARDIOVASCULAR

Congestive heart failure.
Acute thrombi or emboli.
Vasculitis of many types.

RENAL

Nephrotic syndrome.
Glomerulonephritis of many types.
End-stage renal failure.

ENDOCRINE OR METABOLIC

Thyroid disease.
Starvation.
Hereditary angioedema.

IATROGENIC

Drugs (diuretics and steroids).
Water or salt overload.

HEMATOLOGIC
Hemolytic disease of the newborn.

GASTROINTESTINAL
Hepatic cirrhosis.
Protein-losing enteritis.
Lymphangiectasis.
Cystic fibrosis.
Celiac disease.
Enteritis of many types.

LYMPHATIC ABNORMALITIES
Congenital (gonadal dysgenesis).
Acquired.

EDEMA, GENERALIZED

ICD-10CM #		
	R60.0	Localized edema
	R60.1	Generalized edema
	R60.9	Edema, unspecified

Congestive heart failure (CHF).
Cirrhosis.
Nephrotic syndrome.
Pregnancy.
Idiopathic.
Acute nephritic syndrome.
Myxedema.
Medications (NSAIDs, estrogens, vasodilators).

EDEMA, LEG, UNILATERAL[58]

ICD-10CM #		
	R60.0	Localized edema
	R60.9	Edema, unspecified

WITH PAIN
DVT.
Postphlebitic syndrome.
Popliteal cyst rupture.
Gastrocnemius rupture.
Cellulitis.
Psoas or other abscess.

WITHOUT PAIN
DVT.
Postphlebitic syndrome.
Other venous insufficiency (after saphenous vein harvest, varicosities).
Lymphatic obstruction/lymphedema (carcinoma, lymphoma, sarcoidosis, filariasis, retroperitoneal fibrosis).

EDEMA OF LOWER EXTREMITIES

ICD-10CM #		
	R60.0	Localized edema
	R60.9	Edema, unspecified

CHF (right-sided).
Hepatic cirrhosis.
Nephrosis.
Myxedema.
Lymphedema.
Pregnancy.
Abdominal mass: neoplasm, cyst.
Venous compression from abdominal aneurysm.
Varicose veins.
Bilateral cellulitis.
Bilateral thrombophlebitis.
Vena cava thrombosis, venous thrombosis.
Retroperitoneal fibrosis.

EJECTION SOUND OR CLICK

ICD-10CM #		
	R01.2	Other cardiac sounds

Aortic regurgitation.
Aortic root dilatation.
Systemic hypertension.
Chronic pulmonary hypertension.
Tetralogy of Fallot.
Atrial septal defect.
Pulmonary valve stenosis.
Aortic aneurysm.

ELBOW PAIN

ICD-10CM #		
	M25.529	Pain in unspecified elbow

Trauma.
Infection.
Inflammatory arthritis.
Lateral or medial epicondylitis.
Entrapment neuropathy.
Olecranon bursitis.
Osteoarthritis.
Gout.
Cervical disease (referred pain).
Shoulder disease (referred pain).
Partial subluxation.
Synovial osteochondromatosis.
Loose body.

ELEVATED HEMIDIAPHRAGM

ICD-10CM #		
	J98.6	Disorders of diaphragm
	Q79.0	Congenital diaphragmatic hernia
	Q79.1	Other congenital malformations of diaphragm

Neoplasm (bronchogenic carcinoma, mediastinal neoplasm, intrahepatic lesion).
Substernal thyroid.
Infectious process (pneumonia, empyema, TB, subphrenic abscess, hepatic abscess).
Atelectasis.
Idiopathic.
Eventration.
Phrenic nerve dysfunction (myelitis, myotonia, herpes zoster).
Trauma to phrenic nerve or diaphragm (e.g., surgery).
Aortic aneurysm.
Intraabdominal mass.
Pulmonary infarction.
Pleurisy.
Radiation therapy.
Rib fracture.

EMBOLI, ARTERIAL[58]

ICD-10CM #		
	I74.3	Embolism and thrombosis of arteries of the lower extremities
	I74.2	Embolism and thrombosis of arteries of the upper extremities

Myocardial infarction with mural thrombi.
Atrial fibrillation.
Cardiomyopathies.
Prosthetic heart valves.
CHF.
Endocarditis.
Left ventricular aneurysm.
Left atrial myxoma.
Sick sinus syndrome.
Paradoxical embolus from venous thrombosis.
Aneurysms of large blood vessels.
Atheromatous ulcers of large blood vessels.

EMESIS, PEDIATRIC AGE[43]

ICD-10CM #		
	R11.10	Vomiting, unspecified
	R11.11	Vomiting without nausea
	R11.12	Projectile vomiting

INFANCY
Gastrointestinal Tract
Congenital
Regurgitation: chalasia, gastroesophageal reflux.
Atresia: stenosis (tracheoesophageal fistula, prepyloric diaphragm, intestinal atresia).
Duplication.
Volvulus (errors in rotation and fixation, Meckel diverticulum).
Congenital bands.
Hirschsprung disease.
Meconium ileus (cystic fibrosis), meconium plug.
Acquired
Acute infectious gastroenteritis, food poisoning (staphylococcal, clostridial).
Pyloric stenosis.
Gastritis, duodenitis.
Intussusception.
Incarcerated hernia—inguinal, internal secondary to old adhesions.
Cow's milk protein intolerance, food allergy, eosinophilic gastroenteritis.
Disaccharidase deficiency.
Celiac disease—presents after introduction of gluten in diet; inherited risk.
Adynamic ileus—the mediator for many nongastrointestinal causes.
Neonatal necrotizing enterocolitis.
Chronic granulomatous disease with gastric outlet obstruction.
Nongastrointestinal Tract
Infectious: otitis, urinary tract infection, pneumonia, upper respiratory tract infection, sepsis, meningitis.
Metabolic: aminoaciduria and organic aciduria, galactosemia, fructosemia, adrenogenital syndrome, renal tubular acidosis, diabetic ketoacidosis, Reye syndrome.
CNS: trauma, tumor, infection, diencephalic syndrome, rumination, autonomic responses (pain, shock).
Medications: anticholinergics, aspirin, alcohol, idiosyncratic reaction (e.g., codeine).

CHILDHOOD
Gastrointestinal Tract
Peptic ulcer—vomiting is a common presentation in children younger than 6 yr old.

Trauma: duodenal hematoma, traumatic pancreatitis, perforated bowel.
Pancreatitis: mumps, trauma, cystic fibrosis, hyperparathyroidism, hyperlipidemia, organic acidemias.
Crohn disease.
Idiopathic intestinal pseudoobstruction.
Superior mesenteric artery syndrome.
Nongastrointestinal Tract
CNS: cyclic vomiting, migraine, anorexia nervosa, bulimia.

ENCEPHALOMYELITIS, NONVIRAL CAUSES[58]

ICD-10CM #		
	G04.81	Other encephalitis and encephalomyelitis

Subacute bacterial endocarditis.
Rocky Mountain spotted fever.
Typhus.
Ehrlichia.
Q fever.
Chlamydia.
Mycoplasma.
Legionella.
Brucellosis.
Listeria.
Whipple disease.
Cat-scratch disease.
Syphilis (meningovascular).
Relapsing fever.
Lyme disease.
Leptospirosis.
Nocardia.
Actinomycosis.
Tuberculosis.
Cryptococcus.
Histoplasma.
Toxoplasma.
Plasmodium falciparum.
Trypanosomiasis.
Behçet disease.
Vasculitis.
Carcinoma.
Drug reactions.

ENCEPHALOPATHY, HYPERTENSIVE[88]

ICD-10CM #	Varies with specific diagnosis

Cerebral infarction.
Subarachnoid hemorrhage.
Intracerebral hemorrhage.
Subdural or epidural hematoma.
Brain tumor or other mass lesion.
Seizure disorder.
CNS vasculitis.
Encephalitis/meningitis.
Drug ingestion.
Drug withdrawal.

ENCEPHALOPATHY, METABOLIC[82]

ICD-10CM #		
	F10.27	Alcohol dependence with alcohol-induced persisting dementia
	K72.90	Hepatic failure, unspecified without coma
	K72.91	Hepatic failure, unspecified with coma
	G92	Toxic encephalopathy
	T56.0X1A	Toxic effect of lead and its compounds, accidental (unintentional), initial encounter
	T56.0X2A	Toxic effect of lead and its compounds, intentional self-harm, initial encounter

Substrate deficiency: hypoxia/ischemia, carbon monoxide poisoning, hypoglycemia.
Cofactor deficiency: thiamine, vitamin B_{12}, pyridoxine (INH administration).
Electrolyte disorders: hyponatremia, hypercalcemia, carbon dioxide narcosis, dialysis, hypermagnesemia, disequilibrium syndrome.
Endocrinopathies: DKA, hyperosmolar coma, hypothyroidism, hyperadrenocorticism, hyperparathyroidism.
Endogenous toxins: liver disease, uremia, porphyria.
Exogenous toxins: drug overdose (sedative/hypnotics, ethanol, narcotics, salicylates, tricyclic antidepressants), drug withdrawal, toxicity of therapeutic medications, industrial toxins (e.g., organophosphates, heavy metals), sepsis.
Heat stroke.
Epilepsy (postictal).

ENDOMETRIAL THICKENING[74]

ICD-10CM #	Varies with specific diagnosis

CAUSES OF ENDOMETRIAL THICKENING

Early intrauterine pregnancy.
Incomplete abortion.
Ectopic pregnancy.
Retained products of conception.
Trophoblastic disease.
Endometritis.
Adhesions.
Hyperplasia.
Polyps.
Carcinoma.

ENTERIC FEVER[19]

ICD-10CM #		
	A01.00	Typhoid fever, unspecified
	A01.3	Paratyphoid fever
	R50.9	Fever, unspecified

Epstein-Barr infection.
Dengue.
Tuberculosis.
Brucellosis.
Bartonella henselae.
Leptospirosis.
Tularemia.
Ehrlichiosis.
Plague.
Typhus.
Malaria.
Disseminated histoplasmosis.

ENTHESOPATHY

ICD-10CM #		
	M46.00	Spinal enthesopathy, site unspecified

Viremia or bacteremia.
Ankylosing spondylitis.
Psoriatic arthritis.
Drug-induced (quinolones, etretinate).
Reactive arthritis.
DISH.
Reiter syndrome.

EOSINOPHILIA, DISEASE ASSOCIATIONS[57]

ICD-10CM #		
	D72.1	Eosinophilia
	NEC J82	Eosinophilia, pulmonary

DISEASES, SYNDROMES, AND CONDITIONS COMMONLY ASSOCIATED WITH PERIPHERAL BLOOD EOSINOPHILIA AND/OR TISSUE EOSINOPHILIA

Infectious Agents
Parasitic Infections
Tropical eosinophilia.
Visceral larval migrans (VLM, toxocariasis).
Helminth infections.
Filariasis (*Wuchereria bancrofti, Brugia malayi*).
Onchocerciasis.
Schistosomiasis.
Fascioliasis.
Paragonimiasis.
Strongyloidiasis.
Trichinosis.
Hookworm.
Ascariasis.
Echinococcosis/hydatid disease.
Fungal Infections
Coccidioidomycosis.
Cryptococcosis (CSF eosinophilia) in HIV.
Allergic Diseases
Asthma (atopic and intrinsic, nasal polyps, aspirin intolerance syndromes).
Bronchopulmonary aspergillosis.
Allergic rhinitis.
Urticarias (acute allergic and chronic idiopathic).
Atopic dermatitis.
Acute drug (hypersensitivity) reactions (interstitial nephritis, cholestatic hepatitis, exfoliative dermatitis).
Respiratory Tract Disorders
Hypersensitivity pneumonitis (rare).
Allergic bronchopulmonary aspergillosis.
Eosinophilic pneumonia.
Transient pulmonary infiltrates (Löeffler syndrome).
Prolonged pulmonary infiltrates with eosinophilia (PIE syndrome).
Tropical pulmonary eosinophilia (TPE).
Bronchiectasis.
Cystic fibrosis.
Endocrinologic Disorders
Addison disease.

Gastrointestinal Diseases
Inflammatory bowel disease (IBD).
Eosinophilic gastroenteritis, eosinophilic esophagitis (EE).
Allergic gastroenteritis (young children).
Celiac disease (when associated with EE).
Toxic Reactions to Ingested Agents
Eosinophil myalgia syndrome (L-tryptophan).
Toxic oil syndrome.
Reactions to Cytokine Therapies
IL-2 and IL-2 plus lymphokine activated killer (LAK) cells.
GM-CSF therapy.
Cutaneous Disorders
Atopic dermatitis.
Immunologic skin diseases.
Scabies.
Myiasis.
Chlamydial pneumonia of infancy.
Scarlet fever and pneumococcal pneumonia (convalescent phase).
Cat scratch disease.
Eosinophilic cellulitis (Wells syndrome).
Episodic angioedema with eosinophilia.
Chronic idiopathic urticaria.
Bullous pemphigoid.
Herpes gestationis.
Angioblastic lymphoid hyperplasia (Kimura disease).
Immunodeficiency Syndromes
Wiskott-Aldrich syndrome.
Selective IgA deficiency with atopy.
Hyper-IgE recurrent infection syndrome (Job syndrome).
Swiss-type and sex-linked combined immunodeficiency.
Nezelof syndrome.
Graft-versus-host-disease (GVHD).
Connective Tissue Diseases
Vasculitis/Collagen Vascular Disorders
Hypersensitivity vasculitis.
Allergic granulomatosis with angiitis (Churg-Strauss syndrome).
Serum sickness.
Eosinophilic fasciitis.
Sjögren syndrome.
Rheumatoid arthritis (severe).
Neoplastic, Myeloproliferative, and Lymphoproliferative Neoplasms and Syndromes
Neoplastic
Ovarian carcinoma.
Solid tumors (mucin-secreting, epithelial cell origin).
Chronic eosinophil leukemia.
Idiopathic hypereosinophilic syndromes (HES).
Systemic mastocytosis.
Myeloproliferative
Chronic myelogenous leukemia (CML) acute myelogenous leukemia (AML) and myelodysplastic syndrome (MDS).
Myelomonocytic leukemia with bone marrow eosinophilia (M4Eo, inversion 16).
Lymphoproliferative
T-cell lymphocytic leukemia.
Lymphomas (T cell, Hodgkin disease).
Angioimmunoblastic lymphadenopathy.
Rare Causes
Chronic active hepatitis.
Chronic dialysis.
Acute pancreatitis.
Postirradiation.
Hypopituitarism.

EOSINOPHILIA, GI[26]

ICD-10CM # D72.1 Eosinophilia

CAUSES OF GI EOSINOPHILIA

GERD
Eosinophilic GI disorders:
Eosinophilic esophagitis:
Connective tissue disease-associated eosinophilic esophagitis.
Familial eosinophilic esophagitis.
Eosinophilic gastritis.
Eosinophilic enteritis.
Eosinophilic gastroenteritis.
Infections:
Schistosomiasis.
Anisakiasis.
GI basidiobolomycosis.
Toxocariasis.
Celiac disease.
Hypereosinophilic syndrome.
Drug hypersensitivity response.
IBD.
Transplant-associated eosinophilic enteritis.
Eosinophilic granulomatosis with polyangiitis.
Toxic injury.
Graft-versus-host disease.

EOSINOPHILIC LUNG DISEASE[36]

ICD-10CM # NEC J82 Eosinophilia, pulmonary

IDIOPATHIC

Simple pulmonary eosinophilia (Löffler syndrome).
Acute eosinophilic pneumonia.
Chronic eosinophilic pneumonia.
Hypereosinophilic syndrome.

DRUG-INDUCED

Aminosalicylic acid.
Para-aminosalicylic acid.
NSAIDs.
Captopril.
Cocaine.
Minocycline.
Nitrofurantoin.
Phenytoin.

INFECTION

Parasitic (ascariasis, paragonimiasis. tropical eosinophilia).
Fungal (aspergillus).
Bacterial (TB, atypical mycobacterial infection, brucella).
Viral (respiratory syncytial virus).

IMMUNOLOGIC DISEASES

Granulomatosis with polyangiitis.
Churg–Strauss syndrome.
Rheumatoid disease.
Sarcoidosis.

NEOPLASMS

Bronchogenic carcinoma.
Bronchial carcinoid.
Lymphoma (Hodgkin, non-Hodgkin).

EOSINOPHILIA, PARASITIC CAUSES[10]

ICD-10CM # Varies with specific diagnosis

PARASITIC CAUSES OF EOSINOPHILIA

Widespread Geographic Distribution
Ascariasis (migratory phase).
Hookworm.†
Strongyloidiasis.*‡
Tropical pulmonary eosinophilia.
Lymphatic filariasis.
Schistosomiasis.
Toxocariasis.
Cysticercosis (*Taenia solium*).
Echinococcosis (cyst rupture).
Trichinosis.
Trichuriasis.
Aberrant helminthiasis from animals.
Limited Geographic Distribution
Clonorchiasis.
Paragonimiasis.
Fascioliasis.
Angiostrongyliasis.
Opisthorchiasis.
Onchocerciasis, loiasis, and other nonlymphatic filariases.
Gnathostomiasis.
Capillariasis.
Trichostrongyliasis.

EPIGASTRIC PAIN[86]

ICD-10CM #	R10.816	Epigastric abdominal tenderness
	R10.826	Epigastric rebound abdominal tenderness

Peptic ulceration (uncomplicated).[18]
Peptic ulceration (perforated).
Biliary colic.
Acute pancreatitis.
Abdominal aortic aneurysm.
Anxiety.
Inferior wall MI.

EPILEPSY

ICD-10CM #	G40.909	Epilepsy, unspecified, not intractable, without status epilepticus

Psychogenic spells.

† Moderate to marked during larval migration in early infection; most often absent or very mild during chronic infection.
* Most frequent parasitic causes of massive eosinophilia (>5000/mm^3).
‡ Absent in disseminated infection in compromised hosts.
[18] Conditions that also cause right upper quadrant pain.

Transient ischemic attack.
Hypoglycemia.
Syncope.
Narcolepsy.
Migraine.
Paroxysmal vertigo.
Arrhythmias.
Drug reaction.

EPILEPSY MIMICS, PEDIATRIC PATIENT[84]

ICD-10CM # Varies with specific diagnosis

DISORDERS THAT MAY MIMIC CHILDHOOD EPILEPSY

Confused with Generalized Tonic–Clonic Seizures

Pallid syncope (reflex anoxic seizure).
Vasodepressor syncope (reflex anoxic seizure).
Cyanotic breath-holding attacks.
Collapsing attacks with cardiac dysrhythmias.
Cataplexy.

Confused with Generalized Absence Seizures

Behavioral staring attacks.
Complex partial (dyscognitive) seizures.
Tic disorder.

Confused with Complex Partial (Dyscognitive) Seizures

Self-stimulatory behavior, especially in children with autistic spectrum disorders.
Sleep walking.
Night terrors.
Temper tantrums with amnesia for the rage event.
Benign paroxysmal vertigo.
Migraine-related disorders.

Confused with Epileptic Myoclonus

Physiologic hypnagogic myoclonus.
Benign infantile sleep myoclonus.
Startle disease.

EPILEPSY SYNDROMES, AGE SPECIFIC[19]

ICD-10CM #	G40.90	Epilepsy, unspecified, not intractable
	G40.301	Generalized idiopathic epilepsy and epileptic syndromes, not intractable, with status epilepticus
	G40.40	Other generalized epilepsy and epileptic syndromes, not intractable

EPILEPSY SYNDROMES BY AGE OF ONSET

Neonatal

Benign familial neonatal epilepsy.
Early myoclonic encephalopathy.
Ohtahara syndrome.

Infancy

Epilepsy of infancy with migrating focal seizures.
West syndrome (infantile spasms, hypsarrhythmia; to be distinguished from benign myoclonus of early infancy, a nonepilepsy).
Myoclonic epilepsy in infancy (benign Dravet variant).
Benign infantile epilepsy.
Benign familial infantile epilepsy.
Severe myoclonic epilepsy of infancy (classic Dravet syndrome).
Myoclonic encephalopathy in nonprogressive disorders.

Childhood

Genetic epilepsy with febrile seizures plus (GEFS +; can begin in infancy).
Panayiotopoulos syndrome.
Epilepsy with myoclonic atonic (previously astatic) seizures (Doose syndrome).
Benign epilepsy with centrotemporal spikes (BECTS, or benign rolandic epilepsy).
Autosomal-dominant nocturnal frontal lobe epilepsy (ADNFLE).
Late-onset childhood occipital epilepsy (Gastaut syndrome).
Epilepsy with myoclonic absences (Tassinari syndrome).
Lennox–Gastaut syndrome.
Epileptic encephalopathy with continuous spike-and-wave during sleep (CSWS).
Landau–Kleffner syndrome (LKS).
Childhood absence epilepsy (pyknolepsy).
Generalized epilepsy with eyelid myoclonia (Jeavons syndrome).*

Adolescence–Adult

Juvenile absence epilepsy (JAE).
Juvenile myoclonic epilepsy (JME).
Epilepsy with generalized tonic-clonic seizures alone.
Progressive myoclonus epilepsies (PME).
Autosomal-dominant epilepsy with auditory features.
Other familial temporal lobe epilepsies.

Less Specific Age Relationship

Familial focal epilepsy with variable foci (childhood to adult).
Reflex epilepsies (e.g., photosensitive, audiogenic, or reading-induced seizures; may or may not coexist with spontaneous seizures).

EPISTAXIS

ICD-10CM # R04.0 Epistaxis

Trauma.
Medications (nasal sprays, NSAIDs, anticoagulants, antiplatelets).
Nasal polyps.
Cocaine use.
Coagulopathy (hemophilia, liver disease, DIC, thrombocytopenia).
Systemic disorders (hypertension, uremia).
Infections.
Anatomic malformations.
Rhinitis.
Nasal polyps.
Local neoplasms (benign and malignant).
Desiccation.
Foreign body.

*Not listed as a syndrome by ILAE but instead recognized under absence seizures with special features.

ERECTILE DYSFUNCTION, ORGANIC[72]

ICD-10CM # N52.9 Male erectile dysfunction, unspecified

Neurogenic abnormalities: somatic nerve neuropathy, CNS abnormalities.
Psychogenic causes: depression, performance anxiety, marital conflict.
Endocrine causes: hyperprolactinemia, hypogonadotropic hypogonadism, testicular failure, estrogen excess.
Trauma: pelvic fracture, prostate surgery, penile fracture.
Systemic disease: DM, renal failure, hepatic cirrhosis.
Medications: diuretics, antidepressants, H_2 blockers, exogenous hormones, alcohol, antihypertensives, nicotine abuse, finasteride, etc.
Structural abnormalities: Peyronie disease.

EROSIONS, GENITALIA

ICD-10CM # N36.8 Other specified disorders of urethra

Candidiasis.
Intraepithelial neoplasia.
Squamous cell carcinoma.
Lichen planus.
Pemphigus vulgaris.
Erythema multiforme.
Lichen sclerosus.
Bullous pemphigoid.
Extramammary Paget disease.
Impetigo.

ERYTHEMATOUS ANNULAR SKIN LESIONS

ICD-10CM # L53.8 Other specified erythematous conditions

Tinea corporis.
Warfarin plaques.
Erythema multiforme.
Erythema annulare.
Cutaneous lupus.
Cutaneous sarcoidosis.
Trauma.
Acute febrile neutrophilic dermatosis (Sweet syndrome).

ERYTHROCYTOSIS[45]

ICD-10CM # D75.0 Familial erythrocytosis

CAUSES OF ERYTHROCYTOSIS

Relative or Spurious Erythrocytosis (Normal Red Cell Mass)

Hemoconcentration secondary to dehydration (diarrhea, diaphoresis, diuretics, water deprivation, emesis, ethanol, hypertension, preeclampsia, pheochromocytoma, carbon monoxide intoxication).

True or Absolute Erythrocytosis

Polycythemia vera.
Primary congenital polycythemia.

Secondary erythrocytosis caused by:
- Congenital causes (e.g., activating mutation of erythropoietin receptor).
- Hypoxia caused by carbon monoxide poisoning, high oxygen affinity hemoglobin, high-altitude residence, chronic pulmonary disease, hypoventilation syndromes such as sleep apnea, right to left cardiac shunt, neurologic defects involving the respiratory center.

Nonhypoxic causes with pathologic erythropoietin production.
Renal disease (cysts, hydronephrosis, renal artery stenosis, focal glomerulonephritis, renal transplantation).
Tumors (renal cell cancer, hepatocellular carcinoma, cerebellar hemangioblastoma, uterine fibromyoma, adrenal tumors, meningioma, pheochromocytoma).
Drug-associated causes:
Androgen therapy.
- Exogenous erythropoietin growth factor therapy.

ERYTHRODERMA

ICD-10CM # L53.9 Erythematous condition, unspecified

Drug reaction (e.g., allopurinol, ampicillin, phenytoin, vancomycin, dapsone, omeprazole, carbamazepine).
Atopic dermatitis.
Psoriasis.
Contact dermatitis.
Idiopathic.
Pityriasis rubra.
Chronic actinic dermatitis.
Bullous pemphigoid.
Paraneoplastic.
Cutaneous T-cell lymphoma.
Connective tissue disease.
Hypereosinophilia syndrome.

ESOPHAGEAL PERFORATION[58]

ICD-10CM # K22.3 Perforation of esophagus
S27.819A Unspecified injury of esophagus (thoracic part), initial encounter

Trauma.
Caustic burns.
Iatrogenic.
Foreign bodies.
Spontaneous rupture (Boerhaave syndrome).
Postoperative breakdown of anastomosis.

ESOPHAGEAL STRICTURES[77]

ICD-10CM # Varies with specific diagnosis

BENIGN

Congenital
Esophageal atresia.
Tracheoesophageal fistula.
Web.

ACQUIRED

Peptic:
- Gastroesophageal reflux.
- Scleroderma.

Schatzki ring.
Caustic ingestion.
Drug-induced:
- Anticholinergic medications.
- Aspirin.
- Ferrous sulfate.
- Fosamax.
- Nonsteroidal antiinflammatory.
- Quinidine.
- Potassium supplements.
- Tetracycline.
- Vitamin C.

Eosinophilic esophagitis.
Iatrogenic:
- Variceal ligation/injection.
- Endoscopic mucosal resection.
- Ablation therapy (cryotherapy/radiofrequency).
- Postoperative (anastomotic).
- Radiation.
- Instrumentation.
- Nasogastric tube.

Infections:
- Fungal: moniliasis.
- Bacterial: syphilis.
- Mycobacterial: tuberculosis.

Granulomatous:
- Crohn disease.

Dermatosis:
- Epidermolysis bullosa dystrophica.
- Pemphigoid.
- Behçet syndrome.

MALIGNANT

Primary.
Secondary.

ESOPHAGEAL TUMORS, BENIGN[77]

ICD-10CM # Varies with specific diagnosis

CLASSIFICATION OF BENIGN ESOPHAGEAL TUMORS

Mucosa (First and Second Esophageal Ultrasound [EUS] Layers)
Squamous papilloma.
Fibrovascular polyp.
Retention cyst.
Submucosa (Third EUS Layer)
Lipoma.
Fibroma.
Neurofibroma.
Granular cell tumor.
Hemangiomas.
Salivary gland–type tumor.
Muscularis Propria (Fourth EUS Layer)
Leiomyoma.
Duplication cyst.
Periesophageal Tissue (Fifth EUS Layer)
Foregut cyst.

ESOPHAGITIS[58]

ICD-10CM # K20.9 Esophagitis, unspecified

INFECTIOUS

Candidiasis.
Cytomegalovirus.
Herpes simplex virus.
HIV infection, acute.

NONINFECTIOUS

Gastroesophageal reflux.
Mucositis from cancer chemotherapy.
Mucositis from radiation therapy.
Aphthous ulcers.

ESOPHAGUS, SYSTEMIC DISEASES[77]

ICD-10CM # Varies with specific diagnosis

SYSTEMIC DISEASES OF THE ESOPHAGUS

Connective Tissue Disorders
Scleroderma.
Systemic lupus erythematosus.
Polymyositis.
Dermatomyositis.
Mixed connective tissue disorder.
Raynaud phenomenon.
Allergic Disease
Eosinophilic esophagitis.
Metabolic Diseases
Amyloidosis.
Diabetes mellitus.
Hypothyroidism.
Hyperthyroidism.
Dermatologic Diseases
Epidermolysis bullosa.
Pemphigus vulgaris.
Pemphigoid.
Erythema multiforme.
Lichen planus.
Behçet disease.
Infectious Diseases
Histoplasmosis.
Tuberculosis.
Actinomycosis.
Immunocompromised host:
- Fungal: *Candida* species.
- Viral: herpes simplex, cytomegalovirus.
- Mycobacterial.
- Bacterial: *Streptococcus viridans, Staphylococcus,* bacilli, *Treponema pallidum.*
- Protozoal.

Miscellaneous Disorders
Sarcoidosis.
Crohn disease.

ESOTROPIA

ICD-10CM # H50.00 Unspecified esotropia
H50.43 Accommodative component in esotropia
H50.05 Alternating esotropia

Congenital.
Accommodative esotropia.
Myasthenia gravis.
Abducens palsy.
Pseudo-sixth nerve palsy.
Medial rectus entrapment (e.g., blowout fracture).
Posterior internuclear ophthalmoplegia.
Wernicke encephalopathy.
Thyroid myopathy.
Chiari malformation.

EXANTHEMS[65]

ICD-10CM # R21 Rash and other nonspecific skin eruption

Measles.
Rubella.
Erythema infectiosum (fifth disease).
Roseola exanthema.
Varicella.
Enterovirus.
Adenovirus.
Epstein-Barr virus.
Kawasaki disease.
Staphylococcal scalded skin.
Scarlet fever.
Meningococcemia.
Rocky Mountain spotted fever.

EYELID NEOPLASM

ICD-10CM # C44.101 Unspecified malignant neoplasm of skin of unspecified eyelid, including canthus

MALIGNANT

Melanoma.
Basal cell carcinoma.
Squamous cell carcinoma.
Bowen disease.
Sebaceous cell carcinoma.
Metastatic lymphoma/leukemia.

BENIGN

Melanocytic nevus.
Pilar, eccrine, or apocrine tumor.
Neurofibroma.
Keratosis.
Squamous papilloma.
Keratoacanthoma.

EYELID RETRACTION

ICD-10CM # H02.89 Other specified disorders of eyelid

Congenital.
Graves ophthalmopathy.
Myasthenia gravis.
Postsurgical.
Guillain-Barré syndrome.
Cerebellar disease.
Horizontal gaze palsy.
Partial palsy of superior rectus muscle.
Encephalitis.
Closed head injury.
Disseminated sclerosis.
Eye trauma.
Contact lens wear.
Proptosis.
Eyelid neoplasm.
Atopic dermatitis.
Herpes zoster ophthalmicus.
Botulinum toxin injection.
Cyclic oculomotor paralysis.
Spheroid wing meningioma.
Hepatic cirrhosis.
Down syndrome.
Essential hypertension.
Meningitis.
Paget disease of bone.

EYE PAIN

ICD-10CM # H57.13 Ocular pain, bilateral

Foreign body.
Herpes zoster.
Trauma.
Conjunctivitis.
Iritis.
Iridocyclitis.
Uveitis.
Blepharitis.
Ingrown lashes.
Orbital or periorbital cellulitis/abscess.
Sinusitis.
Headache.
Glaucoma.
Inflammation of lacrimal gland.
Tic douloureux.
Cerebral aneurysm.
Cerebral neoplasm.
Entropion.
Retrobulbar neuritis.
UV light.
Dry eyes.
Irritation or inflammation from eye drops, dust, cosmetics, etc.

FACIAL PAIN

ICD-10CM # G50.1 Atypical facial pain

Infection, abscess.
Postherpetic neuralgia.
Trauma, posttraumatic neuralgia.
Tic douloureux.
Cluster headache, "lower-half headache."
Geniculate neuralgia.
Anxiety, somatization syndrome.
Glossopharyngeal neuralgia.
Carotidynia.

FACIAL PARALYSIS[65]

ICD-10CM # G51.0 Bell palsy

INFECTION

Bacterial: otitis media, mastoiditis, meningitis, Lyme disease.
Viral: herpes zoster, mononucleosis, varicella, rubella, mumps, Bell palsy.
Mycobacterial: TB, meningitis, leprosy.
Miscellaneous: syphilis, malaria.

TRAUMA

Temporal bone fracture, facial laceration.
Surgery.

NEOPLASM

Malignant: squamous cell carcinoma, basal cell and adenocystic tumors, leukemia, parotid neoplasms, metastatic tumors.
Benign: facial nerve neuroma, vestibular schwannoma, congenital cholesteatoma.

IMMUNOLOGIC

Guillain-Barré syndrome, periarteritis nodosa.
Reaction to tetanus antiserum.

METABOLIC

Pregnancy.
Hypothyroidism.
DM.

FAILURE TO THRIVE

ICD-10CM # R62.50 Unspecified lack of expected normal physiological development in childhood

PSYCHOSOCIAL/BEHAVIORAL

Inadequate diet because of poverty/food insufficiency, errors in food preparation.
Poor parenting skills (lack of knowledge of sufficient diet).
Child/parent interaction problems (autonomy struggles, coercive feeding, maternal depression).
Food refusal.
Rumination.
Parental cognitive or mental health problems.
Child abuse or neglect; emotional deprivation.

NEUROLOGIC

Cerebral palsy.
Hypothalamic and other CNS tumors (diencephalic syndrome).
Neuromuscular disorders.
Neurodegenerative disorders.

RENAL

Recurrent urinary tract infection.
Renal tubular acidosis.
Renal failure.

ENDOCRINE

Diabetes mellitus.
Diabetes insipidus.
Hypothyroidism/hyperthyroidism.
Growth hormone deficiency.
Adrenal insufficiency.

GENETIC/METABOLIC/CONGENITAL

Sickle cell disease.
Inborn errors of metabolism (organic acidosis, hyperammonemia, storage disease).
Fetal alcohol syndrome.
Skeletal dysplasias.

Congenital.
Accommodative esotropia.
Myasthenia gravis.
Abducens palsy.
Pseudo-sixth nerve palsy.
Medial rectus entrapment (e.g., blowout fracture).
Posterior internuclear ophthalmoplegia.
Wernicke encephalopathy.
Thyroid myopathy.
Chiari malformation.

EXANTHEMS[65]

ICD-10CM # R21 Rash and other nonspecific skin eruption

Measles.
Rubella.
Erythema infectiosum (fifth disease).
Roseola exanthema.
Varicella.
Enterovirus.
Adenovirus.
Epstein-Barr virus.
Kawasaki disease.
Staphylococcal scalded skin.
Scarlet fever.
Meningococcemia.
Rocky Mountain spotted fever.

EYELID NEOPLASM

ICD-10CM # C44.101 Unspecified malignant neoplasm of skin of unspecified eyelid, including canthus

MALIGNANT

Melanoma.
Basal cell carcinoma.
Squamous cell carcinoma.
Bowen disease.
Sebaceous cell carcinoma.
Metastatic lymphoma/leukemia.

BENIGN

Melanocytic nevus.
Pilar, eccrine, or apocrine tumor.
Neurofibroma.
Keratosis.
Squamous papilloma.
Keratoacanthoma.

EYELID RETRACTION

ICD-10CM # H02.89 Other specified disorders of eyelid

Congenital.
Graves ophthalmopathy.
Myasthenia gravis.
Postsurgical.
Guillain-Barré syndrome.
Cerebellar disease.
Horizontal gaze palsy.
Partial palsy of superior rectus muscle.
Encephalitis.
Closed head injury.
Disseminated sclerosis.
Eye trauma.
Contact lens wear.
Proptosis.
Eyelid neoplasm.
Atopic dermatitis.
Herpes zoster ophthalmicus.
Botulinum toxin injection.
Cyclic oculomotor paralysis.
Spheroid wing meningioma.
Hepatic cirrhosis.
Down syndrome.
Essential hypertension.
Meningitis.
Paget disease of bone.

EYE PAIN

ICD-10CM # H57.13 Ocular pain, bilateral

Foreign body.
Herpes zoster.
Trauma.
Conjunctivitis.
Iritis.
Iridocyclitis.
Uveitis.
Blepharitis.
Ingrown lashes.
Orbital or periorbital cellulitis/abscess.
Sinusitis.
Headache.
Glaucoma.
Inflammation of lacrimal gland.
Tic douloureux.
Cerebral aneurysm.
Cerebral neoplasm.
Entropion.
Retrobulbar neuritis.
UV light.
Dry eyes.
Irritation or inflammation from eye drops, dust, cosmetics, etc.

FACIAL PAIN

ICD-10CM # G50.1 Atypical facial pain

Infection, abscess.
Postherpetic neuralgia.
Trauma, posttraumatic neuralgia.
Tic douloureux.
Cluster headache, "lower-half headache."
Geniculate neuralgia.
Anxiety, somatization syndrome.
Glossopharyngeal neuralgia.
Carotidynia.

FACIAL PARALYSIS[65]

ICD-10CM # G51.0 Bell palsy

INFECTION

Bacterial: otitis media, mastoiditis, meningitis, Lyme disease.
Viral: herpes zoster, mononucleosis, varicella, rubella, mumps, Bell palsy.
Mycobacterial: TB, meningitis, leprosy.
Miscellaneous: syphilis, malaria.

TRAUMA

Temporal bone fracture, facial laceration.
Surgery.

NEOPLASM

Malignant: squamous cell carcinoma, basal cell and adenocystic tumors, leukemia, parotid neoplasms, metastatic tumors.
Benign: facial nerve neuroma, vestibular schwannoma, congenital cholesteatoma.

IMMUNOLOGIC

Guillain-Barré syndrome, periarteritis nodosa.
Reaction to tetanus antiserum.

METABOLIC

Pregnancy.
Hypothyroidism.
DM.

FAILURE TO THRIVE

ICD-10CM # R62.50 Unspecified lack of expected normal physiological development in childhood

PSYCHOSOCIAL/BEHAVIORAL

Inadequate diet because of poverty/food insufficiency, errors in food preparation.
Poor parenting skills (lack of knowledge of sufficient diet).
Child/parent interaction problems (autonomy struggles, coercive feeding, maternal depression).
Food refusal.
Rumination.
Parental cognitive or mental health problems.
Child abuse or neglect; emotional deprivation.

NEUROLOGIC

Cerebral palsy.
Hypothalamic and other CNS tumors (diencephalic syndrome).
Neuromuscular disorders.
Neurodegenerative disorders.

RENAL

Recurrent urinary tract infection.
Renal tubular acidosis.
Renal failure.

ENDOCRINE

Diabetes mellitus.
Diabetes insipidus.
Hypothyroidism/hyperthyroidism.
Growth hormone deficiency.
Adrenal insufficiency.

GENETIC/METABOLIC/CONGENITAL

Sickle cell disease.
Inborn errors of metabolism (organic acidosis, hyperammonemia, storage disease).
Fetal alcohol syndrome.
Skeletal dysplasias.

Chromosomal disorders.
Multiple congenital anomaly syndromes (VATER [vertebral defects, imperforate anus, tracheoesophageal fistula, radial and renal dysplasia], CHARGE [coloboma, heart disease, atresia choanae, retarded growth and retarded development and/or CNS anomalies, genital hypoplasia, ear anomalies and/or deafness]).

GASTROINTESTINAL

Pyloric stenosis.
Gastroesophageal reflux.
Repair of tracheoesophageal fistula.
Malrotation.
Malabsorption syndromes.
Celiac disease.
Milk intolerance: lactose, protein.
Pancreatic insufficiency syndromes (cystic fibrosis).
Chronic cholestasis.
Inflammatory bowel disease.
Chronic congenital diarrhea states.
Short bowel syndrome.
Pseudoobstruction.
Hirschsprung disease.
Food allergy.

CARDIAC

Cyanotic heart lesions.
Congestive heart failure.
Vascular rings.

PULMONARY/RESPIRATORY

Severe asthma.
Cystic fibrosis; bronchiectasis.
Chronic respiratory failure.
Bronchopulmonary dysplasia.
Adenoid/tonsillar hypertrophy.
Obstructive sleep apnea.

MISCELLANEOUS

Collagen vascular disease.
Malignancy.
Primary immunodeficiency.
Transplantation.

INFECTIONS

Perinatal infection (TORCHES [toxoplasma, other, rubella, cytomegalovirus, herpes simplex]).
Occult/chronic infections.
Parasitic infestation.
Tuberculosis.
HIV.

FATIGUE

ICD-10CM #		
	R53.83	Other fatigue
	F48.0	Neurasthenia

Depression.
Anxiety, emotional stress.
Inadequate sleep.
Chronic fatigue syndrome.
Prolonged physical activity.
Pregnancy and postpartum period.
Anemia.
Hypothyroidism.
Medications (β-blockers, anxiolytics, antidepressants, sedating antihistamines, clonidine, methyldopa).
Viral or bacterial infections.
Sleep apnea syndrome.
Dieting.
Renal failure, CHF, COPD, liver disease.

FATIGUE, CHRONIC

ICD-10CM #		
	R53.83	Other fatigue
	F48.0	Neurasthenia

CHRONIC INFECTIONS

Hepatitis C.
Lyme disease.
Parasitic and fungal infections.
Tuberculosis.
Human immunodeficiency virus.
Xenotropic murine leukemia retrovirus.

SLEEP DISORDERS

Obstructive sleep apnea.
Restless leg syndrome.
Circadian rhythm disorder.
Upper airway resistance syndrome.
Narcolepsy/parasomnias.
Alpha-delta sleep disorder.

ENDOCRINE/METABOLIC DISORDERS

Addison disease.
Cushing syndrome.
Poorly controlled diabetes.
Thyroid disorders.
Hemochromatosis.
Hypopituitarism.
Diabetes insipidus.

GENERAL MEDICAL DISORDERS

Anemia (any cause).
Chronic renal/hepatic failure.
Malnutrition.
Medication side effects.
Chronic pain disorders.

PSYCHOLOGICAL

Mood disorders (depression, anxiety, bipolar).
Schizophrenia.
Posttraumatic stress disorder.
Anorexia nervosa/bulimia.
Childhood abuse and/or neglect.

CHRONIC INFLAMMATION

Rheumatoid arthritis.
Systemic lupus erythematosus.
Sjögren syndrome.
Polymyositis/dermatomyositis.
Vasculitis.
Sarcoidosis.

CARDIOPULMONARY

Congestive heart failure.
Neurally mediated hypotension.
Postural orthostatic tachycardia syndrome.
Pulmonary hypertension.
Chronic obstructive pulmonary disease.
Mitral valve prolapse.

GASTROINTESTINAL

Celiac disease.
Inflammatory bowel disease.
Autoimmune hepatitis.
Hepatic cirrhosis.

MALIGNANCY

Lymphoma and occult malignancies.
Postchemotherapy syndrome.

NEUROLOGIC DISORDERS

Multiple sclerosis.
Myasthenia gravis.
Muscular dystrophies.
Parkinson disease.
Early dementia.

LIFESTYLE FACTORS

Chronic overwork.
Persistent unresolved stress.
Inadequate exercise.
Morbid obesity (body mass index >40).
Alcoholism/drug abuse.

FATTY LIVER

ICD-10CM #		
	K76.0	Fatty (change of) liver, not elsewhere classified
	K76.89	Other specified diseases of liver

Obesity.
Alcohol abuse.
DM.
Acute fatty liver of pregnancy.
Medications (tetracycline, valproic acid, glucocorticoids, amiodarone, estrogen, methotrexate).
Reye syndrome.
Wilson disease.
Nonalcoholic steatosis.

FEVER, ABDOMINAL PAIN, JAUNDICE IN PEDIATRIC PATIENT[19]

ICD-10CM #		
	R50.9	Fever, unspecified

Cholangitis.
Cholecystitis.
Cholelithiasis.
Sepsis.
Hepatitis.
Choledochal cyst.
Pancreatitis.
Urinary tract infection.
Leptospirosis and other systemic infections with hepatic involvement.
Spontaneous perforation of common bile duct.
Biliary cyst.
Appendicitis.

FEVER AND CARDIOPULMONARY FAILURE[25]

ICD-10CM #		
	R50.9	Fever, unspecified

DIFFERENTIAL DIAGNOSIS OF FEVER AND RAPIDLY PROGRESSIVE CARDIOPULMONARY FAILURE

Bacterial Infection

Severe community-acquired pneumonia.
Meningitis, endocarditis.
Rickettsial disease (babesiosis, ehrlichiosis, Rocky Mountain spotted fever, scrub typhus, Mediterranean spotted fever).
Q-Fever (*Coxiella burnetii*).
Brucellosis.
Plague (*Yersinia pestis*).
Tularemia (*Francisella tularensis*).
Typhoid fever/salmonellosis.
Leptospirosis (*Leptospira interrogans*).
Anthrax.
Mycobacterial infections.

Viral Infections

Viral pneumonia (influenza, CMV, EBV, VZV, SARS).
Hantavirus.
Dengue fever and yellow fever.
Hemorrhagic fever (Lassa, Marburg, or Ebola viruses).

Fungal Infections

Coccidiomycosis.
Cryptococcus.
Histoplasmosis.
Blastomycosis.

Parasitic Infections

Malaria.
Leishmaniasis.
Schistosomiasis.
Strongyloides.

Noninfectious Causes

Inflammatory:
- Rapid-onset interstitial pneumonia (acute interstitial pneumonia, acute hypersensitivity pneumonitis).
- Acute eosinophilic pneumonia.
- ARDS due to other causes (inhalation injury, drug overdose, trauma).

Rheumatologic disorders:
- Wegener granulomatosis, Churg-Strauss disease, Goodpasture syndrome.
- Systemic lupus erythematosus, antiphospholipid syndrome.

Other:
- Malignancy, lymphoma, lymphoproliferative disease, leukemia.
- Pulmonary embolism, aortic dissection, acute myocardial infarction.
- Adrenal insufficiency, thyroid storm.

ARDS, Acute respiratory distress syndrome; *CMV,* Cytomegalovirus; *EBV,* Epstein-Barr virus; *SARS,* severe acute respiratory syndrome; *VZV,* varicella zoster virus.

FEVER AND JAUNDICE

ICD-10CM #		
	R50.9	Fever, unspecified
	R17	Unspecified jaundice

Bacterial sepsis.
Cholangitis.
Hepatic abscess.
Leptospirosis.
Malaria.
Viral hepatitis.
Yellow fever.

FEVER AND LYMPHADENOPATHY

ICD-10CM #		
	R59.9	Enlarged lymph nodes, unspecified
	R50.9	Fever, unspecified

REGIONAL

Cervical

Streptococci.
Tuberculosis.
Viral upper respiratory infection.

Peripheral

Bartonella henselae.
Herpesviruses.
Lymphoma.
Metastatic cancer.
Sporotrichosis.
Streptococci.

Inguinal

Chancroid.
Herpes.
Lymphogranuloma venereum.
Syphilis (primary).

GENERALIZED

Cytomegalovirus.
Epstein-Barr virus.
HIV.
Lymphoma.
Sarcoidosis.
Syphilis (secondary).
Toxoplasmosis.
Viral hepatitis.

FEVER AND RASH

ICD-10CM #		
	R21	Rash and other nonspecific skin eruption
	R21	Rash and other nonspecific skin eruption
	R50.9	Fever, unspecified

Drug hypersensitivity: penicillin, sulfonamides, thiazides, anticonvulsants, allopurinol.
Viral infection: measles, rubella, varicella, erythema infectiosum, roseola, enterovirus infection, viral hepatitis, infectious mononucleosis, acute HIV.
Other infections: meningococcemia, staphylococcemia, scarlet fever, typhoid fever, *Pseudomonas* bacteremia, Rocky Mountain spotted fever, Lyme disease, secondary syphilis, bacterial endocarditis, babesiosis, brucellosis, listeriosis.
Serum sickness.
Erythema multiforme.
Erythema marginatum.
Erythema nodosum.
SLE.
Dermatomyositis.
Allergic vasculitis.
Pityriasis rosea.
Herpes zoster.

FEVER AND RASH IN ICU[86]

ICD-10CM #		
	R21	Rash and other nonspecific skin eruption
	R50.9	Fever, unspecified

DIFFERENTIAL DIAGNOSTIC CLINICAL FEATURES OF FEVER AND RASH IN THE ICU

Rash with Shock

Infectious causes: toxic shock syndrome, meningococcemia, postsplenectomy sepsis, overwhelming *Staphylococcus aureus* bacteremia/acute bacterial endocarditis, arboviral hemorrhagic fevers, hemorrhagic smallpox, *Vibrio vulnificus*, gas gangrene, dengue fever.
Noninfectious cause: systemic lupus erythematosus (on steroids).

RASH WITH MENTAL CHANGES

Infectious causes: Rocky Mountain spotted fever, meningococcemia (with meningitis), *S. aureus* acute bacterial endocarditis, Chikungunya fever, typhus.
Noninfectious cause: systemic lupus erythematosus.

RASH WITH CONJUNCTIVAL SUFFUSION

Infectious causes: Rocky Mountain spotted fever, dengue fever, arboviral hemorrhagic fevers, toxic shock syndrome.
Noninfectious cause: adult Kawasaki disease.

RASH WITH RELATIVE BRADYCARDIA

Infectious causes: Rocky Mountain spotted fever, typhus, dengue fever, typhoid, arboviral hemorrhagic fevers.
Noninfectious cause: drug rash.

RASH WITH ABDOMINAL PAIN

Infectious causes: *V. vulnificus,* gas gangrene, *Clostridium sordelli,* scarlet fever.
Noninfectious causes: cholesterol emboli syndrome, systemic lupus erythematosus.

RASH ON PALMS AND SOLES

Infectious causes: Rocky Mountain spotted fever, toxic shock syndrome, chickenpox, smallpox, monkeypox, scarlet fever.
Noninfectious cause: drug rash.

RASH WITH DIARRHEA

Infectious causes: *V. vulnificus,* gas gangrene, toxic shock syndrome, dengue fever, arboviral hemorrhagic fevers.
Noninfectious cause: none.

RASH WITH EDEMA OF DORSUM OF HANDS/FEET

Infectious causes: Rocky Mountain spotted fever, toxic shock syndrome.
Noninfectious cause: adult Kawasaki disease.

RASH WITH BULLAE

Infectious causes: *V. vulnificus, S. aureus* complicated skin/skin structure infection, gas gangrene.
Noninfectious cause: none.

RASH WITH HEART MURMUR

Infectious cause: acute bacterial endocarditis.
Noninfectious cause: systemic lupus erythematosus.
Rash with gangrene of nose tip
Infectious cause: *S. aureus* acute bacterial endocarditis.
Noninfectious causes: systemic lupus erythematosus, vasculitis.

RASH WITH CEREBROVASCULAR ACCIDENT

Infectious causes: cholesterol emboli syndrome, *S. aureus* acute bacterial endocarditis.
Noninfectious cause: none.

RASH WITH SPLENOMEGALY

Infectious causes: Rocky Mountain spotted fever, typhus.
Noninfectious causes: systemic lupus erythematosus, adult Kawasaki disease.

RASH WITH DEAFNESS

Infectious causes: Rocky Mountain spotted fever, typhus, meningococcal meningitis.
Noninfectious cause: none.

RASH WITH HEPATOSPLENOMEGALY

Infectious causes: Rocky Mountain spotted fever, typhus.
Noninfectious cause: atypical measles.

RASH WITH HEPATOMEGALY

Infectious cause: typhus.
Noninfectious cause: none.

FEVER, AFTER TRAVEL TO THE TROPICS[3]

ICD-10CM # R50.81 Fever presenting with conditions classified elsewhere

CAUSES OF FEVER AFTER TRAVEL TO THE TROPICS

80% of Specific Infections Causing Fever (Includes Respiratory and Urinary Tract Infection)
Malaria.
Viral hepatitis.
Febrile illness unrelated to foreign travel.
Dengue fever.
Enteric fever (typhoid and paratyphoid fevers).
Other Causes
Gastroenteritis.
Rickettsia.
Leptospirosis.
Schistosomiasis.
Amebic liver abscess.
Tuberculosis.
Acute HIV infection.
Others.

FEVER, COMMON INFECTIOUS CAUSES[88]

ICD-10CM # R50.9 Fever, unspecified

CENTRAL NERVOUS SYSTEM

Meningitis:
- Encephalitis.
- Brain abscess.
- Epidural abscess.

HEAD AND NECK

Acute suppurative parotitis:
- Acute sinusitis.
- Parapharyngeal and retropharyngeal space infections.
- Acute suppurative otitis media.

CARDIOVASCULAR

Catheter-related infection:
- Endocarditis.

PULMONARY AND MEDIASTINAL

Pneumonia:
- Empyema.
- Mediastinitis.

HEPATOBILIARY AND GASTROINTESTINAL

Diverticulitis:
- Appendicitis.
- Peritonitis (spontaneous or secondary).
- Intraperitoneal abscess.
- Perirectal abscess.
- Infected pancreatitis.
- Acute cholecystitis.
- Cholangitis.
- Hepatic abscess.
- Acute viral hepatitis.

GENITOURINARY

Bacterial or fungal cystitis:
- Pyelonephritis.
- Perinephric abscess.
- Tubo-ovarian abscess.
- Endometritis.
- Prostatitis.

BREAST

Mastitis:
- Breast abscess.

CUTANEOUS AND MUSCULAR

Cellulitis:
- Suppurative wound infection.
- Necrotizing fasciitis.
- Bacterial myositis or myonecrosis.
- Herpes zoster.

OSSEOUS

Osteomyelitis.

FEVER, DRUG-INDUCED[34]

ICD-10CM # R50.2 Drug induced fever

SELECTED AGENTS ASSOCIATED WITH DRUG-INDUCED FEVER

Common
Antimicrobial:
- Amphotericin B.
- β-Lactams.
- Sulfonamides.

Cardiovascular:
- Procainamide.
- Quinidine.

CNS:
- Carbamazepine.
- Phenytoin.

Miscellaneous:
- Bleomycin.
- Interferon-α.
- Interleukin-2.

Less Common
Antimicrobial:
- Clindamycin.
- Fluoroquinolones.
- Rifampin.

Cardiovascular:
- Diltiazem.
- Hydralazine.

CNS:
- Haloperidol.
- Serotonin reuptake inhibitors.

Miscellaneous:
- Allopurinol.
- Cimetidine.
- Tacrolimus.

FEVER, HOSPITAL ASSOCIATED[34]

ICD-10CM # R50.2 Drug induced fever
R50.9 Fever, unspecified

SELECTED CAUSES OF HOSPITAL-ASSOCIATED FEVER

Common
Infectious:
- *Clostridium difficile* enterocolitis.
- Pneumonia.
- Surgical wound.
- Urinary tract.
- Vascular catheter.

Noninfectious:
- Drug-induced fever.
- Hematoma.
- Immediate postoperative state.
- Transfusion reaction.
- Venous thromboembolism.

Less Common
Infectious:
- Biliary tract disease.
- Endometritis.
- Intraabdominal abscess.
- Mediastinitis.
- Sinusitis.

Noninfectious:
- Adrenal insufficiency.
- Gout.
- Myocardial infarction.
- Organ infarction.
- Pancreatitis.

FEVER IN RETURNING TRAVELERS AND IMMIGRANTS[65]

ICD-10CM # R50.81 Fever presenting with conditions classified elsewhere

COMMON*

Acute respiratory tract infection (worldwide).
Gastroenteritis (worldwide) [foodborne, waterborne, fecal-oral].
Enteric fever, including typhoid (worldwide) [food, water].
Urinary tract infection (worldwide) [sexual contact].
Drug reactions [antibiotics, prophylactic agents, other] {rash frequent}.
Malaria (tropics, limited areas of temperate zones) [mosquitoes].
Arboviruses (Africa; tropics) [mosquitoes, ticks, mites].
Dengue (Asia, Caribbean, Africa) [mosquitoes].
Viral hepatitis (worldwide).
Hepatitis A (worldwide) [food, fecal-oral].
Hepatitis B (worldwide, especially Asia, sub-Saharan Africa) [sexual contact] {long incubation period}.
Hepatitis C (worldwide) [blood or sexual contact].
Hepatitis E (Asia, North Africa, Mexico, others) [food, water].
Tuberculosis (worldwide) [airborne, milk] {long period to symptomatic infection}.
Sexually transmitted diseases (worldwide) [sexual contact].

LESS COMMON*

Filariasis (Asia, Africa, South America) [biting insects] {long incubation period, eosinophilia}.
Measles (developing world) [airborne] {in susceptible individual}.
Amebic abscess (worldwide) [food].
Brucellosis (worldwide) [milk, cheese, food, animal contact].
Listeriosis (worldwide) [foodborne] {meningitis}.
Leptospirosis (worldwide) [animal contact, open fresh water] {jaundice, meningitis}.
Strongyloidiasis (warm and tropical areas) [soil contact] {eosinophilia}.
Toxoplasmosis (worldwide) [undercooked meat].

RARE

Relapsing fever (western Americas, Asia, northern Africa) [ticks, lice].
Hemorrhagic fevers (worldwide) [arthropod and nonarthropod transmitted].
Yellow fever (tropics) [mosquitoes] {hepatitis}.
Hemorrhagic fever with renal syndrome (Europe, Asia, North America) [rodent urine] {renal impairment}.
Hantavirus pulmonary syndrome (western North America, other) [rodent urine] {respiratory distress syndrome}.
Lassa fever (Africa) [rodent excreta, person to person] {high mortality rate}.
Other: chikungunya, Rift Valley, Ebola-Marburg, etc. (various) [insect bites, rodent excreta, aerosols, person to person] {often severe}.
Rickettsial infections {rashes and eschars}.
Leishmaniasis, visceral (Middle East, Mediterranean, Africa, Asia, South America) [biting flies] {long incubation period}.
Acute schistosomiasis (Africa, Asia, South America, Caribbean) [fresh water].
Chagas disease (South and Central America) [reduviid bug bites] {often asymptomatic}.
African trypanosomiasis (Africa) [tsetse fly bite] {neurologic syndromes, sleeping sickness}.
Bartonellosis (South America) [sandfly bite] {skin nodules}.
HIV infection/AIDS (worldwide) [sexual and blood contact].
Trichinosis (worldwide) [undercooked meat] {eosinophilia}.
Plague (temperate and tropical plains) [animal exposures and fleas].
Tularemia (worldwide) [animal contact, fleas, aerosols] {ulcers, lymph nodes}.
Anthrax (worldwide) [animal, animal product contact] {ulcers}.
Lyme disease (North America, Europe) [tick bites] {arthritis, meningitis, cardiac abnormalities}.

*Diagnoses for which particular symptoms are indicative are in *italics*. Exposure to regions of the world that are most likely to be significant to the diagnosis are presented in (parentheses). Vectors, risk behaviors, and sources associated with acquisition are presented in [brackets]. Special clinical characteristics are listed within {braces}.

FEVER, NONINFECTIOUS CAUSES[7]

ICD-10CM # R50.9 Fever, unspecified

DIFFERENTIAL DIAGNOSIS—NONINFECTIOUS CAUSES OF FEVER

Critical Diagnoses
Acute myocardial infarction.
Pulmonary embolism/infarction.
Intracranial hemorrhage.
Cerebrovascular accident.
Neuroleptic-malignant syndrome.
Thyroid storm.
Acute adrenal insufficiency.
Transfusion reaction.
Pulmonary edema.
Emergent Diagnoses
Congestive heart failure.
Dehydration.
Recent seizure.
Sickle cell disease.
Transplant rejection.
Pancreatitis.
Deep vein thrombosis.
Nonemergent Diagnoses
Drug fever.
Malignancy.
Gout.
Sarcoidosis.
Crohn disease.
Postmyocardiotomy syndrome.

FEVER OF UNKNOWN ORIGIN, PEDIATRIC PATIENT[19]

ICD-10CM # R50.9 Fever, unspecified

INFECTIOUS DISEASES

Bacterial
Bacterial endocarditis.
Brucellosis.
Cat-scratch disease.
Leptospirosis.
Liver abscess.
Mastoiditis (chronic).
Osteomyelitis.
Pelvic abscess.
Perinephric abscess.
Pyelonephritis.
Salmonellosis.
Sinusitis.
Subdiaphragmatic abscess.
Tuberculosis.
Tularemia.
Viral
Adenovirus.
Arboviruses.
Cytomegalovirus.
Epstein-Barr virus (infectious mononucleosis).
Hepatitis viruses.
Chlamydial
Lymphogranuloma venereum.
Psittacosis.
Rickettsial
Q fever.
Rocky Mountain spotted fever.
Fungal
Blastomycosis (nonpulmonary).
Histoplasmosis (disseminated).
Parasitic
Malaria.
Toxoplasmosis.
Visceral larva migrans.
Unclassified
Sarcoidosis.
Collagen Vascular Diseases
Juvenile rheumatoid arthritis.
Polyarteritis nodosa.
Systemic lupus erythematosus.
Malignancies
Hodgkin disease.
Leukemia and lymphoma.
Neuroblastoma.
Miscellaneous
Central diabetes insipidus.
Drug fever.
Ectodermal dysplasia.
Factitious fever.
Familial dysautonomia.
Granulomatous colitis.
Hemophagocytic lymphohistiocytosis.

Infantile cortical hyperostosis.
Kikuchi-Fujimoto disease.
Nephrogenic diabetes insipidus.
Pancreatitis.
Periodic fever.
Serum sickness.
Thyrotoxicosis.
Ulcerative colitis.

FEVER, POSTPARTUM[1]

ICD-10CM # R50.9 Fever, unspecified

MOST COMMON

Metritis.
Urinary tract infection.
Pneumonia.
Wound infection.
Mastitis.
Superficial or deep vein thrombosis.

MOST THREATENING

Toxic shock syndrome.
Necrotizing fasciitis.
Pelvic phlegmon.
Pelvic abscess.
Peritonitis.
Septic pelvic thrombosis.
Breast abscess.

FEVER, PERIODIC[29]

ICD-10CM # R50.9 Fever, unspecified

HEREDITARY

Nonhereditary
Infectious
Hidden infectious focus (e.g., aortoenteric fistula, Caroli disease).
Recurrent reinfection (e.g., chronic meningococcemia, host defense defect).
Specific infection (e.g., Whipple disease, malaria).
Noninfectious inflammatory disorder, e.g.:
- Adult-onset Still disease.
- Juvenile chronic rheumatoid arthritis.
- Periodic fever, aphthous stomatitis, pharyngitis, and adenitis.
- Schnitzler syndrome.
- Behçet syndrome.
- Crohn disease.
- Sarcoidosis.
- Extrinsic alveolitis.
- Humidifier lung, polymer fume fever.
- Neoplastic.

Lymphoma (e.g., Hodgkin disease, angioimmunoblastic lymphoma).
Solid tumor (e.g., pheochromocytoma, myxoma, colon carcinoma).
Vascular (e.g., recurrent pulmonary embolism)
Hypothalamic
Psychogenic periodic fever.
Factitious or fraudulent.

FEVER, PEDIATRIC, ACUTE[1]

ICD-10CM # R50.9 Fever, unspecified

COMMON VIRAL INFECTIONS

Central Nervous System
Meningitis.
Encephalitis.
Tumor.
Brain abscess.
Head, Ears, Eyes, Nose, and Throat
Otitis media.
Pharyngitis.
Retropharyngeal abscess.
Peritonsillar abscess.
Lateral pharyngeal wall abscess.
Stomatitis.
Influenza.
Sinusitis.
Parotitis.
Cervical adenitis.
Periorbital cellulitis.
Orbital cellulitis or abscess.
Respiratory System
Bronchiolitis.
Croup.
Epiglottitis.
Pneumonia.
Upper respiratory infection.
Cardiovascular System
Myocarditis.
Pericarditis.
Endocarditis.
Genitourinary System
Urinary tract infection.
Tuboovarian abscess.
Gastrointestinal Tract
Acute viral gastroenteritis.
Bacterial enteritis.
Appendicitis.
Focal Soft Tissue Infections
Cellulitis.
Musculoskeletal System
Osteomyelitis.
Septic arthritis.
Rheumatologic Disorders
Acute rheumatic fever.
Juvenile rheumatoid arthritis.
Henoch-Schönlein purpura.
Vasculitis
Behçet syndrome.
Malignancy
Leukemia.
Lymphoma.
Sarcoma.
Systemic Illness
Bacteremia.
Viremia.
Sepsis.
Kawasaki disease.
Toxic shock syndrome.
Rocky Mountain spotted fever.
Meningococcemia.

MISCELLANEOUS DISORDERS

Toxicologic
Anticholinergic toxidromes.
Salicylate overdose.
Amphetamine.
Cocaine.
Endocrine
Thyrotoxicosis.

FEVER, RECURRENT OR PERIODIC, IN CHILDREN[53]

ICD-10CM # R50.2 Drug induced fever
R50.9 Fever, unspecified

INFECTIOUS DISEASES

Brucellosis.
Rat-bite fever.
Relapsing fever.

RHEUMATIC DISEASES

Juvenile idiopathic arthritis (systemic onset).
Behçet disease.
Systemic lupus erythematosus.
Relapsing polychondritis.
Crohn disease.

HEREDITARY AUTOINFLAMMATORY SYNDROMES

Familial Mediterranean fever (FMF).
Cryopyrinopathies:
- Familial cold autoinflammatory syndrome (FCAS).
- Muckle-Wells syndrome (MWS).
- Chronic infantile neurologic cutaneous and articular (CINCA) syndrome, also called neonatal-onset multisystem inflammatory disease (NOMID).

Tumor necrosis factor receptor–associated periodic syndrome (TRAPS).
Hyperimmunoglobulinemia D with periodic fever syndrome (HIDS).

CYCLIC HEMATOPOIESIS

Hereditary form.
Acquired form.

IDIOPATHIC CONDITIONS

Periodic fever with aphthous stomatitis, pharyngitis, and adenitis (PFAPA).

FEVER WITH MACULOPAPULAR OR PETECHIAL RASH[69]

ICD-10CM # R21 Rash and nonspecific skin eruption
ICD-10CM # R50.9 Fever, unspecified

DIFFERENTIAL DIAGNOSIS OF FEVER WITH MACULOPAPULAR OR PETECHIAL RASH

Rocky Mountain spotted fever.
Meningococcal disease.
Enteroviral infection (echovirus and coxsackievirus).
Human herpesvirus 6 infection (roseola).
Human parvovirus B19 infection (fifth disease).
Epstein-Barr virus infection.
Disseminated gonococcal infection.
Murine typhus.
Ehrlichiosis.
Group A streptococcal pharyngitis.
Mycoplasma pneumoniae Infection.
Leptospirosis.
Secondary syphilis.

Kawasaki disease.
Thrombotic thrombocytopenic purpura (TTP).
Drug reactions.
Immune complex–mediated illness.
Toxic shock syndrome.
Erythema multiforme.
Stevens-Johnson syndrome.

FEVERS PRONE TO RELAPSE[42]

ICD-10CM #		
	R50.9	Fever, unspecified

Infectious Causes

Relapsing fever (*Borrelia recurrentis*).
Q fever (*Coxiella burnetii*).
Typhoid fever (*Salmonella typhi*).
Syphilis (*Treponema pallidum*).
Tuberculosis.
Histoplasmosis.
Coccidioidomycosis.
Blastomycosis.
Melioidosis (*Pseudomonas pseudomallei*).
Lymphocytic choriomeningitis (LCM) infection.
Dengue fever.
Yellow fever.
Chronic meningococcemia.
Colorado tick fever.
Leptospirosis.
Brucellosis.
Oroya fever (*Bartonella bacilliformis*).
Acute rheumatic fever.
Rat-bite fever (*Spirillum minus*).
Visceral leishmaniasis.
Lyme disease (*Borrelia burgdorferi*).
Malaria.
Babesiosis.
Noninfluenza respiratory viral infection.
Epstein-Barr virus infection.

Noninfectious Causes

Behçet disease.
Crohn disease.
Weber-Christian disease (panniculitis).
Leukoclastic angiitis syndromes.
Sweet syndrome.
Systemic lupus erythematosus and other autoimmune disorders.

Periodic Fever Syndromes

Familial Mediterranean fever.
Cyclic neutropenia.
Periodic fever, aphthous stomatitis, pharyngitis, and adenopathy (PFAPA).
Hyper–immunoglobulin D syndrome.
Hibernian fever (tumor necrosis factor superfamily immunoglobulin A–associated syndrome [TRAPS]).
Muckle-Wells syndrome.
Others.

FINGER LESIONS, INFLAMMATORY

ICD-10CM #		
	B08.8	Other specified viral infections characterized by skin and mucous membrane lesions
	L03.0	Cellulitis of finger and toe

Paronychia.
Herpes simplex type 1 (herpetic whitlow).
Dyshidrotic eczema (pompholyx).
Herpes zoster.
Bacterial endocarditis (Osler nodes).
Psoriatic arthritis.

FLACCID PARALYSIS, ACUTE, DIFFERENTIAL DIAGNOSIS[53]

ICD-10CM #		
	G83.9	Paralytic syndrome, unspecified

Brain stem stroke.
Brain stem encephalitis.
Acute anterior poliomyelitis.
  Caused by poliovirus.
  Caused by other neurotropic viruses.
Acute myelopathy.
  Space-occupying lesions.
  Acute transverse myelitis.
Peripheral neuropathy.
  Guillain-Barré syndrome.
  Post-rabies vaccine neuropathy.
  Diphtheritic neuropathy.
  Heavy metals, biologic toxins, or drug intoxication.
  Acute intermittent porphyria.
  Vasculitic neuropathy.
  Critical illness neuropathy.
  Lymphomatous neuropathy.
Disorders of neuromuscular transmission.
  Myasthenia gravis.
  Biologic or industrial toxins.
  Tic paralysis.
Disorders of muscle.
  Hypokalemia.
  Hypophosphatemia.
  Inflammatory myopathy.
  Acute rhabdomyolysis.
  Trichinosis.
  Periodic paralyses.

FLATULENCE AND BLOATING[76]

ICD-10CM #		
	R14.0	Abdominal distension (gaseous)
	R14.1	Gas pain
	R14.2	Eructation
	R14.3	Flatulence

Ingestion of nonabsorbable carbohydrates.
Ingestion of carbonated beverages.
Malabsorption: pancreatic insufficiency, biliary disease, celiac disease, bacterial overgrowth in small intestine.
Lactase deficiency.
Irritable bowel syndrome.
Anxiety disorders.
Food poisoning, giardiasis.

FLUSHING[63]

ICD-10CM #		
	R23.2	Flushing

Physiologic flushing: menopause, ingestion of monosodium glutamate (Chinese restaurant syndrome), ingestion of hot drinks.
Drugs: alcohol (with or without disulfiram, metronidazole, or chlorpropamide), nicotinic acid, diltiazem, nifedipine, levodopa, bromocriptine, vancomycin, amyl nitrate.
Neoplastic disorders: carcinoid syndrome, VIPoma syndrome, medullary carcinoma of thyroid, systemic mastocytosis, basophilic chronic myelocytic leukemia, renal cell carcinoma.
Anxiety.
Agnogenic flushing.

FOLATE DEFICIENCY[45]

ICD-10CM #		
	D52.0	Dietary folate deficiency anemia
	D52.1	Drug-induced folate deficiency anemia
	D52.8	Other folate deficiency anemias
	D52.9	Folate deficiency anemia, unspecified

ETIOPATHOPHYSIOLOGIC CLASSIFICATION OF FOLATE DEFICIENCY

Nutritional causes:
  Decreased dietary intake:
    Poverty and famine.
    Institutionalized individuals (e.g., psychiatric, nursing homes), chronic debilitating disease.
    Prolonged feeding of infants with goat's milk, special slimming diets or food fads (i.e., folate-rich foods not consumed), cultural or ethnic cooking techniques (i.e., food folate destroyed).
  Decreased diet and increased requirements:
    Physiologic (e.g., pregnancy and lactation, prematurity, hyperemesis gravidarum, infancy).
    Pathologic (e.g., intrinsic hematologic diseases involving hemolysis with compensatory erythropoiesis, abnormal hematopoiesis, or bone marrow infiltration with malignant disease and dermatologic disease such as psoriasis).
Folate malabsorption:
  With normal intestinal mucosa:
    Some drugs (controversial).
    Congenital folate malabsorption (rare).
    With mucosal abnormalities (e.g., tropical and nontropical sprue, regional enteritis).
Defective cellular folate uptake:
  Familial aplastic anemia (rare).
  Acute cerebral folate deficiency.
Inadequate cellular use:
  Folate antagonists (e.g., methotrexate).
  Hereditary enzyme deficiencies involving folate.
Drugs:
  Multiple effects on folate metabolism (e.g., alcohol, sulfasalazine, triamterene, pyrimethamine, trimethoprim-sulfamethoxazole, diphenylhydantoin, barbiturates).
Acute folate deficiency:
  Intensive care unit setting.
  Uncertain origin.

FOOT AND ANKLE PAIN[27]

ICD-10CM #		
	M25.5	Pain in joint
	M25.9	Joint disorder, unspecified

TENDON, LIGAMENT, AND MUSCLE

Gastrocnemius-soleus strain.
Plantaris rupture.
Anterior talofibular ligament tear.
Calcaneofibular ligament tear.
Deltoid ligament tear.
Anterolateral impingement due to complete tear of anterior talofibular ligament and anterior inferior tibiofibular ligament.
Syndesmotic impingement due to tear of syndesmosis.
Sinus tarsi syndrome (lateral hindfoot pain and instability due to injury of contents of the sinus and tarsal tunnel).
Achilles tendinitis.
Achilles rupture.
Plantar fasciitis.
Posterior tibial tendon dysfunction.
Flexor hallucis longus dysfunction.
Tibialis anterior tendon tear.
Peroneus brevis tendon tear.

BONE

Fracture of talus.
Calcaneal fracture.
Navicular fractures.
Lisfranc fracture-dislocation (fracture of the first metatarsal base with dislocation of medial cuneiform).
Metatarsal stress fracture.
Freiberg infraction (sclerosis and flattening of the second metatarsal head due to trauma or microtrauma).
Avascular necrosis of the talus.
Fracture of the phalanges.
Fracture of the sesamoids.
Sesamoiditis.
Metatarsalgia.

JOINT

Osteoarthritis.
Gout.
Rheumatoid arthritis.
Other inflammatory arthritides.
Charcot joint.
Osteochondral lesion of the talus.

PERIARTICULAR STRUCTURES

Shin splint (periosteal avulsion and periostitis at the insertion of the medial soleus due to repetitive overuse, such as in running and hiking).
Hallux rigidus.
Hallux valgus.
Ingrown toenail.
Toe deformities.
Turf toe (sprain of the first metatarsophalangeal joint due to hyperextension forces).
Plantar fasciitis.
Plantar fibromatosis.

NERVES

Anterior tarsal tunnel syndrome (involvement of deep peroneal nerve under the superficial fascia of the ankle).
Morton neuroma.

VESSELS

Atherosclerosis.
Compartment syndrome.

REFERRED PAIN

Complex regional pain syndrome.

FOOT AND ANKLE PAIN, IN DIFFERENT AGE GROUPS[18]

ICD-10CM # M25.579 Pain in unspecified ankle and joints of unspecified foot

COMMON CAUSES OF FOOT AND ANKLE PAIN IN DIFFERENT AGE GROUPS

Childhood (2-10 yr)
Intraarticular
Club foot.
Congenital midfoot and forefoot deformities.
Septic arthritis.
Periarticular
Osteomyelitis.
Adolescence (10-18 yr)
Intraarticular
Arch disorders (pes cavus, pes planus).
Periarticular
Osteomyelitis.
Tumors.
Early Adulthood (18-30 yr)
Intraarticular
Metatarsalgia.
Hallux valgus.
Hallux rigidus.
Osteochondritis.
Accessory ossicles.
Periarticular
Achilles tendonitis.
Achilles tendon rupture.
Fasciitis.
Referred
Lumbar spine.
Knee.
Adulthood (30-50 yr)
Intraarticular
Osteoarthritis.
Inflammatory arthritis.
Gout.
Metatarsalgia.
Hallux valgus.
Hallux rigidus.
Osteochondritis.
Accessory ossicles.
Periarticular
Ischemic foot pain.
Diabetes.
Bursitis.
Tendonitis.
Plantar fasciitis.
Corns.
Referred
Lumbar spine.
Knee.
Old Age (>50 yr)
Intraarticular
Osteoarthritis.
Inflammatory arthritis.
Gout.
Metatarsalgia.
Hallux valgus.
Hallux rigidus.
Periarticular
Ischemic foot pain.
Diabetes.
Bursitis.
Tendonitis.
Plantar fasciitis.
Corns.
Referred
Lumbar spine.
Knee.

FOOT DERMATITIS

ICD-10CM # B35.3 Tinea pedis
K25 Unspecified contact dermatitis

Tinea pedis.
Dyshidrotic eczema.
Tylosis (mechanically induced hyperkeratosis, fissuring, and dryness).
Allergic contact dermatitis.
Psoriasis.
Peripheral vascular insufficiency.
Neuropathic foot ulcers (DM, poorly fitting shoes).
Acquired plantar keratoderma.
Sézary syndrome.

FOOTDROP

ICD-10CM # M21.379 Foot drop, unspecified foot

Peripheral neuropathy.
L5 radiculopathy.
Peroneal nerve compression.
Sciatic nerve palsy.
Scapuloperoneal syndromes.
Spasticity.
Peroneal nerve compression.
Myopathy.
Dystonia.

FOOT LESION, ULCERATING

ICD-10CM # S90.929A Unspecified superficial injury of unspecified foot, initial encounter
S90.933A Unspecified superficial injury of unspecified great toe, initial encounter
S90.936A Unspecified superficial injury of unspecified lesser toe(s), initial encounter
L08.89 Other specified local infections of the skin and subcutaneous tissue

Cellulitis.
Plantar wart.
Squamous cell carcinoma.
Actinomycosis (Madura foot).
Plantar fibromatosis.
Pseudoepitheliomatous hyperplasia.

FOOT PAIN

ICD-10CM #		
	M25.579	Pain in unspecified ankle and joints of unspecified foot

Trauma (fractures, musculoskeletal and ligamentous strain).
Inflammation (plantar fasciitis, Achilles tendonitis or bursitis, calcaneal apophysitis).
Arterial insufficiency, Raynaud phenomenon, thromboangiitis obliterans.
Gout, pseudogout.
Calcaneal spur.
Infection (cellulitis, abscess, lymphangitis, gangrene).
Decubitus ulcer.
Paronychia, ingrown toenail.
Thrombophlebitis, postphlebitic syndrome.

FOOT PAIN BY AGE[53]

ICD-10CM #		
	M25.579	Pain in unspecified ankle and joints of unspecified foot

0 TO 6 YEARS

Poorly fitting shoes.
Foreign body.
Fracture.
Osteomyelitis.
Leukemia.
Puncture wound.
Drawing of blood.
Dactylitis.
Juvenile rheumatoid arthritis (JRA).

6 TO 12 YEARS

Poorly fitting shoes.
Sever disease.
Enthesopathy (JRA).
Foreign body.
Accessory navicular.
Tarsal coalition.
Ewing sarcoma.
Hypermobile flatfoot.
Trauma (sprains, fractures).
Puncture wound.

12 TO 20 YEARS

Poorly fitting shoes.
Stress fracture.
Foreign body.
Ingrown toenail.
Metatarsalgia.
Plantar fasciitis.
Osteochondroses (avascular necrosis).
Freiberg infarction.
Köhler disease.
Achilles tendinitis.
Trauma (sprains).
Plantar warts.
Tarsal coalition.

FOREARM AND HAND PAIN

ICD-10CM #		
	S59.809A	Other specified injuries of unspecified elbow, initial encounter
	S59.919A	Unspecified injury of unspecified forearm, initial encounter
	S69.80XA	Other specified injuries of unspecified wrist, hand and finger(s), initial encounter
	S69.90XA	Unspecified injury of unspecified wrist, hand and finger(s), initial encounter

Epicondylitis.
Tenosynovitis.
Osteoarthritis.
Cubital tunnel syndrome.
Carpal tunnel syndrome.
Trauma.
Herpes zoster.
Peripheral vascular insufficiency.
Infection (cellulitis, abscess).

FOREARM FRACTURES[3]

ICD-10CM #		
	S52	Fracture of forearm

TRAUMATIC

Wrist sprain, elbow sprain.
Ligamentous injuries, forearm contusions, hematomas.
Dislocations of the elbow or wrist (including nursemaid's elbow).

INFECTIOUS

Cellulitis of the forearm, abscesses.
Necrotizing fasciitis.

VASCULAR

Acute arterial occlusion.
Venous thrombosis.

NEUROLOGIC

Neurapraxias, carpal tunnel syndrome.
Systemic neurologic syndromes involving the nerves of the upper extremities.

ARTHRITIS

Septic joint, gonococcal arthritis, rheumatoid arthritis, osteoarthritis.
Pseudogout, gout.
Systemic lupus erythematosus, rheumatic fever, viral syndrome.
Reiter syndrome, Lyme disease, serum sickness.

OTHER

Olecranon bursitis, soft tissue masses.
Normal growth plates, nutrient vessels.As cuptiust re mo et imus es doluptibus dolupta doloreperis voluptam etur acium quae ipiet

GAIT ABNORMALITY

ICD-10CM #		
	R26.0	Ataxic gait
	R26.1	Paralytic gait
	R26.89	Other abnormalities of gait and mobility
	R26.9	Unspecified abnormalities of gait and mobility

Parkinsonism.
Degenerative joint disease (hips, back, knees).
Multiple sclerosis.
Trauma, foot pain.
CVA.
Cerebellar lesions.
Infections (tabes, encephalitis, meningitis).
Sensory ataxia.
Dystonia, cerebral palsy, neuromuscular disorders.
Metabolic abnormalities.

GALACTORRHEA[65]

ICD-10CM #		
	N64.3	Galactorrhea not associated with childbirth

Prolonged suckling.
Drugs (INH, phenothiazines, reserpine derivatives, amphetamines, spironolactone and tricyclic antidepressants).
Major stressors (surgery, trauma).
Hypothyroidism.
Pituitary tumors.

GALLBLADDER SONOGRAPHIC NON-VISUALIZATION[74]

ICD-10CM #	
	Varies with specific diagnosis

CAUSES OF SONOGRAPHIC NON-VISUALIZATION OF GALLBLADDER

Previous cholecystectomy.
Physiologic contraction.
Fibrosed gallbladder duct—chronic cholecystitis.
Air-filled gallbladder or emphysematous cholecystitis.
Tumefactive sludge.
Agenesis of gallbladder.
Ectopic location.

GALLBLADDER WALL THICKENING[74]

ICD-10CM #	
	Varies with specific diagnosis

CAUSES OF GALLBLADDER WALL THICKENING

Generalized Edematous States

Congestive heart failure.
Renal failure.
End-stage cirrhosis.
Hypoalbuminemia.

Inflammatory Conditions

Primary:
- Acute cholecystitis.
- Cholangitis.

FOOT PAIN

ICD-10CM #		
	M25.579	Pain in unspecified ankle and joints of unspecified foot

Trauma (fractures, musculoskeletal and ligamentous strain).
Inflammation (plantar fasciitis, Achilles tendonitis or bursitis, calcaneal apophysitis).
Arterial insufficiency, Raynaud phenomenon, thromboangiitis obliterans.
Gout, pseudogout.
Calcaneal spur.
Infection (cellulitis, abscess, lymphangitis, gangrene).
Decubitus ulcer.
Paronychia, ingrown toenail.
Thrombophlebitis, postphlebitic syndrome.

FOOT PAIN BY AGE[53]

ICD-10CM #		
	M25.579	Pain in unspecified ankle and joints of unspecified foot

0 TO 6 YEARS

Poorly fitting shoes.
Foreign body.
Fracture.
Osteomyelitis.
Leukemia.
Puncture wound.
Drawing of blood.
Dactylitis.
Juvenile rheumatoid arthritis (JRA).

6 TO 12 YEARS

Poorly fitting shoes.
Sever disease.
Enthesopathy (JRA).
Foreign body.
Accessory navicular.
Tarsal coalition.
Ewing sarcoma.
Hypermobile flatfoot.
Trauma (sprains, fractures).
Puncture wound.

12 TO 20 YEARS

Poorly fitting shoes.
Stress fracture.
Foreign body.
Ingrown toenail.
Metatarsalgia.
Plantar fasciitis.
Osteochondroses (avascular necrosis).
Freiberg infarction.
Köhler disease.
Achilles tendinitis.
Trauma (sprains).
Plantar warts.
Tarsal coalition.

FOREARM AND HAND PAIN

ICD-10CM #		
	S59.809A	Other specified injuries of unspecified elbow, initial encounter
	S59.919A	Unspecified injury of unspecified forearm, initial encounter
	S69.80XA	Other specified injuries of unspecified wrist, hand and finger(s), initial encounter
	S69.90XA	Unspecified injury of unspecified wrist, hand and finger(s), initial encounter

Epicondylitis.
Tenosynovitis.
Osteoarthritis.
Cubital tunnel syndrome.
Carpal tunnel syndrome.
Trauma.
Herpes zoster.
Peripheral vascular insufficiency.
Infection (cellulitis, abscess).

FOREARM FRACTURES[3]

ICD-10CM #		
	S52	Fracture of forearm

TRAUMATIC

Wrist sprain, elbow sprain.
Ligamentous injuries, forearm contusions, hematomas.
Dislocations of the elbow or wrist (including nursemaid's elbow).

INFECTIOUS

Cellulitis of the forearm, abscesses.
Necrotizing fasciitis.

VASCULAR

Acute arterial occlusion.
Venous thrombosis.

NEUROLOGIC

Neurapraxias, carpal tunnel syndrome.
Systemic neurologic syndromes involving the nerves of the upper extremities.

ARTHRITIS

Septic joint, gonococcal arthritis, rheumatoid arthritis, osteoarthritis.
Pseudogout, gout.
Systemic lupus erythematosus, rheumatic fever, viral syndrome.
Reiter syndrome, Lyme disease, serum sickness.

OTHER

Olecranon bursitis, soft tissue masses.
Normal growth plates, nutrient vessels.As cuptiust re mo et imus es doluptibus dolupta doloreperis voluptam etur acium quae ipiet

GAIT ABNORMALITY

ICD-10CM #		
	R26.0	Ataxic gait
	R26.1	Paralytic gait
	R26.89	Other abnormalities of gait and mobility
	R26.9	Unspecified abnormalities of gait and mobility

Parkinsonism.
Degenerative joint disease (hips, back, knees).
Multiple sclerosis.
Trauma, foot pain.
CVA.
Cerebellar lesions.
Infections (tabes, encephalitis, meningitis).
Sensory ataxia.
Dystonia, cerebral palsy, neuromuscular disorders.
Metabolic abnormalities.

GALACTORRHEA[65]

ICD-10CM #		
	N64.3	Galactorrhea not associated with childbirth

Prolonged suckling.
Drugs (INH, phenothiazines, reserpine derivatives, amphetamines, spironolactone and tricyclic antidepressants).
Major stressors (surgery, trauma).
Hypothyroidism.
Pituitary tumors.

GALLBLADDER SONOGRAPHIC NON-VISUALIZATION[74]

ICD-10CM #	
	Varies with specific diagnosis

CAUSES OF SONOGRAPHIC NON-VISUALIZATION OF GALLBLADDER

Previous cholecystectomy.
Physiologic contraction.
Fibrosed gallbladder duct—chronic cholecystitis.
Air-filled gallbladder or emphysematous cholecystitis.
Tumefactive sludge.
Agenesis of gallbladder.
Ectopic location.

GALLBLADDER WALL THICKENING[74]

ICD-10CM #	
	Varies with specific diagnosis

CAUSES OF GALLBLADDER WALL THICKENING

Generalized Edematous States

Congestive heart failure.
Renal failure.
End-stage cirrhosis.
Hypoalbuminemia.

Inflammatory Conditions

Primary:
- Acute cholecystitis.
- Cholangitis.

Chronic cholecystitis.
Secondary:
Acute hepatitis.
Perforated duodenal ulcer.
Pancreatitis.
Diverticulitis/colitis.
Neoplastic Conditions
Gallbladder adenocarcinoma.
Metastases.
Miscellaneous
Adenomyomatosis.
Mural varicosities.

GALLSTONE DISEASE, PEDIATRIC PATIENT[19]

ICD-10CM # K80.20 Calculus of gallbladder without cholecystitis without obstruction

Biliary tract anomaly (e.g., choledochal cyst).
Cephalosporin use.
Crohn disease.
Cystic fibrosis.
Genetic predisposition (e.g., ABCB4, UGT1A1 mutations).
Hemolytic disorders (e.g., sickle-cell anemia, hereditary spherocytosis).
Hispanic or Latino ancestry.
Malabsorption.
Metabolic syndrome.
Obesity.
Parasitic disease (*Ascaris lumbricoides*).
Pregnancy.
Rapid weight loss.
Solid organ and hematologic transplant (e.g., liver, kidney, heart, bone marrow).
Total parenteral nutrition.

GASTRIC DILATATION[36]

ICD-10CM # K31.0 Acute dilatation of stomach

CAUSES OF A MASSIVELY DILATED STOMACH

Mechanical Gastric Outlet Obstruction
Duodenal or pyloric canal ulceration.
Carcinoma of pyloric antrum.
Extrinsic compression.
Paralytic Ileus
Surgery.
Trauma.
Peritonitis.
Pancreatitis.
Cholecystitis.
Diabetes mellitus.
Hepatic coma.
Drugs.
Gastric Volvulus
Intubation.
Air swallowing.

GASTRIC EMPTYING, DELAYED[3]

ICD-10CM # K30 Functional dyspepsia

CAUSES OF DELAYED GASTRIC EMPTYING

Mechanical Causes
Peptic ulcer disease, scarred pylorus.
Malignancy: gastric cancer, gastric lymphoma, pancreatic cancer.
Gastric surgery: vagotomy, gastric resection, Roux-en-Y anastomosis.
Crohn disease.
Endocrine and Metabolic Causes
Diabetes mellitus.
Hypothyroidism.
Hypoadrenal states.
Electrolyte abnormalities.
Chronic renal failure.
Medications.
Anticholinergics.
Opiates.
Dopamine agonists.
Tricyclic antidepressants.
Abnormalities of Gastric Smooth Muscle
Scleroderma.
Polymyositis, dermatomyositis.
Amyloidosis.
Pseudoobstruction.
Myotonic dystrophy.
Neuropathy.
Scleroderma.
Amyloidosis.
Autonomic neuropathy.
Central Nervous System or Psychiatric Disorders
Brain stem tumors.
Spinal cord injury.
Anorexia nervosa.
Stress.
Miscellaneous
Idiopathic gastroparesis.
Gastroesophageal reflux disease.
Nonulcer (functional) dyspepsia.
Cancer cachexia or anorexia.

GASTRIC EMPTYING, RAPID

ICD-10CM # K30 Functional dyspepsia

Pancreatic insufficiency.
Dumping syndrome.
Peptic ulcer.
Celiac disease.
Promotility agents.
Zollinger-Ellison disease.

GASTROINTESTINAL BLEEDING, PEDIATRIC PATIENT[54]

ICD-10CM # K92.2 Gastrointestinal hemorrhage, unspecified

INFANT

Common
Bacterial enteritis.
Milk protein allergy intolerance.
Intussusception.
Swallowed maternal blood.
Anal fissure.
Lymphonodular hyperplasia
Rare
Volvulus.
Necrotizing enterocolitis.
Meckel diverticulum.
Stress ulcer, gastritis.
Coagulation disorder (hemorrhagic disease of newborn).
Esophagitis.

CHILD

Common
Bacterial enteritis.
Anal fissure.
Colonic polyps.
Intussusception.
Peptic ulcer/gastritis.
Swallowed epistaxis.
Prolapse (traumatic) gastropathy secondary to emesis.
Mallory-Weiss syndrome.
Rare
Esophageal varices.
Esophagitis.
Meckel diverticulum.
Lymphonodular hyperplasia.
Henoch-Schönlein purpura.
Foreign body.
Hemangioma, arteriovenous malformation.
Sexual abuse.
Hemolytic-uremic syndrome.
Inflammatory bowel disease.
Coagulopathy.
Duplication cyst:
Angiodysplasia.
Angiodysplasia with von Willebrand disease.
Blue rubber bleb nevus syndrome.

ADOLESCENT

Common
Bacterial enteritis.
Inflammatory bowel disease.
Peptic ulcer/gastritis.
Prolapse (traumatic) gastropathy secondary to emesis.
Mallory-Weiss syndrome.
Colonic polyps.
Anal fissure.
Rare
Hemorrhoids.
Esophageal varices.
Esophagitis.
Pill ulcer.
Telangiectasia-angiodysplasia.
Graft versus host disease.
Duplication cyst:
Angiodysplasia.
Angiodysplasia with von Willebrand disease.
Blue rubber bleb nevus syndrome.

GASTROINTESTINAL OBSTRUCTION, PEDIATRIC PATIENT[54]

ICD-10CM #		
	K56.2	Volvulus
	K5.1	Intussusception
	K56.9	Ileus unspecified
	K56.6	Other and unspecified intestinal obstruction

Esophagus

Congenital

Esophageal atresia.
Vascular rings.
Schatzki ring.
Tracheobronchial remnant.

Acquired

Esophageal stricture.
Foreign body.
Achalasia.
Chagas disease.
Collagen vascular disease.

Stomach

Congenital

Antral webs.
Pyloric stenosis.

Acquired

Bezoar, foreign body.
Pyloric stricture (ulcer).
Chronic granulomatous disease of childhood.
Eosinophilic gastroenteritis.
Crohn disease.
Epidermolysis bullosa.

Small Intestine

Congenital

Duodenal atresia.
Annular pancreas.
Malrotation/volvulus.
Malrotation/Ladd bands.
Ileal atresia.
Meconium ileus.
Meckel diverticulum with volvulus or intussusception.
Inguinal hernia.
Internal hernia.
Intestinal duplication.
Pseudoobstruction.

Acquired

Postsurgical adhesions.
Crohn disease.
Intussusception.
Distal ileal obstruction syndrome (cystic fibrosis).
Duodenal hematoma.
Superior mesenteric artery syndrome.

Colon

Congenital

Meconium plug.
Hirschsprung disease.
Colonic atresia, stenosis.
Imperforate anus.
Rectal stenosis.
Pseudoobstruction.
Volvulus.
Colonic duplication.

Acquired

Ulcerative colitis (toxic megacolon).
Chagas disease.
Crohn disease.
Fibrosing colonopathy (cystic fibrosis).

GASTROINTESTINAL SYMPTOMS IN CHILDREN, NONDIGESTIVE CAUSES[54]

ICD-10CM #	Varies with specific diagnosis

Anorexia

Systemic disease: inflammatory, neoplastic.
Cardiorespiratory compromise.
Iatrogenic: drug therapy, unpalatable therapeutic diets.
Depression.
Anorexia nervosa.

Vomiting

Inborn errors of metabolism.
Medications: erythromycin, chemotherapy, nonsteroidal antiinflammatory drugs, marijuana.
Increased intracranial pressure.
Brain tumor.
Infection of the urinary tract.
Labyrinthitis.
Adrenal insufficiency.
Pregnancy.
Psychogenic.
Abdominal migraine.
Poisoning/toxins.
Renal disease.

Diarrhea

Infection: otitis media, urinary tract infection.
Uremia.
Medications: antibiotics, cisapride.
Tumors: neuroblastoma.
Pericarditis.
Adrenal insufficiency.

Constipation

Hypothyroidism.
Spina bifida.
Developmental delay.
Dehydration: diabetes insipidus, renal tubular lesions.
Medications: narcotics.
Lead poisoning.
Infant botulism.

Abdominal Pain

Pyelonephritis, hydronephrosis, renal colic.
Pneumonia (lower lobe).
Pelvic inflammatory disease.
Porphyria.
Fabry disease.
Angioedema.
Endocarditis.
Abdominal migraine.
Familial Mediterranean fever.
Sexual or physical abuse.
Systemic lupus erythematosus.
School phobia.
Sickle cell crisis.
Vertebral disk inflammation.
Psoas abscess.
Pelvic osteomyelitis or myositis.
Medications.

Abdominal Distention Or Mass

Ascites: nephrotic syndrome, neoplasm, heart failure.
Discrete mass: Wilms tumor, hydronephrosis, neuroblastoma, mesenteric cyst, hepatoblastoma, lymphoma.
Pregnancy.

Jaundice

Hemolytic disease.
Urinary tract infection.
Sepsis.
Hypothyroidism.
Panhypopituitarism.

GENITAL DISCHARGE, FEMALE[24]

ICD-10CM #	N94.9	Unspecified condition associated with female genital organs and menstrual cycle

Physiologic discharge: cervical mucus, vaginal transudation, bacteria, squamous epithelial cells.
Individual variation.
Pregnancy.
Sexual response.
Menstrual cycle variation.
Infection.
Foreign body: tampon, cervical cap, other.
Neoplasm.
Fistula.
IUD.
Cervical ectropion.
Spermicide.
Nongenital causes: urinary incontinence, urinary tract fistula, Crohn disease, rectovaginal fistula.

GENITAL LESIONS, INFECTIOUS CAUSES[10]

ICD-10CM #	Varies with specific diagnosis

INFECTIOUS CAUSES OF GENITAL LESIONS

Sexually Transmitted Infections

Syphilis:
  Primary (chancre).
  Secondary (condyloma latum).
Herpes simplex virus types 1 and 2.
Chancroid *(Haemophilus ducreyi).*
Lymphogranuloma venereum.
Granuloma inguinale (donovanosis).
Human papillomavirus.
Sarcoptes scabiei.
Molluscum contagiosum.

Nonsexually Transmitted Infections

Folliculitis.
Tuberculosis.
Tularemia.
Histoplasmosis.
Candida (balanitis or vaginitis).
Amebiasis.

GENITAL LESIONS, NONINFECTIOUS CAUSES[10]

ICD-10CM #	Varies with specific diagnosis

NONVENEREAL CAUSES OF GENITAL LESIONS

Trauma.
Malignancies (e.g., squamous cell carcinoma).
Behçet syndrome.
Lipschütz vulvar ulcers.
Peyronie disease.
Fixed-drug eruption.
Eczema.
Psoriasis.
Inflammatory bowel disease.
Contact dermatitis.

Lichen planus.
Hidradenitis suppurativa.
Postinflammatory hypopigmentation.
Aphthous ulcers (associated with human immunodeficiency virus).

GENITAL SORES[3]

ICD-10CM #		
	A60.9	Anogenital herpesviral infection, unspecified
	A51.0	Primary genital syphilis
	A63.0	Anogenital (venereal) warts
	A57	Chancroid
	A58	Granuloma inguinale
	A55	Chlamydial lymphogranuloma (venereum)
	N94.89	Other specified conditions associated with female genital organs and menstrual cycle
	N50.8	Other specified disorders of male genital organs

Herpes genitalis.
Syphilis.
Chancroid.
Lymphogranuloma venereum.
Granuloma inguinale.
Condyloma acuminatum.
Neoplastic lesion.
Trauma.

GLOMERULONEPHRITIS ASSOCIATED WITH MALIGNANCY[79]

ICD-10CM #		
	N00.9	Acute nephritic syndrome with unspecified morphologic changes

Membranous glomerulonephritis:
Breast cancer.
Lung cancer.
Colon cancer.
Prostate cancer.
Graft-versus-host disease.
Minimal change disease:
Hodgkin lymphoma.
Non-Hodgkin lymphoma.
Graft-versus-host disease.
Case reports.
Immunoglobulin A nephritis.
Antineutrophil cytoplasmic antibody vasculitis.
Focal segmental glomerulosclerosis.

GLOMERULONEPHRITIS, RAPIDLY PROGRESSIVE[3]

ICD-10CM #		
	N05.9	Unspecified nephritic syndrome with unspecified morphologic changes

DIFFERENTIAL DIAGNOSIS OF RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS

Linear Immune Staining
Anti-GBM disease.
Goodpasture syndrome.
Rarely membranous glomerulonephritis.

Granular Immune Staining
Subacute bacterial endocarditis (past infectious).
Lupus nephritis.
Cryoglobulinemia.
Membranoproliferative glomerulonephritis (type II more than type I).
Immunoglobulin A nephropathy, Henoch-Schönlein purpura.
Idiopathic.

No Immune Staining (Pauci-immune)
Antineutrophil cytoplasmic antibody-associated vasculitis (Wegener granulomatosis, microscopic polyangiitis, Churg-Strauss syndrome).
Idiopathic.

GLOMERULOPATHIES, THROMBOTIC, MICROANGIOPATHIC[3]

ICD-10CM #		
	M31.1	Thrombotic microangiopathy

THROMBOTIC MICROANGIOPATHIC GLOMERULOPATHIES

Thrombotic thrombocytopenic purpura.
Hemolytic-uremic syndrome.
Malignant hypertension.
Scleroderma renal crisis.
Preeclampsia, eclampsia.
HELLP syndrome (hemolysis, elevated liver enzymes, low platelets).
Antiphospholipid antibody syndrome.
Drugs: oral contraceptives, quinine, cyclosporine, tacrolimus, ticlopidine, clopidogrel.

GLOMERULOSCLEROSIS, FOCAL SEGMENTAL[3]

ICD-10CM #		
	N03.3	Chronic nephritic syndrome with diffuse mesangial proliferative glomerulonephritis

ETIOLOGY OF FOCAL SEGMENTAL GLOMERULOSCLEROSIS (FSGS)

Primary idiopathic FSGS.
Secondary FSGS.
HIV (usually collapsing variant).
Reflux nephropathy.
Heroin abuse.
Sickle cell disease.
Oligomeganephronia.
Renal dysgenesis or agenesis (low nephron mass).
Radiation nephritis.
Familial podocytopathies.
NPHS1 (nephrin) mutation.
NPHS2 (podocin) mutation.
TRPC6 (cation channel) mutation.
ACTN4 (a-actinin 4 mutation).

GLOSSODYNIA[86]

ICD-10CM #		
	K14.6	Glossodynia

DENTURE-RELATED

Dentures (ill-fitting, monomer from denture base).
Dental plaque.
Oral parafunction.

INFECTIVE/DERMATOLOGIC

Candidiasis.
Lichen planus.

DEFICIENCY STATES

Iron, B_{12}, folate, B_2 (riboflavin), B_6 (pyridoxine), zinc.

ENDOCRINE

Diabetes.
Myxedema.
Hormonal changes occurring during menopause.

NEUROLOGICALLY MEDIATED

Referred from tonsils, teeth.
Lingual nerve neuropathy.
Glossopharyngeal neuralgia.
Esophageal reflux.

IATROGENIC

Mouthwash.

XEROSTOMIA
PSYCHOGENIC
IDIOPATHIC

GLUCOCORTICOID DEFICIENCY[32]

ICD-10CM #		
	E27.1	Primary adrenocortical insufficiency
	E27.3	Drug-induced adrenocortical insufficiency

ACTH-independent causes.
TB.
Autoimmune (idiopathic).
Other rare causes:
- Fungal infection.
- Adrenal hemorrhage.
- Metastases.
- Sarcoidosis.
- Amyloidosis.
- Adrenoleukodystrophy.
- Adrenomyeloneuropathy.
- HIV infection.
- Congenital adrenal hyperplasia.
- Medications (e.g., ketoconazole).

ACTH-dependent causes:
- Hypothalamic-pituitary-adrenal suppression.
- Exogenous.
- Glucocorticoid.
- ACTH.
- Endogenous—cure of Cushing syndrome.

Hypothalamic-pituitary lesions.
- Neoplasm:
  - Primary pituitary tumor.
  - Metastatic tumor.
  - Craniopharyngioma.

Infection:
- Tuberculosis.
- Actinomycosis.
- Nocardiosis.

Sarcoid.
Head trauma.
Isolated ACTH deficiency.

GOITER

ICD-10CM #		
	E01.2	Iodine-deficiency related (endemic) goiter, unspecified
	E04.9	Nontoxic goiter, unspecified
	E04.9	Nontoxic goiter, unspecified
	E07.1	Dyshormogenetic goiter
	E01.2	Iodine-deficiency related (endemic) goiter, unspecified
	E04.9	Nontoxic goiter, unspecified
	E04.2	Nontoxic multinodular goiter
	E04.0	Nontoxic diffuse goiter
	E05.10	Thyrotoxicosis with toxic single thyroid nodule without thyrotoxic crisis or storm

Thyroiditis.
Toxic multinodular goiter.
Graves disease.
Medications (PTU, methimazole, sulfonamides, sulfonylureas, ethionamide, amiodarone, lithium, etc.).
Iodine deficiency.
Sarcoidosis, amyloidosis.
Defective thyroid hormone synthesis.
Resistance to thyroid hormone.

GRANULOMATOUS DERMATITIDES

ICD-10CM #		
	L92.9	Granulomatous disorder of the skin and subcutaneous tissue, unspecified

Granuloma annulare.
Sarcoidosis.
Necrobiosis lipoidica diabeticorum.
Cutaneous Crohn disease.
Rheumatoid nodules.
Annular elastolytic giant cell granuloma (actinic granuloma).
Foreign body granuloma.

GRANULOMATOUS DISORDERS[75]

ICD-10CM #		
	M31.30	Granulomatosis with polyangiitis without renal involvement
	K75.3	Granulomatous hepatitis
	L92.9	Granulomatous disorder of skin and subcutaneous tissue, unspecified

INFECTIONS

Fungi
Histoplasma.
Coccidioides.
Blastomyces.
Sporothrix.
Aspergillus.
Cryptococcus.
Protozoa
Toxoplasma.
Leishmania.
Metazoa
Toxocara.
Schistosoma.
Spirochetes
Treponema pallidum.
T. pertenue.
T. carateum.
Mycobacteria
M. tuberculosis.
M. leprae.
M. kansasii.
M. marinum.
M. avian.
Bacille Calmette-Guérin (BCG) vaccine.
Bacteria
Brucella.
Yersinia.
Other Infections
Cat-scratch disease.
Lymphogranuloma.

NEOPLASIA

Carcinoma.
Reticulosis.
Pinealoma.
Dysgerminoma.
Seminoma.
Reticulum cell sarcoma.
Malignant nasal granuloma.

CHEMICALS

Beryllium.
Zirconium.
Silica.
Starch.

IMMUNOLOGIC ABERRATIONS

Sarcoidosis.
Crohn disease.
Primary biliary cirrhosis.
Granulomatosis with polyangiitis.
Giant cell arteritis.
Peyronie disease.
Hypogammaglobulinemia.
SLE.
Lymphomatoid granulomatosis.
Histiocytosis X.
Hepatic granulomatous disease.
Immune complex disease.
Rosenthal-Melkersson syndrome.
Churg-Strauss allergic granulomatosis.

LEUKOCYTE OXIDASE DEFECT

Chronic granulomatous disease of childhood.

EXTRINSIC ALLERGIC ALVEOLITIS

Farmer's lung.
Bird fancier's.
Mushroom worker's.
Suberosis (cork dust).
Bagassosis.
Maple bark stripper's.
Paprika splitter's.
Coffee bean.
Spatlese lung.

OTHER DISORDERS

Whipple disease.
Pyrexia of unknown origin.
Radiotherapy.
Cancer chemotherapy.
Panniculitis.
Chalazion.
Sebaceous cyst.
Dermoid.
Sea urchin spine injury.

GRANULOMATOUS LIVER DISEASE

ICD-10CM #		
	K75.3	Granulomatous hepatitis

Sarcoidosis.
Granulomatosis with polyangiitis.
Vasculitis.
Inflammatory bowel disease.
Allergic granulomatosis.
Erythema nodosum.
Infections (fungal, viral, parasitic).
Primary biliary cirrhosis.
Lymphoma.
Hodgkin disease.
Drugs (e.g., allopurinol, hydralazine, sulfonamides, penicillins).
Toxins (copper sulfate, beryllium).

GREEN OR BLUE URINE

ICD-10CM #		
	R82	Other abnormal findings in urine

Pseudomonal urinary tract infection
Medications: triamterene, amitriptyline, IV cimetidine, IV promethazine.
Biliverdin.
Dyes (methylene blue, indigo carmine).

GROIN LUMP[86]

ICD-10CM #		
	R19.09	Other intraabdominal and pelvic swelling, mass and lump
	R22.9	Localized swelling, mass and lump, unspecified

COMMON CAUSES

Inguinal hernia.
Femoral hernia.
Lymph node.

OTHER CAUSES

Saphena varix.
Femoral artery aneurysm/pseudoaneurysm.
Psoas abscess.
Lipoma of the cord.
Encysted hydrocele of the cord (male).
Testicular maldescent (male).
Hydrocele of canal of Nuck (female).

GROIN MASSES

ICD-10CM #		
	R22.9	Localized swelling, mass and lump, unspecified
	S39.848A	Other specified injuries of external genitals, initial encounter

Hernia (inguinal, femoral).
Hydrocele.
Varicocele.
Sebaceous cyst.
Hidradenitis of inguinal apocrine glands.
Neoplasm: lymphoma, metastases.
Lipoma.
Hematoma.
Reactive inguinal adenopathy, femoral adenitis.
Folliculitis, psoas abscess.
Epididymitis, testicular torsion, ectopic testes.
Aneurysm or pseudoaneurysm of femoral artery.

GROIN PAIN[15]

ICD-10CM #		
	R52	Pain, unspecified

DIFFERENTIAL DIAGNOSIS OF GROIN PAIN

Surgery
Workers' Compensation.
Hernia.
Recurrent hernia.
Posthernia.
Orthopedic
Hip disorders:
- Acetabular labral tears.
- Avascular necrosis.
- Chondritis dissecans.
- Legg-Calvé-Perthes disease.
- Osteoarthritis.
- Pelvic stress fractures.
- Slipped femoral capital epiphysis.
- Synovitis.

Urology
Cystitis.
Epididymitis.
Nephrolithiasis.
Prostate cancer.
Prostatitis.
Torsion of testes.
Urethral extravasation.
Urinary tract infection.
Vas granuloma/fibrosis.
Dermatology
Lymphadenitis.
Psoriasis/burn.
Sebaceous cyst/hidradenitis.
Thrombophlebitis/cellulitis.
Neurosurgery
Disk disease.
Spinal injuries, inflammation, tumors.
Spondylolisthesis.
Spondylolysis.
Rheumatology
Connective tissue disorders.
Iliopsoas bursitis.
Osteitis pubis.
Systemic lupus erythematosus.
Neurology
Lumbosacral disorders.
Neurofibromatosis.
Infectious Disease
Herpes zoster.
HIV/tuberculosis.
Lyme disease.
Psoas abscess.
Sports Medicine
"Sports hernia" (adductor strains).
Gilmore groin.
Vascular
Abscess hematoma.
Post-vein stripping.
Pseudoaneurysm.
Vascular graft.
Gastroenterology
Appendicitis/adhesions.
Diverticulitis.
Inflammatory retroperitoneal phlegmon (pancreatitis).
Meckel diverticulum.
Granulomatous colitis.
Gynecology
Cesarean section.
Cervical cancer.
Endometriosis.
Tubal/ovarian disorders.

GROIN PAIN, ACTIVE PATIENT[85]

ICD-10CM #		
	S39.848A	Other specified injuries of external genitals, initial encounter
	R52	Pain, unspecified

MUSCULOSKELETAL

Avascular necrosis of the femoral head.
Avulsion fracture (lesser trochanter, anterior superior iliac spine, anterior inferior iliac spine).
Bursitis (iliopectineal, trochanteric).
Entrapment of the ilioinguinal or iliofemoral nerve.
Gracilis syndrome.
Muscle tear (adductors, iliopsoas, rectus abdominis, gracilis, sartorius, rectus femoris).
Myositis ossificans of the hip muscles.
Osteitis pubis.
Osteoarthritis of the femoral head.
Slipped capital femoral epiphysis.
Stress fracture of the femoral head or neck and pubis.
Synovitis.

HERNIA-RELATED

Avulsion of the internal oblique muscle in the conjoined tendon.
Defect at the insertion of the rectus abdominis muscle.
Direct inguinal hernia.
Femoral ring hernia.
Indirect inguinal hernia.
Inguinal canal weakness.

UROLOGIC

Epididymitis.
Fracture of the testis.
Hydrocele.
Kidney stone.
Posterior urethritis.
Prostatitis.
Testicular cancer.
Torsion of the testis.
Urinary tract infection.
Varicocele.

GYNECOLOGIC

Ectopic pregnancy.
Ovarian cyst.
Pelvic inflammatory disease.
Torsion of the ovary.
Vaginitis.

LYMPHATIC ENLARGEMENT IN GROIN

GYNECOMASTIA

ICD-10CM #		
	N62	Hypertrophy of breast

Physiologic (puberty, newborns, aging).
Drugs (estrogen and estrogen precursors, 5-a reductase inhibitors, digitalis, testosterone and exogenous androgens, clomiphene, cimetidine, spironolactone, ketoconazole, amiodarone, ACE inhibitors, isoniazid, phenytoin, methyldopa, metoclopramide, phenothiazine).
Increased prolactin level (prolactinoma).
Liver disease.
Adrenal disease.
Thyrotoxicosis.
Increased estrogen production (hCG-producing tumor, testicular tumor, bronchogenic carcinoma).
Secondary hypogonadism.
Primary gonadal failure (trauma, castration, viral orchitis, granulomatous disease).
Defects in androgen synthesis.
Testosterone deficiency.
Klinefelter syndrome.

HAIR LOSS[38]

ICD-10CM #		
	L63.8	Other alopecia areata
	L63.9	Alopecia areata, unspecified
	L64.0	Drug-induced androgenic alopecia
	L64.8	Other androgenic alopecia

GENERALIZED

Acute blood loss.*
Childbirth.
Crash diets (inadequate protein).
Drugs:
- Coumarin.
- Heparin.
- Propranolol.
- Vitamin A.
- High fever.

Hypothyroidism and hyperthyroidisms.

*Diffuse, uniform loss, but many hairs left randomly distributed in area of loss.

GROIN MASSES

ICD-10CM #

	L63.9	Alopecia areata, unspecified
	L64.0	Drug-induced androgenic alopecia
	L64.8	Other androgenic alopecia

GENERALIZED

Acute blood loss.*
Childbirth.
Crash diets (inadequate protein).
Drugs:
- Coumarin.
- Heparin.
- Propranolol.
- Vitamin A.
- High fever.

Hypothyroidism and hyperthyroidisms.

*Diffuse, uniform loss, but many hairs left randomly distributed in area of loss.

Physical stress (e.g., surgery).
Physiologic stress (e.g., neonate).
Psychologic stress.
Severe illness (e.g., systemic lupus erythematosis).
Cancer chemotherapeutic agents.
Poisoning:
  Thallium (rat poison).
  Arsenic.
Radiation therapy.
Secondary syphilis: "moth eaten" alopecia.

LOCALIZED

Androgenetic alopecia:†
  Male pattern.
  Female pattern.
Hirsutism.
Alopecia areata.
Trichotillomania.
Traction alopecia.
Scarring alopecia:
  Developmental defects: aplasia cutis.
Physical injury: burns, pressure.
Infection:
  Fungal: kerion.
  Bacterial: folliculitis, furuncle.
  Viral: herpes zoster.
Neoplasms:
  Metastatic carcinoma.
  Sclerosing basal cell carcinoma.
Lupus erythematosus.
Lichen planus.
Cicatricial pemphigoid.
Scleroderma.

HALITOSIS

ICD-10CM # R19.6 Halitosis

Tobacco use.
Alcohol use.
Dry mouth (mouth breathing, inadequate fluid intake).
Foods (onion, garlic, meats, nuts, protein drinks).
Disease of mouth or nose (infections, cancer, inflammation).
Medications (antihistamines, antidepressants).
Systemic disorders (diabetes, uremia).
GI disorders (esophageal diverticula, hiatal hernia, GERD, achalasia).
Sinusitis.
Pulmonary disorders (bronchiectasis, pneumonia, neoplasms, TB).

HALLUCINATIONS, VISUAL, NEUROLOGIC CAUSES[51]

ICD-10CM # R44.1 Visual hallucinations

Blindness/sensory deprivation—Charles Bonnet syndrome.
Palinopsia.
Dementia-producing diseases:
  Alzheimer.
  Dementia with Lewy bodies.*
  Parkinson.†
Intoxications:
  Alcoholic hallucinosis.
    Delirium tremens (DTs).
Hallucinogens:
  Amphetamines.
  Cocaine.
  Lysergic acid diethylamide (LSD).
  Phencyclidine (PCP).
Medicines:
  Atropine, scopolamine.
  Levodopa and dopamine agonists.
  Steroids.
Migraine with aura (classic migraine).
Narcolepsy: hypnopompic (awakening) and hypnagogic (falling asleep) hallucinations.
Seizures.
Peduncular hallucinations.

HAND PAIN AND SWELLING[16]

ICD-10CM # 729.5 Pain in limb

Trauma.
Gout.
Pseudogout.
Cellulitis.
Lymphangitis.
DVT of upper extremity.
Thrombophlebitis.
RA.
Remitting seronegative symmetrical synovitis with pitting edema (RS3PE).
Polymyalgia rheumatica.
Mixed connective tissue disease.
Scleroderma.
Rupture of the olecranon bursa.
Metzger syndrome (neoplasia).
The puffy hand of drug addiction.
Reflex sympathetic dystrophy.
Eosinophilic fasciitis.
Sickle cell (hand-foot syndrome).
Leprosy.
Factitial (the rubber band syndrome).

HEADACHE[31]

ICD-10CM #	G44.1	Vascular headache, not elsewhere classified
	R51	Headache
	G44.209	Tension-type headache, unspecified, not intractable
	G44.009	Cluster headache syndrome, unspecified, not intractable
	G43.909	Migraine, unspecified, not intractable, without status migrainosus
	G44.1	Vascular headache, not elsewhere classified

Vascular: migraine, cluster headaches, temporal arteritis, hypertension, cavernous sinus thrombosis.
Musculoskeletal: neck and shoulder muscle contraction, strain of extraocular and/or intraocular muscles, cervical spondylosis, temporomandibular arthritis.
Infections: meningitis, encephalitis, brain abscess, sepsis, sinusitis, osteomyelitis, parotitis, mastoiditis.
Cerebral neoplasm.
Subdural hematoma.
Cerebral hemorrhage/infarct.
Pseudotumor cerebri.
Normal-pressure hydrocephalus (NPH).
Postlumbar puncture.
Cerebral aneurysm, arteriovenous malformations.
Posttrauma.
Dental problems: abscess, periodontitis, poorly fitting dentures.
Trigeminal neuralgia, glossopharyngeal neuralgia.
Otitis and other ear diseases.
Glaucoma and other eye diseases.
Metabolic: uremia, carbon monoxide inhalation, hypoxia.
Pheochromocytoma, hypoglycemia, hypothyroidism.
Effort induced: benign exertional headache, cough, headache, coital cephalalgia.
Drugs: alcohol, nitrates, histamine antagonists.
Paget disease of the skull.
Emotional, psychiatric.

HEADACHE, ACUTE[23]

ICD-10CM # R51 Headache

DIFFERENTIAL DIAGNOSIS OF ACUTE HEADACHE

Evaluation of the first acute headache should exclude pathologic causes listed here before consideration of more common etiologies.
Increased intracranial pressure (ICP): trauma, hemorrhage, tumor, hydrocephalus, pseudotumor cerebri, abscess, arachnoid cyst, cerebral edema.
Decreased ICP: after ventriculoperitoneal shunt, lumbar puncture, cerebrospinal fluid leak from basilar skull fracture.
Meningeal inflammation: meningitis, leukemia, subarachnoid or subdural hemorrhage.
Vascular: Vasculitis, arteriovenous malformation, hypertension, cerebrovascular accident.
Bone, soft tissue: referred pain from scalp, eyes, ears, sinuses, nose, teeth, pharynx, cervical spine, temporomandibular joint.
Infection: systemic infection, encephalitis, sinusitis, etc.
First migraine.

HEADACHE AND FACIAL PAIN[82]

ICD-10CM #	R51	Headache
	G44.1	Vascular headache, not elsewhere classified

VASCULAR HEADACHES

Migraine

Migraine with headaches and inconspicuous neurologic features:
  Migraine without aura ("common migraine").

†Most or all hair missing from involved area.
*Although visual hallucinations are likely to complicate almost any form of dementia, they are characteristic of dementia with Lewy bodies disease.

†Dopaminergic medications such as levodopa-carbidopa (Sinemet) are more likely than Parkinson disease itself to produce hallucinations.

Migraine with headaches and conspicuous neurologic features:
With transient neurologic symptoms:
Migraine with typical aura ("classic migraine").
Sensory, basilar, and hemiplegic migraine.
With prolonged or permanent neurologic features ("complicated migraine"):
Ophthalmoplegic migraine.
Migrainous infarction.
Migraine without headaches but with conspicuous neurologic features ("migraine equivalents"):
Abdominal migraine.
Benign paroxysmal vertigo of childhood.
Migraine aura without headache ("isolated auras," transient migrainous accompaniments).

Cluster Headaches

Episodic cluster headache ("cyclic cluster headaches").
Chronic cluster headaches.
Chronic paroxysmal hemicrania.

Other Vascular Headaches

Headaches of reactive vasodilation (fever, drug-induced, postictal, hypoglycemia, hypoxia, hypercarbia, hyperthyroidism).
Headaches associated with arterial hypertension:
Chronic severe hypertension (diastolic 120 mm Hg).
Paroxysmal severe hypertension (pheochromocytoma, some coital headaches).
Headaches caused by cranial arteritis:
Giant cell arteritis ("temporal arteritis").
Other vasculitides.

HEADACHES ASSOCIATED WITH DEMONSTRABLE MUSCLE SPASM

Headache caused by posturally induced or perilesional muscle spasm:
Headaches of sustained or impaired posture (e.g., prolonged close work, driving).
Headaches associated with cervical spondylosis and other diseases of cervical spine.
Myofascial pain dysfunction syndrome (headache or facial pain associated with disorders of teeth, jaws, and related structures, or "TMJ syndrome").
Headaches caused by psychophysiologic muscular contraction ("muscle contraction headaches," or tension-type headache associated with disorder of pericranial muscles).

HEADACHES AND FACIAL PAIN WITHOUT DEMONSTRABLE PHYSICAL SUBSTRATE

Headaches of uncertain etiology:
"Tension headaches" (tension-type headache unassociated with disorder of pericranial muscles).
Some forms of posttraumatic headache.
Psychogenic headaches (e.g., hypochondriacal, conversional, delusional, malingered).
Facial pain of uncertain etiology ("atypical facial pain").

COMBINED TENSION-MIGRAINE HEADACHES

Episodic migraine superimposed on chronic tension headaches.
Chronic daily headaches:
Associated with analgesic and/or ergotamine overuse ("rebound headaches").
Not associated with drug overuse.

HEADACHES AND HEAD PAINS CAUSED BY DISEASES OF EYES, EARS, NOSE, SINUSES, TEETH, OR SKULL

Headaches Caused by Meningeal Inflammation

Subarachnoid hemorrhage.
Meningitis and meningoencephalitis.
Others (e.g., meningeal carcinomatosis).

HEADACHES ASSOCIATED WITH ALTERED INTRACRANIAL PRESSURE ("TRACTION HEADACHES")

Increased Intracranial Pressure

Intracranial mass lesions (neoplasm, hematoma, abscess, etc.).
Hydrocephalus.
Benign intracranial hypertension.
Venous sinus thrombosis.

Decreased Intracranial Pressure

Post-lumbar puncture headaches.
Spontaneous hypoliquorrheic headaches.

HEADACHES AND HEAD PAINS CAUSED BY CRANIAL NEURALGIAS

Presumed Irritation of Superficial Nerves

Occipital neuralgia.
Supraorbital neuralgia.

Presumed Irritation of Intracranial Nerves

Trigeminal neuralgia ("tic douloureux").
Glossopharyngeal neuralgia.

HEADACHE, CHRONIC[23]

ICD-10CM #		
	R51	Headache

DIFFERENTIAL DIAGNOSIS OF RECURRENT OR CHRONIC HEADACHES

Migraine (with or without aura).
Tension.
Analgesic rebound.
Caffeine withdrawal.
Sleep deprivation (e.g., in children with sleep apnea) or chronic hypoxia.
Tumor.
Psychogenic: conversion disorder, malingering.
Cluster headache.

HEAD AND NECK, SOFT TISSUE MASSES

ICD-10CM #		
	R22.0	Localized swelling, mass and lump, head
	R22.1	Localized swelling, mass and lump, neck

Lipoma.
Pilar cyst.
Epidermal inclusion cyst.
Dermoid cyst.
Bone cyst.
Hemangioma.
Eosinophilic granuloma.
Other: facial nerve neuroma, teratoma, rhabdomyoma, rhabdomyosarcoma, branchial cleft cyst.

HEARING LOSS, ACUTE[58]

ICD-10CM #		
	H91.23	Sudden idiopathic hearing loss, bilateral

Infectious: mumps, measles, influenza, herpes simplex, herpes zoster, CMV, mononucleosis, syphilis.
Vascular: macroglobulinemia, sickle cell disease, Berger disease, leukemia, polycythemia, fat emboli, hypercoagulable states.
Metabolic: diabetes, pregnancy, hyperlipoproteinemia.
Conductive: cerumen impaction, foreign bodies, otitis media, otitis externa, barotrauma, trauma.
Medications: aminoglycosides, loop diuretics, antineoplastics, salicylates, vancomycin.
Neoplasm: acoustic neuroma, metastatic neoplasm.

HEARTBURN AND INDIGESTION[76]

ICD-10CM #		
	R12	Heartburn
	K30	Functional dyspepsia

Reflux esophagitis.
Gastritis.
Nonulcer dyspepsia.
Functional GI disorder (anxiety disorder, social/environmental stresses).
Excessive intestinal gas (ingestion of flatulogenic foods, GI stasis, constipation).
Gas entrapment (hepatitis or splenic flexure syndrome).
Neoplasm (adenocarcinoma of stomach or esophagus, lymphoma).
Gallbladder disease.

HEART DISEASE, TRAUMATIC CAUSES[59]

ICD-10CM #		
	S26.020	Mild laceration of heart with hemopericardium
	S26.021	Moderate laceration of heart with hemopericardium
	S26.022	Major laceration of heart with hemopericardium

Penetrating:
Stab wounds: knives, swords, ice picks, fence posts, wire, sports.
Projectile wounds: handguns, rifles, nail guns, lawnmower projectiles.
Shotgun wounds: pellets, close-range versus distant.

Nonpenetrating (blunt):
- Motor vehicle accident:
  - Seat belt.
  - Air bag.
  - Dashboard/steering wheel.
- Vehicular-pedestrian accident.
- Falls from a height.
- Crushing: industrial accident.
- Blasts: improvised explosive devices, grenades, fragments (combined blunt/penetrating).
- Assault.
- Sternal or rib fractures.
- Recreational: sporting events (e.g., rodeo, baseball).

HEART FAILURE WITH PRESERVED LEFT VENTRICULAR EJECTION FRACTION[34]

ICD-10CM # I50.9 Heart failure, unspecified

CAUSES OF (AND ALTERNATIVE EXPLANATIONS FOR) HEART FAILURE WITH PRESERVED LEFT VENTRICULAR EJECTION FRACTION (>45% TO 50%)

Inaccurate diagnosis of heart failure (e.g., pulmonary disease, obesity).
Inaccurate measurements of ejection fraction.
Systolic function overestimated by ejection fraction (e.g., mitral regurgitation).
Episodic, unrecognized systolic dysfunction.
Intermittent ischemia.
Arrhythmia.
Severe hypertension.
Alcohol abuse.
Diastolic dysfunction.
Abnormalities of myocardial relaxation:
- Ischemia.
- Hypertrophy.

Abnormalities of myocardial compliance:
- Hypertrophy.
- Aging.
- Fibrosis.
- Diabetes mellitus.
- Infiltrative disease (amyloidosis, sarcoidosis).
- Storage disease (hemochromatosis).
- Endomyocardial disease (endomyocardial fibrosis, radiation, anthracyclines).

Pericardial disease (constriction, tamponade).

HEART FAILURE, ACUTE[7]

ICD-10CM # I50.9 Heart failure, unspecified

COMMON PRECIPITATING CAUSES OF ACUTE HF

Systemic hypertension.
Myocardial infarction or ischemia.
Dysrhythmia.
Systemic infection.
Anemia.
Dietary, physical, environmental, and emotional excesses.
Pregnancy.
Thyrotoxicosis or hypothyroidism.
Acute myocarditis.
Acute valvular dysfunction.
Pulmonary embolus.
Pharmacologic complications.

HEART FAILURE, CHRONIC[11]

ICD-10CM # I50.9 Heart failure, unspecified

Myocardial disease.
Coronary artery disease:
- Myocardial infarction.[19]
- Myocardial ischemia.

Chronic pressure overload:
- Hypertension.
- Obstructive valvular disease.

Chronic volume overload:
- Regurgitant valvular disease.
- Intracardiac (left-to-right) shunting.
- Extracardiac shunting.

Nonischemic dilated cardiomyopathy:
- Familial or genetic disorders.
- Infiltrative disorders.
- Toxic or drug-induced damage.
- Metabolic disorder.
- Viral or other infectious agents.

Disorders of rate and rhythm:
- Chronic bradyarrhythmias.
- Chronic tachyarrhythmias.
- Pulmonary heart disease
- Cor pulmonale.
- Pulmonary vascular disorders.

High-output states.
Metabolic disorders:
- Thyrotoxicosis.
- Nutritional disorders (beriberi).

Excessive blood flow requirements:
- Systemic arteriovenous shunting.
- Chronic anemia.

HEART FAILURE, CONGENITAL HEART DISEASE CAUSES[68]

ICD-10CM # I50.9 Heart failure, unspecified

CAUSES OF CONGESTIVE HEART FAILURE RESULTING FROM CONGENITAL HEART DISEASE

Age of Onset	Cause
At birth:	HLHS.
	Volume overload lesions:
	Severe tricuspid or pulmonary insufficiency.
	Large systemic arteriovenous fistula.
First week	TGA.
	PDA in small premature infants.
	HLHS (with more favorable anatomy).
	TAPVR, particularly those with pulmonary venous obstruction.
	Others.
	Systemic arteriovenous fistula.
	Critical AS or PS.
1-4 wk	COA with associated anomalies.
	Critical AS.
	Large left-to-right shunt lesions (VSD, PDA) in premature infants.
	All other lesions previously listed.
4-6 wk	Some left-to-right shunt lesions such as ECD.
6 wk-4 mo	Large VSD.
	Large PDA.
	Others, such as anomalous left coronary artery from the PA.

AS, Aortic stenosis; *COA,* coarctation of the aorta; *ECD,* endocardial cushion defect; *HLHS,* hypoplastic left heart syndrome; *PA,* pulmonary artery; *PDA,* patent ductus arteriosus; *PS,* pulmonary stenosis; *TAPVR,* total anomalous pulmonary venous return; *TGA,* transposition of the great arteries; *VSD,* ventricular septal defect.

[19] Indicates conditions that can also lead to HF with a preserved EF.

HEART FAILURE, PATHOGENIC CAUSES[34]

ICD-10CM # I50.9 Heart failure, unspecified

IMPAIRED SYSTOLIC (CONTRACTILE) FUNCTION

Ischemic damage or dysfunction:
- Myocardial infarction.
- Persistent or intermittent myocardial ischemia.
- Hypoperfusion (shock).

Chronic pressure overloading:
- Hypertension.
- Obstructive valvular disease.

Chronic volume overload:
- Regurgitant valvular disease.
- Intracardiac left-to-right shunting.
- Extracardiac shunting.

Nonischemic dilated cardiomyopathy:
- Familial/genetic disorders.
- Toxic/drug-induced damage
- Immunologically mediated necrosis.
- Infectious agents.
- Metabolic disorders.
- Infiltrative processes.
- Idiopathic conditions.

IMPAIRED DIASTOLIC FUNCTION (RESTRICTED FILLING, INCREASED STIFFNESS)

Pathologic myocardial hypertrophy:
- Primary (hypertrophic cardiomyopathies).
- Secondary (hypertension).
- Aging.
- Ischemic fibrosis.
- Restrictive cardiomyopathy:
  - Infiltrative disorders (amyloidosis, sarcoidosis).
  - Storage diseases (hemochromatosis, genetic abnormalities).

Endomyocardial disorders.

MECHANICAL ABNORMALITIES

Intracardiac:
- Obstructive valvular disease.
- Regurgitant valvular disease.
- Intracardiac shunts.
- Other congenital abnormalities.

Extracardiac:
- Obstructive (coarctation, supravalvular aortic stenosis).
- Left-to-right shunting (patent ductus arteriosus).

DISORDERS OF RATE AND RHYTHM

Bradyarrhythmias (sinus node dysfunction, conduction abnormalities).
Tachyarrhythmias (ineffective rhythms, chronic tachycardia).

PULMONARY HEART DISEASE

Cor pulmonale.
Pulmonary vascular disorders.

HIGH-OUTPUT STATES

Metabolic disorders:
- Thyrotoxicosis.
- Nutritional disorders (beriberi).
- Excessive blood flow requirements:
  - Chronic anemia.
  - Systemic arteriovenous shunting.

HEART FAILURE, PREGNANCY

ICD-10CM # I50.9 Heart failure, unspecified

Congenital valvular heart disease exacerbated by pregnancy.
Peripartum cardiomyopathy.
Untreated thyrotoxicosis.
Hypothyroidism.
Pulmonary hypertension.
Myocardial infarction.

HEAT STROKE[1]

ICD-10CM # T67.0 Heatstroke and sunstroke

Sepsis.
Encephalitis.
Meningitis.
Brain abscess.
Malaria (cerebral falciparum).
Typhoid fever.
Tetanus.
Alcohol withdrawal syndrome.
Neuroleptic malignant syndrome.
Anticholinergic toxicity.
Salicylate toxicity.
Phencyclidine hydrochloride (PCP), cocaine, or amphetamine toxicity.
Status epilepticus.
Cerebral hemorrhage.
Diabetic ketoacidosis.
Thyroid storm.

HEEL PAIN

ICD-10CM # M25.50 Pain in unspecified joint

Achilles tendonitis/tendinopathy (insertional, noninsertional).
Retrocalcaneal bursitis (superficial, deep).
Plantar fasciopathy.
Neuropathy (tarsal tunnel, posterior tibial nerve [medial calcaneal branch], abductor digiti quinti).
Calcaneal stress fracture.
Puncture wound, foreign body.
Cellulitis.
Spondyloarthropathy.
Fat pad atrophy.
Soft tissue tumor.
S1 radiculopathy.
Paget disease of bone.
Haglund deformity.
Primary or metastatic bone tumor.

HEEL PAIN, PLANTAR[50]

ICD-10CM # M79.609 Pain in unspecified limb

SKIN

Keratoses.
Verruca.
Ulcer.
Fissure.

CONNECTIVE TISSUE

Fat
Atrophy.
Panniculitis.
Dense Connective Tissue
Inflammatory fasciitis.
Fibromatosis.
Enthesopathy.
Bursitis.
Bone (Calcaneus)
Stress fracture.
Paget disease.
Benign bone cyst/tumor.
Malignant bone tumor.
Metabolic bone disease (osteopenia).
Nerve
Tarsal tunnel.
Plantar nerve entrapment.
S1 nerve root radiculopathy.
Painful peripheral neuropathy.

INFECTION

Dermatomycoses.
Acute osteomyelitis.
Plantar abscess.

MISCELLANEOUS

Foreign body.
Nonunion calcaneus fracture.
Psychogenic.
Idiopathic.

HEMARTHROSIS

ICD-10CM # T14.90 Injury, unspecified

Trauma.
Anticoagulant therapy.
Thrombocytopenia, thrombocytosis.
Bleeding disorders (e.g., von Willebrand disease).
Charcot joint.
Idiopathic.
Other: pigmented villonodular synovitis, hemangioma, synovioma, AV fistula, ruptured aneurysm.

HEMATEMESIS[86]

ICD-10CM # K92.0 Hematemesis

CAUSES OF HEMATEMESIS

Very Common
Gastric or duodenal ulcer or erosions.
Common
Mallory-Weiss tear (a laceration at the gastroesophageal junction).
Ulcerative esophagitis.
Esophageal varices.
Uncommon
Vascular malformations.
Ulcerated GI stromal tumor.
Carcinoma of esophagus or stomach.
Aortoenteric fistula.

HEMATURIA

ICD-10CM # R31.9 Hematuria, unspecified

Use the mnemonic TICS:

T (Trauma): blow to kidney, insertion of Foley catheter or foreign body in urethra, prolonged and severe exercise, very rapid emptying of overdistended bladder. (Tumor): hypernephroma, Wilms tumor, papillary carcinoma of the bladder, prostatic and urethral neoplasms.(Toxins): turpentine, phenols, sulfonamides and other antibiotics, cyclophosphamide, NSAIDs.

I (Infections): glomerulonephritis, TB, cystitis, prostatitis, urethritis, *Schistosoma haematobium,* yellow fever, blackwater fever. (Inflammatory processes): Goodpasture syndrome, periarteritis, postirradiation.

C (Calculi): renal, ureteral, bladder, urethra. (Cysts): simple cysts, polycystic disease. (Congenital anomalies): hemangiomas, aneurysms, AVM.

S (Surgery): invasive procedures, prostatic resection, cystoscopy.(Sickle cell disease and other hematologic disturbances): hemophilia, thrombocytopenia, anticoagulants.(Somewhere else): bleeding genitals, factitious (drug addicts).

HEMATURIA, DIFFERENTIAL BASED ON AGE AND SEX

ICD-10CM # R31.9 Hematuria, unspecified

0 TO 20 YR

Acute urinary tract infections.
Acute glomerulonephritis.
Congenital urinary tract anomalies with obstruction.
Trauma to genitals.

20 TO 40 YR
Acute urinary tract infection.
Trauma to genitals.
Urolithiasis.
Bladder cancer.

40 TO 60 YR (WOMEN)
Acute urinary tract infection.
Bladder cancer.
Urolithiasis.

40 TO 60 YR (MEN)
Acute urinary tract infection.
Bladder cancer.
Urolithiasis.

60 YR AND OLDER (WOMEN)
Acute urinary tract infection.
Bladder cancer.
Vaginal trauma or irritation.
Urolithiasis.

60 YR AND OLDER (MEN)
Acute urinary tract infection.
Benign prostatic hyperplasia.
Bladder cancer.
Urolithiasis.
Trauma.

HEMATURIA, IN CHILDREN[7]
ICD-10CM # R31.9 Hematuria, unspecified

EXTRARENAL
Trauma.
Meatal stenosis or posterior urethral valves.
Exercise.
Menstruation or rectal bleeding.
Foreign bodies.
Cystitis, urethritis, or epididymitis.

INTRARENAL
Pyelonephritis.
Renal or bladder stones or tumors.
Poststreptococcal or idiopathic glomerulonephritis.
Acute interstitial nephritis.
Acute tubular necrosis.
Basement membrane glomerular disease.
Renal vein or arterial thrombosis.
Recurrent familial hematuria.
Polycystic kidney disease.

SYSTEMIC
Henoch-Schönlein purpura.
Systemic lupus erythematosus.
Hemolytic-uremic syndrome.
Infectious mononucleosis.
Sickle cell disease or other hemoglobinopathies.
Bacterial endocarditis or artificial cardiac valves.
Bleeding disorders, warfarin, or aspirin.
Medications such as amitriptyline or chlorpromazine, radiocontrast dyes.
Munchausen syndrome or factitious.

HEMIPARESIS/HEMIPLEGIA
ICD-10CM # G81.00 Flaccid hemiplegia affecting unspecified side
G81.10 Spastic hemiplegia affecting unspecified side

CVA.
Transient ischemic attack.
Cerebral neoplasm.
Multiple sclerosis or other demyelinating disorder.
CNS infection.
Migraine.
Hypoglycemia
Subdural hematoma.
Vasculitis.
Todd paralysis.
Epidural hematoma.
Metabolic (hyperosmolar state, electrolyte imbalance).
Psychiatric disorders.
Congenital disorders.
Leukodystrophies.

HEMOLYSIS AND HEMOGLOBINURIA
ICD-10CM # P55.8 Other hemolytic diseases of newborn
P55.9 Hemolytic disease of newborn, unspecified
R82.3 Hemoglobinuria

Erythrocyte trauma (prosthetic cardiac valves, marching and severe trauma, extensive burns).
Infections (malaria, *Bartonella, Clostridium welchii*).
Brown recluse spider bite.
Incompatible blood transfusions.
Hemolytic-uremic syndrome.
Thrombotic thrombocytopenic purpura (TTP).
Paroxysmal nocturnal hemoglobinuria (PNH).
Drugs (penicillins, quinidine, methyldopa, sulfonamides, nitrofurantoin).
Erythrocyte enzyme deficiencies (e.g., exposure to fava beans in patients with glucose-6-phosphate dehydrogenase deficiency).

HEMOLYSIS, INTRAVASCULAR
ICD-10CM # D59.6 Hemoglobinuria due to hemolysis from other external causes
D59.8 Other acquired hemolytic anemias

Infections.
Exertional hemolysis (e.g., prolonged march).
Valve hemolysis.
Microangiopathic hemolytic anemia.
Osmotic and chemical agents.
Thermal injury.
Cold agglutinins.
Venoms (snakes, spiders).
Paroxysmal nocturnal hemoglobinuria (PNH).

HEMOLYSIS, MECHANICAL
ICD-10CM # D59.4 Other nonautoimmune hemolytic anemias

Prosthetic heart valves.
Aortic stenosis.
Malignant hypertension.
Metastatic adenocarcinoma.
Traumatic exercise.
Renal transplants.
Renal cortical necrosis.
Glomerulonephritis.
Thrombotic thrombocytopenic purpura (TTP), hemolytic-uremic syndrome (HUS).
Renal vasculitis.
Scleroderma.
Diabetes mellitus.

HEMOLYSIS, OXIDATIVE, DRUG-INDUCED[46]
ICD-10CM # D59 Acquired hemolytic anemia
D59.1 Other autoimmune hemolytic anemias

AGENTS THAT CAUSE OXIDATIVE HEMOLYSIS
Therapeutic Agents
Nitrofurantoin (Furadantin).
Sulfasalazine (Azulfidine).
p-Aminosalicylic acid.
Phenazopyridine (Pyridium).
Clotrimoxazole.
Quinolones.
Phenacetin.
Rasburicase.
Dapsone and other sulfones.
Primaquine.
Recreational Drugs
Isobutyl nitrate.
Amyl nitrite.
Miscellaneous Agents
Naphthalene mothballs.
Methylene blue.
Paraquat.
Hydrogen peroxide.

HEMOPERITONEUM
ICD-10CM # K66.1 Hemoperitoneum

Ruptured Graafian follicle.
Ruptured spleen.
Ectopic pregnancy.
Traumatic laceration of liver.
Ruptured aneurysm.
Ruptured bladder.
Traumatic laceration of bowel, pancreas, uterus.

HEMOPTYSIS
ICD-10CM # R04.2 Hemoptysis

CARDIOVASCULAR
Pulmonary embolism/infarction.
Left ventricular failure.
Mitral stenosis.

AV fistula.
Severe hypertension.
Erosion of aortic aneurysm.

PULMONARY

Neoplasm (primary or metastatic).
Infection.
Pneumonia: *Streptococcus pneumoniae, Klebsiella pneumoniae, Staphylococcus aureus, Legionella pneumophila.*
Bronchiectasis.
Abscess.
TB.
Bronchitis.
Fungal infections (aspergillosis, coccidioidomycosis).
Parasitic infections (amebiasis, ascariasis, paragonimiasis).
Vasculitis: granulomatosis with polyangiitis, Churg-Strauss syndrome, Henoch-Schönlein purpura.
Goodpasture syndrome.
Trauma (needle biopsy, foreign body, right-sided heart catheterization, prolonged and severe cough).
Cystic fibrosis, bullous emphysema.
Pulmonary sequestration.
Pulmonary AV fistula.
SLE.
Idiopathic pulmonary hemosiderosis.
Drugs: aspirin, anticoagulants, penicillamine.
Pulmonary hypertension.
Mediastinal fibrosis.

OTHER

Epistaxis, trauma.
Laryngeal bleeding (laryngitis, laryngeal neoplasm).
Hematologic disorders (clotting abnormalities, DIC, thrombocytopenia).

HEMORRHAGIC CYSTITIS[90]

ICD-10CM #		
	N39.0	Urinary tract infection

DIFFERENTIAL DIAGNOSIS FOR HEMORRHAGIC CYSTITIS[20]

Infectious:
- Bacterial.
- Viral (especially BK virus, adenovirus).
- Fungal.
- Parasitic.

Trauma:
- External.
- Postsurgical (e.g., transurethral resection of the bladder).

Malignancy:
- Bladder primary.
- Bladder invasion from local/distant primary.

Vascular malformation.
Chemical exposure:
- Cyclophosphamide.
- Ifosfamide.
- Busulfan.
- Thiotepa.
- Temozolomide.
- Aniline dye.
- Ether.
- Nonoxynol-9 (accidental urethral insertion of vaginal contraceptive).

Radiation therapy history (e.g., prostate cancer, cervical cancer).
Medication induced:
- Penicillin and derivatives (via immune reaction).
- Bleomycin.
- Danazol.
- Tiaprofenic.
- Allopurinol.
- Phensuximide.
- Methenamine mandelate.
- Acetic acid.

Manifestation of systemic disease:
- Amyloidosis.
- Rheumatoid arthritis.
- Crohn disease.

[20] Bleeding localized to bladder after diagnostic workup for gross hematuria with cystoscopy, urine cytology, and upper tract imaging is without clear cause of alternative bleeding source.

HEPATIC CYSTS[82]

ICD-10CM #		
	Q44.6	Cystic disease of liver
	B67.8	Echinococcosis, unspecified, of liver

CONGENITAL HEPATIC CYSTS

Parenchymal: solitary cyst, polycystic disease.
Ductal: localized dilatation, multiple cystic dilatations of intrahepatic ducts (Caroli disease).

ACQUIRED HEPATIC CYSTS

Inflammatory cysts: retention cysts, echinococcal cyst, amebic cyst.
Neoplastic cyst.
Peliosis hepatis.

HEPATIC DYSFUNCTION, POSTOPERATIVE[26]

ICD-10CM #		
	K91.82	Postprocedural hepatic failure

CAUSES OF POSTOPERATIVE HEPATIC DYSFUNCTION

Hepatocellular Injury (predominant serum ALT elevation, with or without hyperbilirubinemia)
Acute transfusion-associated viral hepatitis.
Hepatic allograft rejection.
Hepatic artery thrombosis.
Inhalational anesthetics: halothane, others.
Ischemic hepatitis (shock liver).
Other drugs: antihypertensives (e.g., labetalol), heparin.
Unrecognized chronic liver disease: NASH, hepatitis C, other disorders.
Cholestatic Jaundice (elevated serum alkaline phosphatase ± ALT; direct hyperbilirubinemia)
Acalculous cholecystitis.
Benign postoperative cholestasis.
Bile duct injury: after cholecystectomy or liver transplantation.
Bile duct obstruction: gallstones, pancreatitis.
Cardiac bypass of prolonged duration.
Cholangitis.
Drugs: amoxicillin-clavulanic acid, chlorpromazine, erythromycin, telithromycin, trimethoprim/sulfamethoxazole, warfarin, others.
Hemobilia.
Microlithiasis (biliary sludge).
Prolonged TPN.
Sepsis.
Indirect Hyperbilirubinemia (serum alkaline phosphatase and ALT often normal)
Gilbert syndrome.
Hemolytic anemia (G6PD deficiency, other causes).
Multiple transfusions.
Resorbing hematoma.

G6PD, Glucose-6-phosphate dehydrogenase; *NASH,* nonalcoholic steatohepatitis.

HEPATIC GRANULOMAS[3]

ICD-10CM #		
	K75.3	Granulomatous hepatitis

INFECTIONS

Bacterial, spirochetal: TB and atypical mycobacterial infections, tularemia, brucellosis, leprosy, syphilis, Whipple disease, listeriosis.
Viral: mononucleosis, CMV.
Rickettsial: Q fever.
Fungal: coccidioidomycosis, histoplasmosis, cryptococcal infections, actinomycosis, aspergillosis, nocardiosis.
Parasitic: schistosomiasis, clonorchiasis, toxocariasis, ascariasis, toxoplasmosis, amebiasis.

HEPATOBILIARY DISORDERS

Primary biliary cirrhosis, granulomatous hepatitis, jejunoileal bypass.

SYSTEMIC DISORDERS

Sarcoidosis, granulomatosis with polyangiitis, inflammatory bowel disease, Hodgkin disease, lymphoma.

DRUGS/TOXINS

Beryllium, parenteral foreign material (starch, talc, silicone, etc.), phenylbutazone, α-methyldopa, procainamide, allopurinol, phenytoin, nitrofurantoin, hydralazine.

HEPATITIS, ACUTE[58]

ICD-10CM #		
	B17.8	Acute viral hepatitis, unspecified
	B15	Acute hepatitis A
	B16	Acute hepatitis B
	B17.1	Acute hepatitis C
	B17.2	Acute hepatitis E

Infectious:
- Hepatitis A, B, C, D, E.
- Epstein-Barr virus.
- Cytomegalovirus.
- Herpes simplex virus.
- Yellow fever.
- Leptospirosis.
- Q fever.

HIV.
Brucellosis.
Lyme disease.
Syphilis.
Noninfectious:
Drug induced.
Autoimmune.
Ischemic.
Acute fatty liver of pregnancy.
Acute Budd-Chiari syndrome.
Wilson disease.

HEPATITIS, CHRONIC[58]

ICD-10CM #	K73.9	Chronic hepatitis, unspecified
	B18.0	Chronic viral hepatitis B with δ-agent
	B18.2	Chronic viral hepatitis C

Chronic viral hepatitis:
Hepatitis B.
Hepatitis C.
Hepatitis D.
Autoimmune hepatitis and variant syndromes.
Hereditary hemochromatosis.
Wilson disease.
α_1-Antitrypsin deficiency.
Fatty liver and nonalcoholic steatohepatitis.
Alcoholic liver disease.
Drug-induced liver disease.
Hepatic granulomas:
Infectious.
Drug induced.
Neoplastic.
Idiopathic.

HEPATITIS, IN CHILDREN[53]

ICD-10CM #	B17.9	Acute viral hepatitis, unspecified
	K73.9	Chronic hepatitis, unspecified

CAUSES AND DIFFERENTIAL DIAGNOSIS OF HEPATITIS IN CHILDREN

Infectious
Hepatotropic viruses:
HAV.
HBV.
HCV.
HDV.
HEV.
Hepatitis non–A-E viruses.
Systemic infection that can include hepatitis:
Adenovirus.
Arbovirus.
Coxsackievirus.
Cytomegalovirus.
Enterovirus.
Epstein-Barr virus.
"Exotic" viruses (e.g., yellow fever).
Herpes simplex virus.
Human immunodeficiency virus.
Paramyxovirus.
Rubella.
Varicella zoster.
Other.

Nonviral liver infections
Abscess.
Amebiasis.
Bacterial sepsis.
Brucellosis.
Fitz-Hugh-Curtis syndrome.
Histoplasmosis.
Leptospirosis.
Tuberculosis.
Other.
Autoimmune
Autoimmune hepatitis.
Sclerosing cholangitis.
Other (e.g., systemic lupus erythematosus, juvenile rheumatoid arthritis).
Metabolic
α1-Antitrypsin deficiency.
Tyrosinemia.
Wilson disease.
Other.
Toxic
Iatrogenic or drug induced (e.g., acetaminophen).
Environmental (e.g., pesticides).
Anatomic
Choledochal cyst.
Biliary atresia.
Other.
Hemodynamic
Shock.
Congestive heart failure.
Budd-Chiari syndrome.
Other.
Nonalcoholic Fatty Liver Disease
Idiopathic.
Reye syndrome.
Other.

HEPATOMEGALY

ICD-10CM #	R16.0	Hepatomegaly, not elsewhere classified

FREQUENT JAUNDICE

Infectious hepatitis.
Toxic hepatitis.
Carcinoma: liver, pancreas, bile ducts, metastatic neoplasm to liver.
Cirrhosis.
Obstruction of common bile duct.
Alcoholic hepatitis.
Biliary cirrhosis.
Cholangitis.
Hemochromatosis with cirrhosis.

INFREQUENT JAUNDICE

CHF.
Amyloidosis.
Liver abscess.
Sarcoidosis.
Infectious mononucleosis.
Alcoholic fatty infiltration.
Nonalcoholic steatohepatitis.
Lymphoma.
Leukemia.
Budd-Chiari syndrome.
Myelofibrosis with myeloid metaplasia.
Familial hyperlipoproteinemia type 1.
Other: amebiasis, hydatid disease of liver, schistosomiasis, kala-azar *(Leishmania donovani),* Hurler syndrome, Gaucher disease, kwashiorkor.

HEPATOMEGALY, BY SHAPE OF LIVER[86]

ICD-10CM #	R16.0	Hepatomegaly, not elsewhere classified

DIFFUSELY ENLARGED AND SMOOTH

Massive
Metastatic disease.
Alcoholic liver disease with fatty infiltration.
Myeloproliferative diseases (e.g., polycythemia rubra vera, myelofibrosis).
Moderate
The above causes.
Hemochromatosis.
Hematologic disease (e.g., chronic myeloid leukemia, lymphoma).
Fatty liver (e.g., diabetes mellitus, obesity).
Infiltrative disorders (e.g., amyloid).
Mild
The above causes.
Hepatitis (viral, drugs).
Cirrhosis.
Biliary obstruction.
Granulomatous disorders (e.g., sarcoid).
HIV infection.

DIFFUSELY ENLARGED AND IRREGULAR

Metastatic disease.
Cirrhosis.
Hydatid disease.
Polycystic liver disease.

LOCALIZED SWELLINGS

Riedel lobe (a normal variant—the lobe may be palpable in the right lumbar region).
Metastasis.
Large simple hepatic cyst.
Hydatid cyst.
Hepatoma.
Liver abscess (e.g., amebic abscess).

HERMAPHRODITISM[9]

ICD-10CM #	Q56.3	Pseudohermaphroditism, unspecified
	Q56.4	Indeterminate sex, unspecified

Female Pseudohermaphroditism
Androgen exposure:
Fetal source:
21-Hydroxylase (P450 c21) deficiency.
11β-Hydroxylase (P450 c11) deficiency.
3β-Hydroxysteroid dehydrogenase II (3β-HSD II) deficiency.
Aromatase (P450arom) deficiency.
Maternal source.
Virilizing ovarian tumor.
Virilizing adrenal tumor.
Androgenic drugs.
Undetermined origin:
Associated with genitourinary and GI tract defects.

MALE PSEUDOHERMAPHRODITISM

Defects in testicular differentiation:
- Denys-Drash syndrome (mutation in WT1 gene).
- WAGR syndrome (*W*ilms tumor, *a*niridia, *g*enitourinary malformation, *r*etardation).
- Deletion of 11p13.
- Camptomelic syndrome (autosomal gene at 17q24.3-q25.1) and SOX 9 mutation.
- XY pure gonadal dysgenesis (Swyer syndrome).
- Mutation in SRY gene.
- Unknown cause.
- XY gonadal agenesis.

Deficiency of testicular hormones:
- Leydig cell aplasia.
- Mutation in LH receptor.
- Lipoid adrenal hyperplasia (P450 scc) deficiency; mutation in StAR (steroidogenic acute regulatory protein).
- 3α-HSD II deficiency.
- 17-Hydroxylase/17, 20-lyase (P450 c17) deficiency.
- Persistent Müllerian duct syndrome.
- Gene mutations, Müllerian-inhibiting substance (MIS).
- Receptor defects for MIS.

Defect in androgen action:
- 5α-Reductase II mutations.
- Androgen receptor defects:
  - Complete androgen insensitivity syndrome.
  - Partial androgen insensitivity syndrome.
  - Reifenstein and other syndromes.
  - Smith-Lemli-Opitz syndrome.

Defect in conversion of 7-dehydrocholesterol to cholesterol.

TRUE HERMAPHRODITISM

XX.
XY.
XX/XY chimeras.

HICCUPS[49]

ICD-10CM # R06.6 Hiccough

TRANSIENT HICCUPS

Sudden excitement, emotion.
Gastric distention.
Esophageal obstruction.
Alcohol ingestion.
Sudden change in temperature.

PERSISTENT OR CHRONIC HICCUPS

Toxic/metabolic: uremia, DM, hyperventilation, hypocalcemia, hypokalemia, hyponatremia, gout, fever.
Drugs: benzodiazepines, steroids, α-methyldopa, barbiturates.
Surgery/general anesthesia.
Thoracic/diaphragmatic disorders: pneumonia, lung cancer, asthma, pleuritis, pericarditis, myocardial infarction, aortic aneurysm, esophagitis, esophageal obstruction, diaphragmatic hernia or irritation.
Abdominal disorders: gastric ulcer or cancer, hepatobiliary or pancreatic disease, IBD, bowel obstruction, intraabdominal or subphrenic abscess, prostatic infection or cancer.
CNS disorders: traumatic, infectious, vascular, structural.
Ear, nose, and throat disorders: pharyngitis, laryngitis, tumor, irritation of auditory canal.
Psychogenic disorders.
Idiopathic disorders.

HILAR AND MEDIASTINAL LYMPH NODE ENLARGEMENT[34]

ICD-10CM # R59.0 Mediastinal adenopathy

DISORDERS ASSOCIATED WITH HILAR AND MEDIASTINAL LYMPH NODE ENLARGEMENT

Sarcoidosis.
Lymphoma.
Fungal disease.
Tuberculosis.
Metastatic cancer.
Silicosis, coal worker's pneumoconiosis, beryllium lung.

HIP PAIN, CHILDREN[58]

ICD-10CM #	S79.819A	Other specified injuries of unspecified hip, initial encounter
	S79.829A	Other specified injuries of unspecified thigh, initial encounter
	S79.919A	Unspecified injury of unspecified hip, initial encounter

TRAUMA

Hip or pelvis fractures.
Overuse injuries.

INFECTION

Septic arthritis.
Osteomyelitis.

INFLAMMATION

Transient synovitis.
Juvenile RA.
Rheumatic fever.

NEOPLASM

Leukemia.
Osteogenic or Ewing sarcoma.
Metastatic disease.

HEMATOLOGIC DISORDERS

Hemophilia.
Sickle cell anemia.

MISCELLANEOUS

Legg-Calvé-Perthes disease.
Slipped capital femoral epiphysis.

HIP PAIN, DIFFERENTIAL DIAGNOSIS[41]

ICD-10CM # M25.559 Pain in unspecified hip

ARTICULAR

Inflammatory joint disease
Rheumatoid arthritis.
Spondyloarthropathies.
Polymyalgia rheumatica.
Degenerative joint disease
Primary osteoarthritis.
Secondary osteoarthritis.
Metabolic joint diseases
Gout.
Pseudogout.
Ochronosis.
Hemochromatosis.
Wilson disease.
Acromegaly.
Femoroacetabular impingement
Acetabular labral tear
Infections
Tumors
- Benign:
  - Pigmented villonodular sclerosis.
  - Osteochondromatosis.
- Malignant:
  - Synovial sarcoma.
  - Synovial metastasis.

Hemarthrosis
In children:
Toxic synovitis.
Juvenile chronic arthritis.

REFERRED PAIN

Thoracolumbar spine:
- Intraabdominal structures.
- Retroperitoneal structures.

PERIARTICULAR

Bursitis:
- Trochanteric.
- Iliopsoas.
- Ischiogluteal.

Tendinitis:
- Trochanteric.
- Adductor.

Acute calcific periarthritis.
Heterotropic ossification.

OSSEOUS

Bone lesions.
Fractures.
Neoplasms.
Infection.
Osteonecrosis of the femoral head.
Paget disease.
Metabolic bone disease.
Stress fracture.
Transient osteoporosis.
In children:
- Congenital dislocation of the hip.
- Acetabular dysplasia.
- Coxa vara.
- Slipped capital femoral epiphysis.
- Legg-Calvé-Perthes disease.
- Rickets.

NEUROLOGIC

Entrapment neuropathies.
Lateral femoral cutaneous nerve (meralgia paresthetica).
Lumbar nerve root compression.
L2, L3, and L4.

VASCULAR

Atherosclerosis of aorta, iliac vessels.

HIP PAIN, IN DIFFERENT AGE GROUPS[18]

ICD-10CM # M25.559 Pain in unspecified hip

COMMON CAUSES OF HIP PAIN IN DIFFERENT AGE GROUPS

Childhood (2 to 10 yr)
Intraarticular
Developmental dislocation of the hip.
Perthes disease.
Irritable hip.
Rickets.
Periarticular
Osteomyelitis.
Referred
Abdominal.
Adolescence (10 to 18 yr)
Intraarticular
Slipped upper femoral epiphysis.
Torn labrum.
Periarticular
Trochanteric bursitis.
Snapping hip.
Osteomyelitis.
Tumors.
Referred
Abdominal.
Lumbar spine.
Early Adulthood (18 to 30 yr)
Intraarticular
Inflammatory arthritis.
Torn labrum.
Periarticular
Bursitis.
Referred
Abdominal.
Lumbar spine.
Adulthood (30 to 50 yr)
Intraarticular
Osteoarthritis.
Inflammatory arthritis.
Osteonecrosis.
Transient osteoporosis.
Periarticular
Bursitis.
Referred
Abdominal.
Lumbar spine.
Old Age (>50 yr)
Intraarticular
Osteoarthritis.
Inflammatory arthritis.
Referred
Abdominal.
Lumbar spine.

HIP PAIN WITHOUT OBVIOUS FRACTURE[7]

ICD-10CM #	R52	Pain, unspecified
	M25.559	Pain in unspecified hip

DIFFERENTIAL DIAGNOSIS OF A PAINFUL HIP WITHOUT OBVIOUS FRACTURE

Referred pain (lumbar spine, hip, or knee).
Avascular necrosis of the femoral head.
Degenerative joint disease or osteoarthritis.
Herniation of a lumbar disk.
Diskitis.
Toxic synovitis of the hip.
Septic arthritis.
Bursitis.
Tendonitis.
Ligamentous injuries of the knee or hip.
Occult fracture.
Slipped capital femoral epiphysis.
Perthes disease.
Tumor (lymphoma).
Deep venous thrombosis.
Arterial insufficiency.
Osteomyelitis.
Iliopsoas abscess.
Retroperitoneal hematoma.
Inguinal hernia.
Inguinal lymphadenopathy.
Genitourinary complaints.
Sports-related hernia.

HIRSUTISM

ICD-10CM #	L68.0	Hirsutism

Idiopathic: familial, possibly increased sensitivity to androgens.
Menopause.
Polycystic ovarian syndrome.
Drugs: androgens, anabolic steroids, methyltestosterone, minoxidil, diazoxide, phenytoin, glucocorticoids, cyclosporine.
Congenital adrenal hyperplasia.
Adrenal virilizing tumor.
Ovarian virilizing tumor: arrhenoblastoma, hilus cell tumor.
Pituitary adenoma.
Cushing syndrome.
Hypothyroidism (congenital and juvenile).
Acromegaly.
Testicular feminization.

HIV INFECTION, ANORECTAL LESIONS[58]

ICD-10CM #	B20	Human immunodeficiency virus [HIV] disease
	Z21	Asymptomatic human immunodeficiency virus [HIV] infection status

COMMON CONDITIONS

Anal fissure.
Abscess and fistula.
Hemorrhoids.
Pruritus ani.
Pilonidal disease.

COMMON STDs

Gonorrhea.
Chlamydia.
Herpes.
Chancroid.
Syphilis.
Condylomata acuminata.

ATYPICAL CONDITIONS

Infectious: TB, CMV, actinomycosis, cryptococcus.
Neoplastic: lymphoma, Kaposi sarcoma, squamous cell carcinoma.
Other: idiopathic and ulcer.

HIV INFECTION, CHEST RADIOGRAPHIC ABNORMALITIES[58]

ICD-10CM #	B20	Human immunodeficiency virus [HIV] disease
	Z21	Asymptomatic human immunodeficiency virus [HIV] infection status

DIFFUSE INTERSTITIAL INFILTRATION

Pneumocystis jiroveci.
Cytomegalovirus.
Mycobacterium tuberculosis.
Mycobacterium avium complex.
Histoplasmosis.
Coccidioidomycosis.
Lymphoid interstitial pneumonitis.

FOCAL CONSOLIDATION

Bacterial pneumonia.
Mycoplasma pneumoniae.
Pneumocystis jiroveci.
Mycobacterium tuberculosis.
Mycobacterium avium complex.

NODULAR LESIONS

Kaposi sarcoma.
Mycobacterium tuberculosis.
Mycobacterium avium complex.
Fungal lesions.
Toxoplasmosis.

CAVITARY LESIONS

Pneumocystis jiroveci.
Mycobacterium tuberculosis.
Bacterial infection.

PLEURAL EFFUSION

Kaposi sarcoma.
(Small effusion may be associated with any infection).

ADENOPATHY

Kaposi sarcoma.
Lymphoma.
Mycobacterium tuberculosis.
Cryptococcus.

PNEUMOTHORAX

Kaposi sarcoma.

HIV INFECTION, COGNITIVE IMPAIRMENT[58]

ICD-10CM # B20 Human immunodeficiency virus [HIV] disease

EARLY TO MID-STAGE HIV DISEASE

Depression.
Alcohol and substance abuse.
Medication-induced cognitive impairment.
Metabolic encephalopathies.
HIV-related cognitive impairment.

ADVANCED HIV DISEASE (CD4+ <100/MM^3)

Opportunistic infection of CNS.
Neurosyphilis.
CNS lymphoma.
Progressive multifocal leukoencephalopathy.
Depression.
Metabolic encephalopathies.
Medication-induced cognitive impairment.
Stroke.
HIV dementia.

HIV INFECTION, CUTANEOUS MANIFESTATIONS[49]

ICD-10CM # B20 Human immunodeficiency virus [HIV] disease
Z21 Asymptomatic human immunodeficiency virus [HIV] infection status

BACTERIAL INFECTION

Bacillary angiomatosis: numerous angiomatous nodules associated with fever, chills, weight loss.
Staphylococcus aureus: folliculitis, ecthyma, impetigo, bullous impetigo, furuncles, carbuncles.
Syphilis: may occur in different forms (primary, secondary, tertiary); chancre may become painful because of secondary infection.

FUNGAL INFECTION

Candidiasis: mucous membranes (oral, vulvovaginal), less commonly candida intertrigo or paronychia.
Cryptococcoses: papules or nodules that strongly resemble molluscum contagiosum; other forms include pustules, purpuric papules, and vegetating plaques.
Seborrheic dermatitis: scaling and erythema in the hair-bearing areas (eyebrows, scalp, chest, and pubic area).

ARTHROPOD INFESTATIONS

Scabies: pruritus with or without rash, usually generalized but can be limited to a single digit.

VIRAL INFECTION

Herpes simplex: vesicular lesion in clusters; perianal, genital, orofacial, or digital; can be disseminated.
Herpes zoster: painful dermatomal vesicles that may ulcerate or disseminate.
HIV: discrete erythematous macules and papules on the upper trunk, palms, and soles are the most characteristic cutaneous finding of acute HIV infection.
Human papillomavirus: genital warts (may become unusually extensive).
Kaposi sarcoma (herpesvirus): erythematous macules or papules; enlarge at varying rates; violaceous nodules or plaques; occasionally painful.
Molluscum contagiosum: discrete umbilicated papules commonly on the face, neck, and intertriginous sites (axilla, groin, or buttocks).

NONINFECTIOUS

Drug reactions: more frequent and severe in HIV patients.
Nutritional deficiencies: mainly seen in children and patients with chronic diarrhea; diffuse skin manifestations, depending upon the deficiency.
Psoriasis: scaly lesions; diffuse or localized; can be associated with arthritis.
Vasculitis: palpable purpuric eruption (can resemble septic emboli).

HIV INFECTION, ESOPHAGEAL DISEASE

ICD-10CM # B20 Human immunodeficiency virus [HIV] disease
K21.9 Gastro-esophageal reflux disease without esophagitis

Candida infection.
Cytomegalovirus infection.
Aphthous ulcer.
Herpes simplex.

HIV INFECTION, HEPATIC DISEASE[58]

ICD-10CM # B20 Human immunodeficiency virus [HIV] disease

VIRUSES

Hepatitis A.
Hepatitis B.
Hepatitis C.
Hepatitis D (with HBV).
Epstein-Barr virus.
Cytomegalovirus.
Herpes simplex virus.
Adenovirus.
Varicella-zoster virus.

MYCOBACTERIA

Mycobacterium avium complex.
Mycobacterium tuberculosis.

FUNGI

Histoplasma capsulatum.
Cryptococcus neoformans.
Coccidioides immitis.
Candida albicans.
Pneumocystis jiroveci.
Penicillium marneffei.

PROTOZOA

Toxoplasma gondii.
Cryptosporidium parvum.
Microsporida.
Schistosoma.

BACTERIA

Bartonella henselae (peliosis hepatis).

MALIGNANCY

Kaposi sarcoma (HHV-8).
Non-Hodgkin lymphoma.
Hepatocellular carcinoma.

MEDICATIONS

Zidovudine.
Didanosine.
Ritonavir.
Other HIV-1 protease inhibitors.
Fluconazole.
Macrolide antibiotics.
Isoniazid.
Rifampin.
Trimethoprim-sulfamethoxazole.

HIV INFECTION, LOWER GI TRACT DISEASE[58]

ICD-10CM # B20 Human immunodeficiency virus [HIV] disease

CAUSES OF ENTEROCOLITIS

Bacteria
Campylobacter jejuni and other spp.
Salmonella spp.
Shigella flexneri.
Aeromonas hydrophila.
Plesiomonas shigelloides.
Yersinia enterocolitica.
Vibrio spp.
Mycobacterium avium complex.
Mycobacterium tuberculosis.
Escherichia coli (enterotoxigenic, enteroadherent).
Bacterial overgrowth.
Clostridium difficile (toxin).
Parasites
Cryptosporidium parvum.
Microsporida (*Enterocytozoon bieneusi, Septata intestinalis*).

Isospora belli.
Entamoeba histolytica.
Giardia lamblia.
Cyclospora cayetanensis.
Viruses
Cytomegalovirus.
Adenovirus.
Calicivirus.
Astrovirus.
Picobirnavirus.
Human immunodeficiency virus.
Fungi
Histoplasma capsulatum.

CAUSES OF PROCTITIS

Bacteria
Chlamydia trachomatis.
Neisseria gonorrhoeae.
Treponema pallidum.
Viruses
Herpes simplex.
Cytomegalovirus.

HIV INFECTION, MUSCULOSKELETAL DISORDERS[71]

ICD-10CM # B20 Human immunodeficiency virus [HIV] disease

MUSCULOSKELETAL DISORDERS ASSOCIATED WITH HIV INFECTION

Joints, Ligaments, and Soft Tissues
Painful articular syndrome.
HIV-associated arthritis.
Reactive arthritis.
Septic arthritis.
Psoriatic arthritis.
Diffuse infiltrative lymphocytosis syndrome.
Systemic lupus erythematosus.
Rheumatoid arthritis.
Vasculitis (polyarteritis nodosa, drug induced).
Immune reconstitution inflammatory syndrome.
Cellulitis and soft tissue abscesses.
Fasciitis (including necrotizing fasciitis).
Bursitis and tenosynovitis.
Muscles
HIV myopathy.
Nucleoside reverse transcriptase inhibitor (NRTI) myopathy.
Muscle infections (pyomyositis, toxoplasmosis).
Other (rhabdomyolysis, non-Hodgkin lymphoma, myasthenia gravis, nemaline [rod] myopathy, and inclusion body myositis).
Bones
Osteomyelitis.
Osteopenia and osteoporosis.
Osteonecrosis.
Hypertrophic osteoarthropathy.
Opportunistic Infections, HIV/AIDS-Defining Neoplastic Disorders, and Other Disorders Affecting Any Part of the Musculoskeletal System in HIV Infection
Neoplasia:
- Kaposi sarcoma.
- Non-Hodgkin lymphoma.
- Hodgkin lymphoma.
- Leiomyosarcoma.
- Ewing sarcoma.

Infection:
- Tuberculosis.
- Disseminated *Mycobacterium avium* complex infection.
- Coccidioidomycosis.
- Toxoplasmosis.
- Bacillary angiomatosis.

Other:
- HIV-related lipodystrophy.
- HIV wasting syndrome.

HIV INFECTION, OCULAR MANIFESTATIONS[82]

ICD-10CM # B20 Human immunodeficiency virus [HIV] disease
Z21 Asymptomatic human immunodeficiency virus [HIV] infection status

EYELIDS

Molluscum contagiosum.
Kaposi sarcoma.

CORNEA/CONJUNCTIVA

Keratoconjunctivitis sicca.
Bacterial/fungal ulcerative keratitis.
Herpes simplex.
Herpes zoster ophthalmicus.
Conjunctival microvasculopathy.
Kaposi sarcoma.

RETINA, CHOROID, AND VITREOUS

Microvasculopathy.
Endophthalmitis.
Cytomegalovirus retinitis.
Acute retinal necrosis.
Syphilis.
Toxoplasmosis.
Pneumocystis choroidopathy.
Cryptococcosis.
Mycobacterial infection.
Intraocular lymphoma.
Candidiasis.
Histoplasmosis.

DRUGS ASSOCIATED WITH OCULAR TOXICITY

Rifabutin.
Didanosine.

NEUROOPHTHALMIC

Disc edema.
Primary or secondary optic neuropathy.
Cranial nerve palsies.

ORBITAL

Lymphoma.
Infection.
Pseudotumor.

HIV INFECTION, PULMONARY DISEASE[10, 58]

ICD-10CM # B20 Human immunodeficiency virus [HIV] disease
I28.8 Other diseases of pulmonary vessels

RADIOGRAPHIC APPEARANCE

Diffuse Interstitial Infiltrates
Pneumocystis jiroveci.
Mycobacterium tuberculosis, especially with advanced human immunodeficiency virus disease.
Histoplasma capsulatum.
Coccidioides spp.
Cryptococcus neoformans.
Toxoplasma gondii.
Cytomegalovirus.
Influenza.
Lymphocytic interstitial pneumonitis.
Abacavir hypersensitivity.
Focal Consolidation
Pyogenic bacterial pneumonia from *Streptococcus pneumoniae, Haemophilus influenzae.*
M. tuberculosis.
Legionella spp.
Rhodococcus equi.
Hilar Adenopathy
M. tuberculosis.
H. capsulatum.
Coccidioides spp.
Non-Hodgkin or Hodgkin lymphoma.
Mycobacterium avium complex.
Cavitary Disease
Pyogenic bacterial pneumonia from *Pseudomonas aeruginosa, Staphylococcus aureus*, Enterobacteriaceae.
M. tuberculosis.
C. neoformans.
R. equi.
Aspergillus spp.
Nocardia spp.
Mycobacterium avium complex.
P. jiroveci.
Nodules or Masses
M. tuberculosis.
C. neoformans.
Aspergillus spp.
H. capsulatum.
Nocardia spp.
Non-Hodgkin lymphoma.
Kaposi sarcoma.
Lung cancer.
Normal Radiograph
P. jiroveci.
M. tuberculosis.

CAUSES

Mycobacterial
M. tuberculosis.
M. kansasii.
M. avium complex.
Other nontuberculous mycobacteria.
Other Bacterial
Streptococcus pneumoniae.
Staphylococcus aureus.
Haemophilus influenzae.
Enterobacteriaceae.
Pseudomonas aeruginosa.
Moraxella catarrhalis.
Group A *Streptococcus.*
Nocardia spp.
Rhodococcus equi.
Chlamydia pneumoniae.
Fungal
Pneumocystis carinii.

Cryptococcus neoformans.
Histoplasma capsulatum.
Coccidioides immitis.
Aspergillus spp.
Blastomyces dermatitidis.
Penicillium marneffei.
Viral
Cytomegalovirus.
Herpes simplex virus.
Adenovirus.
Respiratory syncytial virus.
Influenza viruses.
Parainfluenza virus.
Other
Toxoplasma gondii.
Strongyloides stercoralis.
Kaposi sarcoma.
Lymphoma.
Lung cancer.
Lymphocytic interstitial pneumonitis.
Nonspecific interstitial pneumonitis.
Bronchiolitis obliterans with organizing pneumonia.
Pulmonary hypertension.
Emphysema-like or bullous disease.
Pneumothorax.
Congestive heart failure.
Diffuse alveolar damage.
Pulmonary embolus.

HOARSENESS

ICD-10CM # R49.8 Other voice and resonance disorders

Allergic rhinitis.
Infections (laryngitis, epiglottitis, tracheitis, croup).
Vocal cord polyps.
Voice strain.
Irritants (tobacco smoke).
Vocal cord trauma (intubation, surgery).
Neoplastic involvement of vocal cord (primary or metastatic).
Neurologic abnormalities (multiple sclerosis, ALS, parkinsonism).
Endocrine abnormalities (puberty, menopause, hypothyroidism).
Other (laryngeal webs or cysts, psychogenic, muscle tension abnormalities).

HYDROCEPHALUS

ICD-10CM # G91.1 Obstructive hydrocephalus

Head trauma.
Brain neoplasm (primary or metastatic).
Spinal cord tumor.
Cerebellar infarction.
Exudative or granulomatous meningitis.
Cerebellar hemorrhage.
Subarachnoid hemorrhage.
Aqueductal stenosis.
Third ventricle colloid cyst.
Hindbrain malformation.
Viral encephalitis.
Metastases to leptomeninges.

HYPERCALCEMIA

ICD-10CM # E83.52 Hypercalcemia

Malignancy: increased bone resorption via osteoclast-activating factors, secretion of PTH-like substances, prostaglandin E2, direct erosion by tumor cells, transforming growth factors, colony-stimulating activity. Hypercalcemia is common in the following neoplasms:
  Solid tumors: breast, lung, pancreas, kidneys, ovary.
  Hematologic cancers: myeloma, lymphosarcoma, adult T-cell lymphoma, Burkitt lymphoma.
Hyperparathyroidism: increased bone resorption, GI absorption, and renal absorption; etiology:
  Parathyroid hyperplasia, adenoma.
  Hyperparathyroidism or renal failure with secondary hyperparathyroidism.
Granulomatous disorders: increased GI absorption (e.g., sarcoidosis).
Paget disease: increased bone resorption, seen only during periods of immobilization.
Vitamin D intoxication, milk-alkali syndrome; increased GI absorption.
Thiazides: increased renal absorption.
Other causes: familial hypocalciuric hypercalcemia, thyrotoxicosis, adrenal insufficiency, prolonged immobilization, vitamin A intoxication, recovery from acute renal failure, lithium administration, pheochromocytoma, disseminated SLE.

HYPERCALCEMIA, MALIGNANCY-INDUCED

ICD-10CM # E83.52 Hypercalcemia

Lung carcinoma	(6% frequency, 35% of hypercalcemic cases)
Breast carcinoma	(10% frequency, 25% of hypercalcemic cases)
Multiple myeloma	(33% frequency, 10% of hypercalcemic cases)
Lymphoma	(4% of hypercalcemic cases)
Genitourinary cancer	(6% of hypercalcemic cases)

HYPERCAPNIA, PERSISTENT[82]

ICD-10CM # R06.00 Dyspnea, unspecified
R06.09 Other forms of dyspnea
R06.89 Other abnormalities of breathing

Hypercapnia with normal lungs: CNS disturbances (CVA, parkinsonism, encephalitis), metabolic alkalosis, myxedema, primary alveolar hypoventilation, spinal cord lesions.
Diseases of the chest wall (e.g., kyphoscoliosis, ankylosing spondylitis).
Neuromuscular disorders (e.g., myasthenia gravis, Guillain-Barré syndrome, amyotrophic lateral sclerosis, muscular dystrophy, poliomyelitis).
COPD.

HYPERCOAGULABLE STATE, ASSOCIATED DISORDERS[45]

ICD-10CM # D68.69 Other thrombophilia

Systemic lupus erythematosus in association with the presence of a lupus anticoagulant or antiphospholipid antibodies.

MALIGNANCY

Disease-related: includes migratory superficial thrombophlebitis (Trousseau syndrome), nonbacterial thrombotic endocarditis, thrombosis associated with chronic DIC, thrombotic microangiopathy.
Treatment-related: associated with the administration of various chemotherapeutic agents (L-asparaginase, mitomycin, some adjuvant chemotherapeutic agents for treatment of breast cancer, thalidomide or lenalidomide in conjunction with high doses of dexamethasone).
Infusion of prothrombin complex concentrates.
Nephrotic syndrome.
Heparin-induced thrombocytopenia.
Myeloproliferative disorders.
Paroxysmal nocturnal hemoglobinuria.

DIC, Disseminated intravascular coagulopathy.

HYPERGASTRINEMIA

ICD-10CM # E16.4 Abnormal secretion of gastrin

Decreased gastrin release inhibition from medications (proton pump inhibitors [PPIs], H_2 receptor antagonists), vagotomy.
Chronic renal failure.
Hypochlorhydria due to atrophic gastritis, gastric carcinoma, pernicious anemia.
Gastrinoma (Zollinger-Ellison syndrome).
Pyloric obstruction.
Hyperplasia of antral G cells.
RA.

HYPERHIDROSIS[9]

ICD-10CM # R61 Generalized hyperhidrosis

CORTICAL

Emotional.
Familial dysautonomia.
Congenital ichthyosiform erythroderma.
Epidermolysis bullosa.
Nail-patella syndrome.
Jadassohn-Lewandowsky syndrome.
Pachyonychia congenita.
Palmoplantar keratoderma.

HYPOTHALAMIC

Drugs
Antipyretics.
Emetics.
Insulin.
Meperidine.
Exercise Infection
Defervescence.
Chronic illness.

Metabolic
Debility.
DM.
Hyperpituitarism.
Hyperthyroidism.
Hypoglycemia.
Obesity.
Porphyria.
Pregnancy.
Rickets.
Infantile scurvy.
Cardiovascular
Heart failure.
Shock.
Vasomotor
Cold injury.
Raynaud phenomenon.
RA.
Neurologic
Abscess.
Familial dysautonomia.
Postencephalitic.
Tumor.
Miscellaneous
Chédiak-Higashi syndrome.
Compensatory.
Phenylketonuria.
Pheochromocytoma.
Vitiligo.
Medullary
Physiologic gustatory sweating.
Encephalitis.
Granulosis rubra nasi.
Syringomyelia.
Thoracic sympathetic trunk injury.
Spinal
Cord transection.
Syringomyelia.
Changes in Blood Flow
Mallucci syndrome.
Arteriovenous fistula.
Klippel-Trenaunay syndrome.
Glomus tumor.
Blue rubber bleb nevus syndrome.

HYPERKALEMIA

ICD-10CM # E87.5 Hyperkalemia

Pseudohyperkalemia.
- Hemolyzed specimen.
- Severe thrombocytosis (platelet count 0.106 ml).
- Severe leukocytosis (white blood cell count 0.105 ml).
- Fist clenching during phlebotomy.

Excessive potassium intake (often in setting of impaired excretion).
- Potassium replacement therapy.
- High-potassium diet.
- Salt substitutes with potassium.
- Potassium salts of antibiotics.

Decreased renal excretion.
- Potassium-sparing diuretics (e.g., spironolactone, triamterene, amiloride).
- Renal insufficiency.
- Mineralocorticoid deficiency.
- Hyporeninemic hypoaldosteronism.
- Tubular unresponsiveness to aldosterone (e.g., SLE, multiple myeloma, sickle cell disease).
- Type 4 RTA.
- ACE inhibitors.
- Heparin administration.
- NSAIDs.
- Trimethoprim-sulfamethoxazole.
- Beta-blockers.
- Pentamidine.

Redistribution (excessive cellular release):
- Acidemia (each 0.1 decrease in pH increases the serum potassium by 0.4 to 0.6 mEq/L). Lactic acidosis and ketoacidosis cause minimal redistribution.
- Insulin deficiency.
- Drugs (e.g., succinylcholine, markedly increased digitalis level, arginine, beta-adrenergic blockers).
- Hypertonicity.
- Hemolysis.
- Tissue necrosis, rhabdomyolysis, burns.
- Hyperkalemic periodic paralysis.

HYPERKALEMIA, DRUG-INDUCED[88]

ICD-10CM # E87.5 Hyperkalemia

IMPAIRED RENIN-ALDOSTERONE ELABORATION/FUNCTION

Cyclooxygenase inhibitors (NSAIDs).
β-Adrenergic antagonists.
Spironolactone.
Angiotensin-converting enzyme inhibitors and angiotensin II receptor blockers.
Heparin.

INHIBITORS OF RENAL POTASSIUM SECRETION

Potassium-sparing diuretics (amiloride, triamterene).
Trimethoprim.
Pentamidine.
Cyclosporine.
Digitalis overdose.
Lithium.

ALTERED POTASSIUM DISTRIBUTION

Insulin antagonists (somatostatin, diazoxide).
β-Adrenergic antagonists.
α-Adrenergic agonists.
Hypertonic solutions.
Digitalis.
Succinylcholine.
Arginine hydrochloride, lysine hydrochloride.

HYPERKALEMIA IN CHILDREN[79]

ICD-10CM # E87.5 Hyperkalemia

MOST RELEVANT CAUSES OF HYPERKALEMIA IN PEDIATRIC PATIENTS

Pseudohyperkalemia
Improper collection of blood.
Hematologic disorders: leukocytosis, thrombocytosis, spherocytosis.
Transcellular Shift of Potassium
Acidosis.
Insulin deficiency.
Hyperosmolality.
Exercise with nonselective β-blockers.
Familial hyperkalemic periodic paralysis.
Increased Potassium Load
From exogenous origin: pharmacologic supplements.
From endogenous origin (cellular lysis): burns, trauma, intravascular hemolysis, rhabdomyolysis, tumor mass destruction.
Decreased Urinary Excretion
Renal failure.
Mineralocorticoid deficiency.
Addison disease.
Hypoaldosteronism.
Mineralocorticoid resistance.
Type 1 and type 2 pseudohypoaldosteronism.
Renal tubular acidosis: type 4 and hyperkalemic form of type 1.
"Hyperkalemic" drugs: potassium-sparing diuretics, trimethoprim, calcineurin inhibitors, blockers of the renin angiotensin aldosterone system.

HYPERKINETIC MOVEMENT DISORDERS[67]

ICD-10CM #	F90.8	Attention-deficit hyperactivity disorder, other type
	E83.00	Disorder of copper metabolism, unspecified
	E83.01	Wilson disease
	E83.09	Other disorders of copper metabolism
	G24.02	Drug induced acute dystonia
	G24.1	Genetic torsion dystonia

Chorea, choreoathetosis: drug-induced, Huntington chorea, Sydenham chorea.
Tardive dyskinesia (e.g., phenothiazines).
Hemiballismus (lacunar CVA near subthalamic nuclei in basal ganglia, metastatic lesions, toxoplasmosis [in AIDS]).
Dystonia (idiopathic, familial, drug-induced [prochlorperazine, metoclopramide]), Wilson disease.
Liver failure.
Thyrotoxicosis.
SLE, polycythemia.

HYPERMAGNESEMIA

ICD-10CM #	E83.40	Disorders of magnesium metabolism, unspecified
	E83.41	Hypermagnesemia

Renal failure (decreased GFR).
Decreased renal excretion secondary to salt depletion.
Abuse of antacids and laxatives containing magnesium in patients with renal insufficiency.

Endocrinopathies (deficiency of mineralocorticoid or thyroid hormone).
Increased tissue breakdown (rhabdomyolysis).
Redistribution: acute DKA, pheochromocytoma.
Other: lithium, volume depletion, familial hypocalciuric hypercalcemia.

HYPEROSTOSIS, CORTICAL BONE[36]

ICD-10CM # M48.19 Ankylosing hyperostosis [Forestier], multiple sites in spine

DISORDERS ASSOCIATED WITH HYPEROSTOSIS OF CORTICAL BONE

Progressive diaphyseal dysplasia.
Endosteal hyperostosis.
Pachydermoperiostosis.
Hypertrophic osteoarthropathy.
Thyroid acropachy.
Hypervitaminosis A.
Paget disease.
Infantile cortical hyperostosis.

HYPERPHOSPHATEMIA

ICD-10CM # E83.30 Disorder of phosphorus metabolism, unspecified

Excessive phosphate administration.
Excessive oral intake or IV administration.
Laxatives containing phosphate (phosphate tablets, phosphate enemas).
Decreased renal phosphate excretion.
Acute or chronic renal failure.
Hypoparathyroidism or pseudohypoparathyroidism.
Acromegaly, thyrotoxicosis.
Bisphosphonate therapy.
Tumor calcinosis.
Sickle cell anemia.
Transcellular shift out of cells.
Chemotherapy of lymphoma or leukemia, tumor lysis syndrome, hemolysis.
Acidosis.
Rhabdomyolysis, malignant hyperthermia.
Artifact: in vitro hemolysis.
Pseudohyperphosphatemia: hyperlipidemia, paraproteinemia, hyperbilirubinemia.

HYPERPHOSPHATEMIA IN CHILDREN[79]

ICD-10CM # E83.30 Disorder of phosphorus metabolism, unspecified

CAUSES OF HYPERPHOSPHATEMIA

Impaired Renal Excretion of Phosphate
Renal insufficiency.
Hypoparathyroidism, pseudohypoparathyroidism.
Transient parathyroid resistance of infancy.
Acromegaly.
Tumoral calcinosis.
Hyperthyroidism.
Juvenile hypogonadism.
High ambient temperature.
Heparin.
Bisphosphonate etidronate.
Increased Phosphate Intake
Exogenous Loads
Phosphate salts: laxatives and enemas.
Vitamin D intoxication.
Blood transfusion.
White phosphorus burns.
Liposomal amphotericin B.
Fosphenytoin.
Parenteral phosphate.
Endogenous Loads
Crush injury.
Rhabdomyolysis.
Cytotoxic therapy of neoplasms: tumor lysis.
Hemolysis.
Malignant hyperthermia.
Catabolic states.
Lactic acidosis.
Fulminant hepatitis.
Transcellular Shift of Phosphate
Cellular shift in diabetes ketoacidosis.
Metabolic acidosis.
Respiratory acidosis.
Miscellaneous
Hyperostosis.

HYPERPIGMENTATION[14]

ICD-10CM # L81.4 Other melanin hyperpigmentation

Addison disease.[21]
Arsenic ingestion.
ACTH- or MSH-producing tumors (e.g., oat cell carcinoma of the lung).
Drug induced (e.g., antimalarials, some cytotoxic agents).
Hemochromatosis ("bronze" diabetes).
Malabsorption syndrome (Whipple disease and celiac sprue).
Melanoma.
Melanotropic hormone injection.
Pheochromocytoma.
Porphyrias (porphyria cutanea tarda and variegate porphyria).
Pregnancy.
Progressive systemic sclerosis and related conditions.
PUVA therapy (psoralen administration) for psoriasis and vitiligo.

ACTH, Adrenocorticotropic hormone; *MSH,* melanocyte-stimulating hormone; *PUVA,* psoralen plus ultraviolet A.
[21]Accentuation on sun-exposed surfaces.

HYPERPROLACTINEMIA[62]

ICD-10CM # E22.1 Hyperprolactinemia

PHYSIOLOGIC

Pregnancy.
Lactation.
Stress.
Sleep.
Coitus.
Exercise.

PATHOLOGIC

Hypothalamic-Pituitary Stalk Damage
Tumors: craniopharyngioma, suprasellar pituitary mass extension, meningioma, dysgerminoma, hypothalamic metastases.
Granulomas.
Infiltrations.
Rathke cyst.
Irradiation.
Trauma: pituitary stalk section, sellar surgery, head trauma.
Pituitary
Prolactinoma.
Acromegaly.
Macroadenoma (compressive).
Idiopathic.
Plurihormonal adenoma.
Lymphocytic hypophysitis or parasellar mass.
Macroprolactinemia.
Systemic Disorders
Chronic renal failure.
Polycystic ovary syndrome.
Cirrhosis.
Pseudocyesis.
Epileptic seizures.
Cranial irradiation.
Chest: neurogenic chest wall trauma, surgery, herpes zoster.

PHARMACOLOGIC

Neuropeptide
Thyrotropin-releasing hormone.
Drug-Induced Hypersecretion
Dopamine receptor blockers:
Phenothiazines: chlorpromazine, perphenazine.
Butyrophenones: haloperidol.
Thioxanthenes.
Metoclopramide.
Dopamine synthesis inhibitors:
α-Methyldopa.
Catecholamine depleters:
Reserpine.
Cholinergic Agonist
Physostigmine.
Antihypertensives
Labetalol.
Reserpine.
Verapamil.
H_2 Antihistamines
Cimetidine.
Ranitidine.
Estrogens
Oral contraceptives.
Oral contraceptive withdrawal.
Anticonvulsant
Phenytoin.
Anesthetics
Neuroleptics
Chlorpromazine.
Risperidone.
Promazine.
Promethazine.
Trifluoperazine.
Fluphenazine.
Butaperazine.
Perphenazine.
Thiethylperazine.

Thioridazine.
Haloperidol.
Pimozide.
Thiothixene.
Molindone.
Opiates and Opiate Antagonists
Heroin.
Methadone.
Apomorphine.
Morphine.
Antidepressants
Tricyclic antidepressants: chlorimipramine, amitriptyline.
Selective serotonin reuptake inhibitors: fluoxetine.

HYPERSPLENISM, ASSOCIATED CONDITIONS

ICD-10CM # D73.1 Hypersplenism

Cirrhosis.
Portal vein thrombosis.
Myeloproliferative diseases.
Lymphomas.
Leukemias.
Splenic vein thrombosis.
Autoimmune disease.
Sickle cell disease.
Thalassemias.
Gaucher disease.
Niemann-Pick disease.

HYPERTENSION, ADRENOCORTICAL CAUSES[62]

ICD-10CM # I15.8 Other secondary hypertension

LOW RENIN AND HIGH ALDOSTERONE

Primary Aldosteronism

Aldosterone-producing adenoma (APA)	35% of cases
Bilateral idiopathic hyperplasia (IHA)	60% of cases
Primary (unilateral) adrenal hyperplasia	2% of cases
Aldosterone-producing adrenocortical carcinoma	<1% of cases
Familial hyperaldosteronism (FH)	
Glucocorticoid-remediable aldosteronism (FH type I)	<1% of cases
FH type II (APA or IHA)	<2% of cases
Ectopic aldosterone-producing adenoma or carcinoma	<0.1% of cases

LOW RENIN AND LOW ALDOSTERONE

Hyperdeoxycorticosteronism
Congenital adrenal hyperplasia:
  11β-Hydroxylase deficiency.
  17α-Hydroxylase deficiency.
Deoxycorticosterone-producing tumor.
Primary cortisol resistance.
Apparent mineralocorticoid excess (AME)/11β-HSD[22] deficiency.
  Genetic: Type 1 AME.
Acquired: licorice or carbenoxolone ingestion (type 1 AME), Cushing syndrome (type 2 AME).
Cushing Syndrome
Exogenous glucocorticoid administration—most common cause.
Endogenous:
  ACTH[23] -dependent—85% of cases: pituitary, ectopic.
  ACTH-independent—15% of cases: unilateral adrenal disease (adenoma or carcinoma), bilateral adrenal disease (massive macronodular hyperplasia [rare], primary pigmented nodular adrenal disease [rare]).

[22] *HSD,* Hydroxysteroid dehydrogenase
[23] *ACTH,* Adrenocorticotropin hormone

HYPERTENSION, ENDOCRINE CAUSES[62]

ICD-10CM # I15.8 Other secondary hypertension

ADRENAL-DEPENDENT CAUSES

Pheochromocytoma.
Primary aldosteronism.
Hyperdeoxycorticosteronism:
  Congenital adrenal hyperplasia: 11β-hydro xylase deficiency, 17α-hydroxylase deficiency.
  Deoxycorticosterone-producing tumor.
  Primary cortisol resistance.
Cushing syndrome.

AME/11β-HSD (HYDROXYSTEROID DEHYDROGENASE) DEFICIENCY

Genetic:
  Type 1 apparent mineralocorticoid excess (AME).
Acquired:
  Licorice or carbenoxolone ingestion (type 1 AME).
  Cushing syndrome (type 2 AME).

THYROID-DEPENDENT CAUSES

Hypothyroidism.
Hyperthyroidism.

PARATHYROID-DEPENDENT CAUSES

Hyperparathyroidism.

PITUITARY-DEPENDENT CAUSES

Acromegaly.
Cushing syndrome.

HYPERTENSION, IN CHILDREN[7]

ICD-10CM # I10 Essential (primary) hypertension

PRIMARY

Essential hypertension.

SECONDARY

Renal
Glomerulonephritis.
Henoch-Schönlein purpura.
Pyelonephritis.
Obstruction of reflux.
Polycystic kidney disease.
Diabetic nephropathy.
Trauma.
Renal transplant or hemodialysis.
Tuberous sclerosis.
Systemic lupus nephritis.
Endocrine
Pheochromocytoma.
Cushing syndrome.
Congenital adrenal hyperplasia.
Corticosteroid treatment.
Hyperthyroidism.
Neuroblastoma.
Ovarian tumor.
Cardiac
Congestive heart failure.
Coarctation of the aorta.
Vascular
Hemolytic-uremic syndrome.
Kawasaki syndrome.
Renal artery thrombosis or stenosis.
Neurologic
CNS tumor or infection.
CNS trauma or abuse.
Increased intracranial pressure.
Guillain-Barré syndrome.
Neoplastic
Neuroblastoma.
Wilms tumor.
Pheochromocytoma.
Adrenal carcinoma.
Drugs
Corticosteroids.
Cocaine.
Sympathomimetics.
Oral contraceptives.
Phencyclidine.
Beta-blocker or clonidine withdrawal.
Lead, mercury.
Others
Iatrogenic fluid overload.
Volume overload from end-stage renal disease.

HYPERTENSION, RESISTANT[79]

ICD-10CM # I10 Essential (primary) hypertension
ICD-10CM # I15 Secondary hypertension

CAUSES OF RESISTANT HYPERTENSION

Pseudoresistance:
  White coat hypertension or office elevations.
  Pseudohypertension in older patients.
  Use of small cuff on very obese arm.
Nonadherence to therapeutic regimen.
Volume overload.

Drug-related causes:
- Antihypertensive drug dosage too low.
- Wrong type of diuretic.
- Inappropriate combinations of antihypertensive drugs.

Drug actions and interactions:
- Sympathomimetics.
- Nasal decongestants.
- Appetite suppressants.
- Cocaine.
- Caffeine.
- Oral contraceptives.
- Adrenal steroids.
- Licorice (may be found in chewing tobacco).
- Cyclosporine, tacrolimus.
- Erythropoiesis-stimulating agents (ESAs) and erythropoietin.
- Antidepressants.
- Nonsteroidal antiinflammatory drugs.

Concomitant conditions:
- Obesity.
- Sleep apnea.
- Ethanol intake >1 oz (30 ml)/day.
- Anxiety, hyperventilation.

Secondary causes of hypertension:
- Renovascular hypertension.
- Primary aldosteronism.
- Pheochromocytoma.
- Hypothyroidism.
- Hyperthyroidism.
- Hyperparathyroidism.
- Aortic coarctation.
- Renal disease.

HYPERTENSIVE CRISIS SYNDROMES[88]

ICD-10CM # I13 Hypertensive heart and renal disease
I15 Secondary hypertension

Malignant hypertension.
Nonmalignant hypertension with target organ disorders:
- Patient requiring emergency surgery with poorly controlled hypertension.
- Hyperviscosity syndrome.
- Postoperative patient.
- Renal transplant patient: acute rejection, transplant renal artery stenosis.
- Quadriplegic patient with autonomic hyperreflexia.
- Severe burns.
- Acute aortic dissection.
- Intracranial hemorrhage, ischemic stroke, or subarachnoid hemorrhage.
- Hypertensive encephalopathy.
- Myocardial ischemia/acute left ventricular failure.
- Preeclampsia/eclampsia.
- Antiphospholipid antibody syndrome.
- Acute renal failure:
  - Scleroderma renal crisis.
  - Chronic glomerulonephritis.
  - Reflux nephropathy.
  - Analgesic nephropathy.
  - Acute glomerulonephritis.
  - Radiation nephritis.
  - Ask-Upmark kidney.
  - Chronic lead intoxication.
- Renovascular hypertension:
  - Fibromuscular dysplasia.
  - Atherosclerosis.
- Endocrine hypertension:
  - Congenital adrenal hyperplasia.
  - Pheochromocytoma.
  - Oral contraceptives.
  - Aldosteronism.
  - Cushing disease.
  - Systemic vasculitis.
  - Atheroembolic renal crisis.
- Drugs:
  - Oral contraceptives.
  - Nonsteroidal antiinflammatory agents.
  - Atropine.
  - Corticosteroids.
  - Sympathomimetics.
  - Cyclosporine.
  - Erythropoietin.
- Lead intoxication.
- Catecholamine excess states:
  - Pheochromocytoma.
  - MAO/tyramine interaction.
  - Antihypertensive withdrawal.
  - Cocaine intoxication, sympathomimetic overdose.

HYPERTENSIVE ENCEPHALOPATHY[70]

ICD-10CM # I67.4 Hypertensive encephalopathy

Ischemic stroke.
Intracerebral hemorrhage.
Subarachnoid hemorrhage.
Subdural hematoma.
Epidural hematoma.
Central nervous vasculitis.
Brain mass.
Seizure disorder.
Central nervous system infection.
Drug toxicity.
Withdrawal syndrome.

HYPERTRICHOSIS[17]

ICD-10CM # L68.0 Hirsutism
L68.1 Acquired hypertrichosis lanuginosa
L68.3 Polytrichia
L68.9 Hypertrichosis, unspecified
Q84.1 Congenital morphological disturbances of hair, not elsewhere classified

DRUGS

Dilantin.
Streptomycin.
Hexachlorobenzene.
Penicillamine.
Diazoxide.
Minoxidil.
Cyclosporine.

SYSTEMIC ILLNESS

Hypothyroidism.
Anorexia nervosa.
Malnutrition.
Porphyria.
Dermatomyositis.

IDIOPATHIC

HYPERTROPHIC OSTEOARTHROPATHY

ICD-10CM # M89.40 Other hypertrophic osteoarthropathy, unspecified site

Idiopathic.
Pulmonary disease (e.g., pulmonary fibrosis, cystic fibrosis, sarcoidosis).
Bronchogenic carcinoma.
AIDS.
GI neoplasm (e.g., esophagus, colon).
Hepatic neoplasm, cirrhosis.
Cardiovascular diseases, aortic aneurysm, aortic prosthesis.
Congenital cyanotic heart disease, patent ductus arteriosus.
Pulmonary infections, bacterial endocarditis, amebic dysentery.
Inflammatory bowel disease.
Connective tissue diseases.
Lymphomas.
Thyroid acropachy.

HYPERVENTILATION, PERSISTENT[82]

ICD-10CM # R06.4 Hyperventilation

Fibrotic lung disease.
Metabolic acidosis (e.g., diabetes, uremia).
CNS disorders (midbrain and pontine lesions).
Hepatic coma.
Salicylate intoxication.
Fever.
Sepsis.
Psychogenic (e.g., anxiety).

HYPOCALCEMIA

ICD-10CM # E83.51 Hypocalcemia

Renal insufficiency: hypocalcemia caused by:
- Increased calcium deposits in bone and soft tissue secondary to increased serum phosphate level.
- Decreased production of 1,25-dihydroxyvitamin D.
- Excessive loss of 25-OHD (nephrotic syndrome).

Hypoalbuminemia: each decrease in serum albumin (g/L) will decrease serum calcium by 0.8 mg/dl but will not change free (ionized) calcium.
Vitamin D deficiency:
- Malabsorption (most common cause).
- Inadequate intake.
- Decreased production of 1,25-dihydroxyvitamin D (vitamin D–dependent rickets, renal failure).
- Decreased production of 25-OHD (parenchymal liver disease).
- Accelerated 25-OHD catabolism (phenytoin, phenobarbital).
- End-organ resistance to 1,25-dihydroxyvitamin D.

Hypomagnesemia: hypocalcemia caused by:
Decreased PTH secretion.
Inhibition of PTH effect on bone.
Pancreatitis, hyperphosphatemia, osteoblastic metastases: hypocalcemia is secondary to increased calcium deposits (bone, abdomen).
Pseudohypoparathyroidism (PHP): autosomal recessive disorder characterized by short stature, shortening of metacarpal bones, obesity, and mental retardation; the hypocalcemia is secondary to congenital end-organ resistance to PTH.
Idiopathic hypoparathyroidism, surgical removal of parathyroids (e.g., neck surgery).
"Hungry bones syndrome": rapid transfer of calcium from plasma into bones after removal of a parathyroid tumor.
Sepsis.
Massive blood transfusion (as a result of EDTA in blood).

HYPOCALCEMIA IN PEDIATRIC PATIENTS[79]

ICD-10CM # E83.51 Hypocalcemia

CAUSES OF HYPOCALCEMIA

Neonatal Hypocalcemia

Early neonatal hypocalcemia (first few days of life)

Maternal hyperparathyroidism.
Maternal diabetes mellitus.
Toxemia of pregnancy.
Sepsis.
SGA, IUGR, prematurity.
Asphyxia.
Transfusion (citrated blood products).
Congenital rubella.
Hypomagnesemia.
Respiratory or metabolic alkalosis.

Late neonatal hypocalcemia (fourth to tenth day of life)

Vitamin D deficiency: nutritional deficiency; VDR loss-of-function mutation; deficient 1α-hydroxylase activity.
Phosphate overload: excessive intake of evaporated/whole milk.
Nutritional calcium deficiency.
Hypomagnesemia.
Hypoalbuminemia (nephrotic syndrome).
Transfusion (citrated blood products).
Acute/chronic kidney insufficiency.
Diuretics (furosemide).
Organic acidemia.
Primary hypoparathyroidism: DiGeorge syndrome; familial hypoparathyroidism; pseudohypoparathyroidism; Kenny-Caffey syndrome; partial deletion of GCMB; retardation dysmorphism syndrome; Pearson mitochondriopathy; Kerns-Sayre mitochondriopathy; PTH gene defects; CaSR-activating gene mutation.

Hypocalcemia in Childhood

Parathyroid-related hypocalcemia

Primary hypoparathyroidism: DiGeorge syndrome; familial hypoparathyroidism; pseudohypoparathyroidism; Kenny-Caffey syndrome; Sanjad-Sakati syndrome; partial deletion of GCMB; retardation dysmorphism syndrome; Pearson mitochondropathy; Kerns-Sayre mitochondropathy; PTH gene defects; CaSR-activating gene mutation; Bartter syndrome type 5.
Secondary hypoparathyroidism: radiation; surgery; infiltration (hemochromatosis, thalassemia, Wilson disease).
Autoimmune polyglandular syndrome type 1.

Vitamin D–related hypocalcemia

Nutritional vitamin D deficiency.
Defective 1α-hydroxylase activity.
VDR loss-of-function mutation.

Nutritional calcium deficiencyHypomagnesemia

Hyperphosphatemia: kidney failure, rhabdomyolysis, tumor lysis

Hypoalbuminemia (nephrotic syndrome)

Medications: diuretics, chemotherapy, transfusion (citrated blood)

Organic acidemia (IVA, MMA, PPA)

CaSR, Calcium-sensing receptor; *GCMB,* glial cell missing homolog B (a parathyroid-specific transcription factor); *IUGR,* intrauterine growth retardation; *IVA,* isovaleric acidemia; *MMA,* methylmalonic acidemia; *PPA,* propionic acidemia; *PTH,* parathyroid hormone; *SGA,* small for gestational age; *VDR,* vitamin D receptor.

HYPOCAPNIA

ICD-10CM # R06.8 Hypoventilation

Hyperventilation.
Pneumonia, pneumonitis.
Fever, sepsis.
Medications (salicylates, beta-adrenergic agonists, progesterone, methylxanthines).
Pulmonary disease (asthma, interstitial fibrosis).
Pulmonary embolism.
Hepatic failure.
Metabolic acidosis.
High altitude.
CHF.
Pregnancy.
Pain.
CNS lesions.

HYPOGLYCEMIA

ICD-10CM #

E16.2	Hypoglycemia, unspecified
E10.65	Type 1 diabetes mellitus with hyperglycemia
E15	Nondiabetic hypoglycemic coma
K91.2	Postsurgical malabsorption, not elsewhere classified
E16.2	Hypoglycemia, unspecified

Oral hypoglycemics (therapeutic, factitious).
Exogenous insulin (therapeutic, factitious).
Postoperative gastric emptying (alimentary hyperinsulinism).
Severe malnutrition.
Liver disease.
Hypermetabolic state (sepsis).
Ketotic hypoglycemia.
Insulinoma.
Antibodies to endogenous insulin.
Hormone deficiencies (glucagon, growth hormone, hypoadrenalism).
Enzyme disorders in metabolism of glycogen, hexose, glycolysis, and Krebs cycle.
Idiopathic.

HYPOGLYCEMIA, IN INFANTS AND CHILDREN[53]

ICD-10CM # E16.2 Hypoglycemia, unspecified

CLASSIFICATION OF HYPOGLYCEMIA IN INFANTS AND CHILDREN

Neonatal Transient Hypoglycemia

Associated with Inadequate Substrate or Immature Enzyme Function in Otherwise Normal Neonates

Prematurity.
Small for gestational age.
Normal newborn.

Transient Neonatal Hyperinsulinism Also Present in

Infant of diabetic mother.
Discordant twin.
Birth asphyxia.
Infant of toxemic mother.

NEONATAL, INFANTILE, OR CHILDHOOD PERSISTENT HYPOGLYCEMIAS

Hormonal Disorders

Hyperinsulinism.
Recessive KATP channel HI.
Recessive HADH (hydroxyl acyl CoA dehydrogenase) mutation HI.
Recessive UCP2 (mitochondrial uncoupling protein 2) mutation HI.
Focal KATP channel HI.
Dominant KATP channel HI.
Dominant glucokinase HI.
Dominant glutamate dehydrogenase HI (hyperinsulinism/hyperammonemia syndrome).
Dominant mutation in HNF4A (hepatic nuclear factor 4 alpha) HI with MODY later in life.
Dominant mutation in SLC16A1 (the pyruvate transporter)-exercise-induced hypoglycemia.
Acquired islet adenoma.
Beckwith-Wiedemann syndrome.
Insulin administration (Munchausen syndrome by proxy).
Oral sulfonylurea drugs.
Congenital disorders of glycosylation.

Counter-Regulatory Hormone Deficiency

Panhypopituitarism.
Isolated growth hormone deficiency.
Addison disease.
Epinephrine deficiency.

Glycogenolysis and Gluconeogenesis Disorders

Glucose-6-phosphatase deficiency (GSD 1a).
Glucose-6-phosphate translocase deficiency (GSD 1b).
Amylo-1,6-glucosidase (debranching enzyme) deficiency (GSD 3).
Liver phosphorylase deficiency (GSD 6).

Phosphorylase kinase deficiency (GSD 9).
Glycogen synthetase deficiency (GSD 0).
Fructose-1,6-diphosphatase deficiency.
Pyruvate carboxylase deficiency.
Galactosemia.
Hereditary fructose intolerance.
Lipolysis Disorders
Fatty Acid Oxidation Disorders
Carnitine transporter deficiency (primary carnitine deficiency).
Carnitine palmitoyltransferase-1 deficiency.
Carnitine translocase deficiency.
Carnitine palmitoyltransferase-2 deficiency.
Secondary carnitine deficiencies.
Very long-, long-, medium-, short-chain acyl-CoA dehydrogenase deficiency.

OTHER ETIOLOGIES

Substrate-Limited
Ketotic hypoglycemia.
Poisoning: drugs.
Salicylates.
Alcohol.
Oral hypoglycemic agents.
Insulin.
Propranolol.
Pentamidine.
Quinine.
Disopyramide.
Ackee fruit (unripe): hypoglycin.
Vacor (rat poison).
Trimethoprim-sulfamethoxazole (with renal failure).
Liver Disease
Reye syndrome.
Hepatitis.
Cirrhosis.
Hepatoma.
Amino Acid and Organic Acid Disorders
Maple syrup urine disease.
Propionic acidemia.
Methylmalonic acidemia.
Tyrosinosis.
Glutaric aciduria.
3-Hydroxy-3-methylglutaric aciduria.
Systemic Disorders
Sepsis.
Carcinoma/sarcoma (secreting—insulin-like growth factor II).
Heart failure.
Malnutrition.
Malabsorption.
Anti-insulin receptor antibodies.
Anti-insulin antibodies.
Neonatal hyperviscosity.
Renal failure.
Diarrhea.
Burns.
Shock.
Postsurgical.
Pseudohypoglycemia (leukocytosis, polycythemia).
Excessive insulin therapy of insulin-dependent diabetes mellitus.
Factitious.
Nissen fundoplication (dumping syndrome).
Falciparum malaria.

GSD, Glycogen storage disease; *HI,* hyperinsulinemia; K_{ATP}, regulated potassium channel.

HYPOGONADISM

ICD-10CM #		
	E28.310	Symptomatic premature menopause
	E29.1	Testicular hypofunction
	E28.39	Other primary ovarian failure
	E23.6	Other disorders of pituitary gland

HYPERGONADOTROPIC HYPOGONADISM

Hormone resistance (androgen, LH insensitivity).
Gonadal defects (e.g., Klinefelter syndrome, myotonic dystrophy).
Drug-induced (e.g., spironolactone, cytotoxins).
Alcoholism, radiation-induced.
Mumps orchitis.
Anatomic defects, castration.

HYPOGONADOTROPIC HYPOGONADISM

Pituitary lesions (neoplasms, granulomas, infarction, hemochromatosis, vasculitis).
Drug-induced (e.g., glucocorticoids).
Hyperprolactinemia.
Genetic disorders (Laurence-Moon-Biedl syndrome, Prader-Willi).
Delayed puberty.
Other: chronic disease, nutritional deficiency, Kallmann syndrome, idiopathic isolated LH or FSH deficiency.

HYPOKALEMIA

ICD-10CM #		
	E87.6	Hypokalemia

Cellular shift (redistribution) and undetermined mechanisms.
Alkalosis (each 0.1 increase in pH decreases serum potassium by 0.4 to 0.6 mEq/L).
Insulin administration.
Vitamin B_{12} therapy for megaloblastic anemias, acute leukemias.
Hypokalemic periodic paralysis: rare familial disorder manifested by recurrent attacks of flaccid paralysis and hypokalemia.
Beta-adrenergic agonists (e.g., terbutaline), decongestants, bronchodilators, theophylline, caffeine.
Barium poisoning, toluene intoxication, verapamil intoxication, chloroquine intoxication.
Correction of digoxin intoxication with digoxin antibody fragments (Digibind).
Increased renal excretion.
Drugs:
- Diuretics, including carbonic anhydrase inhibitors (e.g., acetazolamide).
- Amphotericin B.
- High-dose sodium penicillin, nafcillin, ampicillin, or carbenicillin.
- Cisplatin.
- Aminoglycosides.
- Corticosteroids, mineralocorticoids.
- Foscarnet sodium.

RTA: distal (type 1) or proximal (type 2).
Diabetic ketoacidosis (DKA), ureteroenterostomy.
Magnesium deficiency.
Postobstruction diuresis, diuretic phase of ATN.
Osmotic diuresis (e.g., mannitol).
Bartter syndrome: hyperplasia of juxtaglomerular cells leading to increased renin and aldosterone, metabolic alkalosis, hypokalemia, muscle weakness, and tetany (seen in young adults).
Increased mineralocorticoid activity (primary or secondary aldosteronism), Cushing syndrome.
Chronic metabolic alkalosis from loss of gastric fluid (increased renal potassium secretion).
GI loss:
- Vomiting, nasogastric suction.
- Diarrhea.
- Laxative abuse.
- Villous adenoma.
- Fistulas.
- Inadequate dietary intake (e.g., anorexia nervosa).
- Cutaneous loss (excessive sweating).
- High dietary sodium intake, excessive use of licorice.

HYPOKALEMIA IN PEDIATRIC PATIENTS[79]

ICD-10CM #		
	E87.6	Hypokalemia

MOST RELEVANT CAUSES OF HYPOKALEMIA IN PEDIATRIC PATIENTS

Acute Redistribution of Potassium to the Intracellular Compartment
Metabolic alkalosis.
Insulin administration.
Hypokalemic periodic paralysis.
Prolonged Lack of Intake
Increased Renal Loss
Drugs: diuretics, antibiotics, aminoglycosides, penicillin, amphotericin B, capreomycin.
Metabolic acidosis and diabetic ketoacidosis.
Increased mineralocorticoid activity.
Cushing syndrome.
Congenital adrenal hyperplasia.
Primary or secondary hyperaldosteronism.
Primary tubulopathies.
Bartter syndrome.
Gitelman syndrome.
Liddle syndrome.
Types 1 and 2 renal tubular acidosis.
Epilepsy, ataxia, sensorineural deafness, and tubulopathy (EAST) syndrome.
Fanconi syndrome.
Increased Gastrointestinal Loss
Vomiting (hypertrophic pyloric stenosis).
Diarrhea.

HYPOMAGNESEMIA

ICD-10CM #		
	E83.40	Disorders of magnesium metabolism, unspecified
	E83.42	Hypomagnesemia

GASTROINTESTINAL AND NUTRITIONAL

Defective GI absorption (malabsorption).
Inadequate dietary intake (e.g., alcoholics).
Parenteral therapy without magnesium.
Chronic diarrhea, villous adenoma, prolonged nasogastric suction, fistulas (small bowel, biliary).

EXCESSIVE RENAL LOSSES

Diuretics.
RTA.
Diuretic phase of ATN.
Endocrine disturbances (DKA, hyperaldosteronism, hyperthyroidism, hyperparathyroidism), SIADH, Bartter syndrome, hypercalciuria, hypokalemia.
Cisplatin, alcohol, cyclosporine, digoxin, pentamidine, mannitol, amphotericin B, foscarnet, methotrexate.
Antibiotics (gentamicin, ticarcillin, carbenicillin).
Redistribution: hypoalbuminemia, cirrhosis, administration of insulin and glucose, theophylline, epinephrine, acute pancreatitis, cardiopulmonary bypass.
Miscellaneous: sweating, burns, prolonged exercise, lactation, "hungry-bones" syndrome.

HYPOMAGNESEMIA IN PEDIATRIC PATIENTS[79]

ICD-10CM # E83.42 Hypomagnesemia

MAIN CAUSES OF HYPOMAGNESEMIA IN CHILDREN

Primary Inherited Disorders

Familial hypomagnesemia with hypercalciuria and nephrocalcinosis.
Hypomagnesemia with secondary hypocalcemia.
Autosomal dominant hypomagnesemia.
Isolated autosomal recessive hypomagnesemia with normocalciuria.
Activating mutations of calcium-sensing receptor.
Gitelman syndrome.
Bartter syndrome.

Secondary Disorders

Decreased GI absorption:
- Malabsorptive syndromes.
- Vomiting and diarrhea.

Increased urinary excretion:
- Extracellular volume expansion.
- Polyuric states: obstructive uropathy, kidney transplant.

Drugs:
- Diuretics.
- Calcineurin antagonists.
- Others: cisplatinum, aminoglycosides, amphotericin B.
- Metabolic acidosis.

Miscellaneous: "hungry bone," low-birth-weight newborn, infant of diabetic mother.

HYPONATREMIA

ICD-10CM # E87.1 Hypo-osmolality and hyponatremia

Renal loss from renal disease, diuretics.
GI loss (diarrhea, vomiting, suction).
Hypertonic hyponatremia (e.g., increased serum osmolality from hyperglycemia).
Transcutaneous loss (extensive burns, excessive sweating).
Fluid sequestration (e.g., ascites).
Osmotic diuresis (e.g., mannitol, glucose).
Dilutional (psychogenic polydipsia, iatrogenic).
Syndrome of inappropriate antidiuretic hormone secretion.
Edema with water and sodium retention.
Artifact (e.g., severe hyperlipidemia).
Laboratory error.
Adrenal insufficiency.

HYPOPHOSPHATEMIA

ICD-10CM # E83.30 Disorder of phosphorus metabolism, unspecified
E83.31 Familial hypophosphatemia

Decreased intake (prolonged starvation [alcoholics], hyperalimentation, or IV infusion without phosphate).
Malabsorption.
Phosphate-binding antacids.
Renal loss:
- RTA.
- Fanconi syndrome, vitamin D–resistant rickets.
- ATN (diuretic phase).
- Hyperparathyroidism (primary or secondary).
- Familial hypophosphatemia.
- Hypokalemia, hypomagnesemia.
- Acute volume expansion.
- Glycosuria, idiopathic hypercalciuria.
- Acetazolamide.

Transcellular shift into cells:
- Alcohol withdrawal.
- DKA (recovery phase).
- Glucose-insulin or catecholamine infusion.
- Anabolic steroids.
- Total parenteral nutrition.
- Theophylline overdose.
- Severe hyperthermia; recovery from hypothermia.
- "Hungry bones" syndrome.

HYPOPHOSPHATEMIA IN PEDIATRIC PATIENTS[79]

ICD-10CM # E83.30 Disorder of phosphorus metabolism, unspecified

CAUSES OF HYPOPHOSPHATEMIA

Decreased Phosphate Intake

Starvation, inadequate phosphate intake, chronic diarrhea, chronic alcoholism.
Total parenteral nutrition with insufficient phosphate content.

Increased Loss of Phosphate

Increased renal phosphate excretion:
- Primary hyperparathyroidism.
- Secondary hyperparathyroidism: vitamin D deficiency or resistance (including 1α-hydroxylase deficiency, VDR mutations, VDDR); imatinib.
- Excess FGF-23 or phosphatonins: X-linked hypophosphatemia, AD hypophosphatemic rickets, tumor-induced osteomalacia, epidermal nevus, McCune-Albright syndrome.
- Fanconi syndrome, cystinosis, Wilson disease, Dent disease, Lowe syndrome, multiple myeloma, amyloidosis, heavy-metal toxicity, rewarming of hyperthermia, Na/Pi-IIa and Na/Pi-IIc mutation (HHRH).
- PTHrP-dependent hypercalcemia of malignancy.
- Hypomagnesemia.

Decreased intestinal absorption:
- Vitamin D deficiency or resistance (VDDR I and II).
- Malabsorption.

Increased intestinal loss:
- Phosphate binding antacids used in treating peptic ulcers.

Increased loss from other routes:
- Skin: severe burns.
- Vomiting.

Phosphate Shifting from Extracellular Compartment to Cells and Bones

Diabetic ketoacidosis.
Alcohol intoxication.
Acute respiratory alkalosis, salicylate intoxication, gram-negative sepsis, toxic shock syndrome, acute gout.
Refeeding syndromes from starvation, anorexia nervosa, hepatic failure: acute intravenous glucose, fructose, glycerol.
Rapid cellular proliferation: intensive erythropoietin therapy, GM-CSF therapy, leukemic blast crisis.
Recovery from hypothermia.
Heat stroke.
Post parathyroidectomy; "hungry bone" disease: osteoblastic metastases, antiresorptive treatment of severe Paget disease.
Catecholamine (albuterol, dopamine, terbutaline, epinephrine).
Thyrotoxic periodic paralysis.
Hypocalcemic periodic paralysis.

Miscellaneous

Hyperaldosteronism.
Oncogenic hypophosphatemia.
Post kidney transplantation.
Post partial hepatectomy.
High-dose corticosteroids, estrogens.
Medications: ifosfamide, toluene, calcitonin, bisphosphonate, tenofovir, paraquat, cisplatin, acetazolamide and other diuretics.
Post obstructive diuresis.

AD, Autosomal dominant; *FGF-23,* fibroblast growth factor 23; *GM-CSF,* granulocyte-macrophage colony-stimulating factor; *HHRH,* hereditary hypophosphatemic rickets with hypercalciuria; *Na/Pi-II,* type II sodium-dependent phosphate cotransporter; *PTHrP,* parathyroid hormone–related peptide; *VDR,* vitamin D receptor; *VDDR,* vitamin D–dependent rickets.

HYPOPIGMENTATION

ICD-10CM # L81.9 Disorder of pigmentation, unspecified

Vitiligo.
Tinea versicolor.
Atopic dermatitis.
Chemical leukoderma.
Idiopathic hypomelanosis.
Sarcoidosis.
SLE.

Scleroderma.
Oculocutaneous albinism.
Phenylketonuria.
Nevoid hypopigmentation.

HYPOTENSION, POSTURAL

ICD-10CM # I95.89 Other hypotension

Antihypertensive medications (especially a-blockers, diuretics, ACE inhibitors).
Volume depletion (hemorrhage, dehydration).
Impaired cardiac output (constrictive pericarditis, aortic stenosis).
Peripheral autonomic dysfunction (DM, Guillain-Barré).
Idiopathic orthostatic hypotension.
Central autonomic dysfunction (Shy-Drager syndrome).
Peripheral venous disease.
Adrenal insufficiency.

HYPOTHYROIDISM, CONGENITAL[53]

ICD-10CM # E03.0 Congenital hypothyroidism with diffuse goiter
E03.1 Congenital hypothyroidism without goiter

ETIOLOGIC CLASSIFICATION OF CONGENITAL HYPOTHYROIDISM

Primary Hypothyroidism

Defect of fetal thyroid development (dysgenesis):
  Aplasia.
  Hypoplasia.
  Ectopia.
Defect in thyroid hormone synthesis (dyshormonogenesis):
  Iodide transport defect: mutation in thyroglobulin gene.
  Thyroid organification, or coupling defect: mutation in thyroid peroxidase gene.
  Defects in H_2O_2 generation: mutations in DUOXA2 maturation factor or *DUOX2* gene.
  Thyroglobulin synthesis defect: mutation in thyroglobulin gene.
  Deiodination defect: mutation in *DEHAL1* gene.
TSH unresponsiveness:
  $G_s\alpha$ mutation (e.g., type 1A pseudohypothyroidism).
  Mutation in TSH receptor.
Defect in thyroid hormone transport: mutation in monocarboxylate transporter 8 *(MCT8)* gene.
Iodine deficiency (endemic goiter).
Maternal antibodies: thyrotropin receptor–blocking antibody (TRBAb, also termed *thyrotropin-binding inhibitor immunoglobulin*).
Maternal medications:
  Iodides, amiodarone.
  Propylthiouracil, methimazole.
  Radioiodine.

CENTRAL (HYPOPITUITARY) HYPOTHYROIDISM

PIT-1 mutations:
  Deficiency of thyroid-stimulating hormone (TSH).
  Deficiency of growth hormone.
  Deficiency of prolactin.
PROP-1 mutations:
  Deficiency of TSH.
  Deficiency of growth hormone.
  Deficiency of prolactin.
  Deficiency of luteinizing hormone.
  Deficiency of follicle-stimulating hormone.
  ±Deficiency of adrenocorticotropic hormone.
TSH deficiency: mutation in TSH β subunit gene (manifests as primary hypothyroidism with elevated TSH level).
Multiple pituitary deficiencies (e.g., craniopharyngioma).
Thyroid-releasing hormone (TRH) deficiency:
  Isolated.
  Multiple hypothalamic deficiencies (e.g., septooptic dysplasia).
TRH unresponsiveness.
Mutations in TRH receptor.

HYPOTONIA, INFANTILE, DIFFERENTIAL DIAGNOSIS[53]

ICD-10CM # H44.40 Unspecified hypotony of eye

Cerebral hypotonia:
  Benign congenital hypotonia.
  Chromosome disorders.
  Prader-Willi syndrome.
  Trisomy.
  Chronic nonprogressive encephalopathy.
  Cerebral malformation.
  Perinatal distress.
  Postnatal disorders.
  Peroxisomal disorders.
  Cerebrohepatorenal syndrome (Zellweger syndrome).
  Neonatal adrenoleukodystrophy.
  Other genetic defects.
  Familial dysautonomia.
  Oculocerebrorenal syndrome (Lowe syndrome).
  Other metabolic defects.
  Acid maltase deficiency (see "Metabolic Myopathies").
  Infantile GM, gangliosidosis.
Spinal cord disorders.
Spinal muscular atrophies:
  Acute infantile.
  Autosomal dominant.
  Autosomal recessive.
  Cytochrome-*c* oxidase deficiency.
  X-linked.
Chronic infantile:
  Autosomal dominant.
  Autosomal recessive.
  Congenital cervical spinal muscular atrophy.
  Infantile neuronal degeneration.
  Neurogenic arthrogryposis.
Polyneuropathies:
  Congenital hypomyelinating neuropathy.
  Giant axonal neuropathy.
  Hereditary motor-sensory neuropathies.
Disorders of neuromuscular transmission:
  Familial infantile myasthenia.
  Infantile botulism.
  Transitory myasthenia gravis.
  Fiber-type disproportion myopathies.
  Central core disease.
  Congenital fiber-type disproportion myopathy.
  Myotubular (centronuclear) myopathy.
  Acute.
  Chronic.
  Nemaline (rod) myopathy.
  Autosomal dominant.
  Autosomal recessive.
Metabolic myopathies:
  Acid maltase deficiency.
  Cytochrome-*c* oxidase deficiency.
Muscular dystrophies:
  Bethlem myopathy.
  Congenital dystrophinopathy.
  Congenital muscular dystrophy.
  Merosin deficiency, primary.
  Merosin deficiency, secondary.
  Merosin positive.
  Congenital myotonic dystrophy.

HYPOTONIC POLYURIA[79]

ICD-10CM # Varies with specific diagnosis

CAUSES OF HYPOTONIC POLYURIA

Central (Neurogenic) Diabetes Insipidus

Congenital (congenital malformations, autosomal dominant, arginine vasopressin [AVP] neurophysin gene mutations).
Drug- or toxin-induced (ethanol, diphenylhydantoin, snake venom).
Granulomatous (histiocytosis, sarcoidosis).
Neoplastic (craniopharyngioma, germinoma, lymphoma, leukemia, meningioma, pituitary tumor; metastases).
Infectious (meningitis, tuberculosis, encephalitis).
Inflammatory, autoimmune (lymphocytic infundibuloneurohypophysitis).
Trauma (neurosurgery, deceleration injury).
Vascular (cerebral hemorrhage or infarction, brain death).
Idiopathic.

Osmoreceptor Dysfunction

Granulomatous (histiocytosis, sarcoidosis).
Neoplastic (craniopharyngioma, pinealoma, meningioma, metastases).
Vascular (anterior communicating artery aneurysm or ligation, intrahypothalamic hemorrhage).
Other (hydrocephalus, ventricular or suprasellar cyst, trauma, degenerative diseases).
Idiopathic.

Increased AVP Metabolism

Pregnancy

Nephrogenic Diabetes Insipidus

Congenital (X-linked recessive, AVP V2 receptor gene mutations, autosomal recessive or dominant, aquaporin-2 water channel gene mutations).
Drug-induced (demeclocycline, lithium, cisplatin, methoxyflurane).
Hypercalcemia.
Hypokalemia.
Infiltrating lesions (sarcoidosis, amyloidosis).
Vascular (sickle cell anemia).
Mechanical (polycystic kidney disease, bilateral ureteral obstruction).

Solute diuresis (glucose, mannitol, sodium, radiocontrast dyes).
Idiopathic.
Primary Polydipsia
Psychogenic (schizophrenia, obsessive-compulsive behaviors).
Dipsogenic (downward resetting of thirst threshold, idiopathic or similar lesions, as with central DI).

HYPOVOLEMIA[79]

ICD-10CM # Varies with specific diagnosis

CAUSES OF ABSOLUTE AND RELATIVE HYPOVOLEMIA

Absolute
Extrarenal
GI fluid loss.
Bleeding.
Skin fluid loss.
Respiratory fluid loss.
Extracorporeal ultrafiltration.
Renal
Diuretics.
Obstructive uropathy/postobstructive diuresis.
Hormone deficiency.
Hypoaldosteronism.
Adrenal insufficiency.
Na+ wasting tubulopathies.
Genetic.
Acquired tubulointerstitial disease.
Relative
Extrarenal
Edematous states.
Heart failure.
Cirrhosis.
Generalized vasodilation.
Sepsis.
Drugs.
Pregnancy.
Third-space loss.
Renal
Severe nephrotic syndrome.

HYPOVOLEMIC SHOCK, PEDIATRIC POPULATION[29]

ICD-10CM # R57.1 Hypovolemic shock
R57.8 Other shock

ETIOLOGIES OF HYPOVOLEMIC SHOCK

Whole blood loss.
Absolute loss: hemorrhage.
External bleeding.
Internal bleeding:
GI.
Intraabdominal (spleen, liver).
Major vessel injury.
Intracranial (in infants).
Fractures.
Relative loss:
Pharmacologic (barbiturates, vasodilators).
Positive pressure ventilation.
Spinal cord injury.
Sepsis.
Anaphylaxis.
Plasma loss.
Burns.
Capillary leak syndromes:
Inflammation, sepsis.
Anaphylaxis.
Protein-losing syndromes.
Fluid and electrolyte loss.
Vomiting and diarrhea.
Excessive diuretic use.
Endocrine:
Adrenal insufficiency.
Diabetes insipidus.
Diabetes mellitus.

HYPOXEMIA AND HYPERCAPNIC RESPIRATORY FAILURE[69]

ICD-10CM # Varies with specific diagnosis

COMMON CAUSES OF HYPOXEMIC AND HYPERCAPNIC RESPIRATORY FAILURE

Brain
Bulbar poliomyelitis.
Central alveolar hypoventilation.
Cerebrovascular accident.
Cerebral malignancy.
Drug overdose (e.g., narcotic, sedative/hypnotic).
Elevated intracranial pressure.
Encephalitis and meningitis.
Pontine herniation.
Postoperative anesthetic depression.
Spinal Cord
Amyotrophic lateral sclerosis.
Cervical cordotomy.
Guillain-Barré syndrome.
Poliomyelitis.
Spinal cord trauma.
Neuromuscular System
Acute intermittent porphyria.
Botulism.
Cholinergic crisis.
Curariform drugs.
Electrolyte disorders (e.g., hypophosphatemia, hypomagnesemia).
Hypokalemic periodic paralysis.
Multiple sclerosis.
Myasthenia gravis.
Myxedema.
Neuromuscular blocking antibiotics (e.g., polymyxin, streptomycin).
Organophosphate insecticides.
Peripheral neuritis.
Polymyositis.
Respiratory muscle fatigue—critical illness polyneuropathy/polymyopathy.
Tetanus.
Upper Airway
Epiglottitis and laryngotracheitis.
Large tonsils and adenoids.
Obstructive sleep apnea.
Postintubation laryngeal edema.
Tracheal obstruction.
Vocal cord paralysis.
Thorax and Pleura
Chest wall burn with eschar formation.
Chest wall trauma—flail chest.
Kyphoscoliosis.
Massive abdominal distention.
Massive obesity.
Muscular dystrophy.
Large pleural effusion/pleural fibrosis.
Pneumothorax.
Rheumatoid spondylitis.
Thoracoplasty.
Cardiovascular System
Cardiogenic pulmonary edema.
Left ventricular failure.
Mitral stenosis.
Biventricular failure.
Fat embolism.
Snake bite.
Uremia.
Volume overload.
Pulmonary veno-occlusive disease.
Lower Airway and Alveoli
Acute respiratory distress syndrome (ARDS).
Aspiration.
Asthma.
Atelectasis.
Bronchiectasis.
Bronchiolitis.
Chronic obstructive pulmonary disease.
Cystic fibrosis.
Interstitial lung disease.
Massive bilateral pneumonia.
Near-drowning.
Pancreatitis.
Pulmonary contusion.
Radiation lung injury.
Sepsis.
Smoke inhalation.
Surgical resection of lung parenchym.

ILIAC FOSSA PAIN, LEFT SIDED[86]

ICD-10CM # M25.5 Pain in joint

GASTROINTESTINAL CAUSES OF ACUTE LEFT ILIAC FOSSA PAIN

Nonspecific left iliac fossa pain including constipation.
Acute gastroenteritis.
Acute diverticulitis.
Colonic carcinoma.
Colonic ischemia.
Localized small bowel perforation.

ILIAC FOSSA PAIN, RIGHT SIDED[86]

ICD-10CM # M25.5 Pain in joint

DIFFERENTIAL DIAGNOSIS OF RIGHT ILIAC FOSSA PAIN

Gastrointestinal Causes
Nonspecific right iliac fossa pain.
Acute appendicitis.
Mesenteric adenitis.
Terminal ileitis.
Acute inflammation of Meckel diverticulum.
Crohn disease of the terminal ileum.

Solute diuresis (glucose, mannitol, sodium, radiocontrast dyes).
Idiopathic.
Primary Polydipsia
Psychogenic (schizophrenia, obsessive-compulsive behaviors).
Dipsogenic (downward resetting of thirst threshold, idiopathic or similar lesions, as with central DI).

HYPOVOLEMIA[79]

ICD-10CM # Varies with specific diagnosis

CAUSES OF ABSOLUTE AND RELATIVE HYPOVOLEMIA

Absolute
Extrarenal
GI fluid loss.
Bleeding.
Skin fluid loss.
Respiratory fluid loss.
Extracorporeal ultrafiltration.
Renal
Diuretics.
Obstructive uropathy/postobstructive diuresis.
Hormone deficiency.
Hypoaldosteronism.
Adrenal insufficiency.
Na+ wasting tubulopathies.
Genetic.
Acquired tubulointerstitial disease.
Relative
Extrarenal
Edematous states.
Heart failure.
Cirrhosis.
Generalized vasodilation.
Sepsis.
Drugs.
Pregnancy.
Third-space loss.
Renal
Severe nephrotic syndrome.

HYPOVOLEMIC SHOCK, PEDIATRIC POPULATION[29]

ICD-10CM # R57.1 Hypovolemic shock
R57.8 Other shock

ETIOLOGIES OF HYPOVOLEMIC SHOCK

Whole blood loss.
Absolute loss: hemorrhage.
External bleeding.
Internal bleeding:
GI.
Intraabdominal (spleen, liver).
Major vessel injury.
Intracranial (in infants).
Fractures.
Relative loss:
Pharmacologic (barbiturates, vasodilators).
Positive pressure ventilation.
Spinal cord injury.
Sepsis.
Anaphylaxis.
Plasma loss.
Burns.
Capillary leak syndromes:
Inflammation, sepsis.
Anaphylaxis.
Protein-losing syndromes.
Fluid and electrolyte loss.
Vomiting and diarrhea.
Excessive diuretic use.
Endocrine:
Adrenal insufficiency.
Diabetes insipidus.
Diabetes mellitus.

HYPOXEMIA AND HYPERCAPNIC RESPIRATORY FAILURE[69]

ICD-10CM # Varies with specific diagnosis

COMMON CAUSES OF HYPOXEMIC AND HYPERCAPNIC RESPIRATORY FAILURE

Brain
Bulbar poliomyelitis.
Central alveolar hypoventilation.
Cerebrovascular accident.
Cerebral malignancy.
Drug overdose (e.g., narcotic, sedative/hypnotic).
Elevated intracranial pressure.
Encephalitis and meningitis.
Pontine herniation.
Postoperative anesthetic depression.
Spinal Cord
Amyotrophic lateral sclerosis.
Cervical cordotomy.
Guillain-Barré syndrome.
Poliomyelitis.
Spinal cord trauma.
Neuromuscular System
Acute intermittent porphyria.
Botulism.
Cholinergic crisis.
Curariform drugs.
Electrolyte disorders (e.g., hypophosphatemia, hypomagnesemia).
Hypokalemic periodic paralysis.
Multiple sclerosis.
Myasthenia gravis.
Myxedema.
Neuromuscular blocking antibiotics (e.g., polymyxin, streptomycin).
Organophosphate insecticides.
Peripheral neuritis.
Polymyositis.
Respiratory muscle fatigue—critical illness polyneuropathy/polymyopathy.
Tetanus.
Upper Airway
Epiglottitis and laryngotracheitis.
Large tonsils and adenoids.
Obstructive sleep apnea.
Postintubation laryngeal edema.
Tracheal obstruction.
Vocal cord paralysis.
Thorax and Pleura
Chest wall burn with eschar formation.
Chest wall trauma—flail chest.
Kyphoscoliosis.
Massive abdominal distention.
Massive obesity.
Muscular dystrophy.
Large pleural effusion/pleural fibrosis.
Pneumothorax.
Rheumatoid spondylitis.
Thoracoplasty.
Cardiovascular System
Cardiogenic pulmonary edema.
Left ventricular failure.
Mitral stenosis.
Biventricular failure.
Fat embolism.
Snake bite.
Uremia.
Volume overload.
Pulmonary veno-occlusive disease.
Lower Airway and Alveoli
Acute respiratory distress syndrome (ARDS).
Aspiration.
Asthma.
Atelectasis.
Bronchiectasis.
Bronchiolitis.
Chronic obstructive pulmonary disease.
Cystic fibrosis.
Interstitial lung disease.
Massive bilateral pneumonia.
Near-drowning.
Pancreatitis.
Pulmonary contusion.
Radiation lung injury.
Sepsis.
Smoke inhalation.
Surgical resection of lung parenchym.

ILIAC FOSSA PAIN, LEFT SIDED[86]

ICD-10CM # M25.5 Pain in joint

GASTROINTESTINAL CAUSES OF ACUTE LEFT ILIAC FOSSA PAIN

Nonspecific left iliac fossa pain including constipation.
Acute gastroenteritis.
Acute diverticulitis.
Colonic carcinoma.
Colonic ischemia.
Localized small bowel perforation.

ILIAC FOSSA PAIN, RIGHT SIDED[86]

ICD-10CM # M25.5 Pain in joint

DIFFERENTIAL DIAGNOSIS OF RIGHT ILIAC FOSSA PAIN

Gastrointestinal Causes
Nonspecific right iliac fossa pain.
Acute appendicitis.
Mesenteric adenitis.
Terminal ileitis.
Acute inflammation of Meckel diverticulum.
Crohn disease of the terminal ileum.

Cecal carcinoma.
Inflammatory cecal lesion (e.g., diverticulitis in a solitary cecal diverticulum).
Inflammatory lesion of the terminal ileum (e.g., foreign body perforation).
Non-Gastrointestinal Causes
Ruptured ovarian follicle (mittelschmerz).
Acute salpingitis (pelvic inflammatory disease).
Rupture/torsion or hemorrhage of an ovarian cyst.
Endometriosis.
Ectopic pregnancy.
Urinary tract infection.

IMMUNODEFICIENCY, CONGENITAL (PRIMARY)

ICD-10CM #		
	D80.0	Hereditary hyopgammaglobulinemia
	D80.1	Nonfamilial hypogammaglobulinemia
	D80.2	Selective deficiency of IgA
	D80.3	Selective deficiency of IgG
	D80.4	Selective deficiency of IgM

CONGENITAL (PRIMARY) CAUSES OF IMMUNODEFICIENCY

T-lymphocyte Deficiencies
DiGeorge syndrome (thymic aplasia with reduced CD4 and CD3 cells).
Purine nucleoside phosphorylase deficiency (marked T-cell depletion).
B-lymphocyte Deficiencies
Bruton X-linked agammaglobulinemia (absence of B cells, plasma cells, and antibody).
Selective immunoglobulin G (IgG) subclass deficiencies.
Selective IgA deficiency.
Hyper-IgM immunodeficiency (elevated IgM but reduced IgG and IgA).
Mixed T- and B-lymphocyte Deficiencies
Common variable immunodeficiency (leads to various B-cell activation or differentiation defects and gradual deterioration of T-cell number and function).
Severe combined immunodeficiency (severe reduction in IgG and absence of T cells).
Wiskott-Aldrich syndrome (decreased T-cell number and function, low IgM, occasionally low IgG).
Ataxia-telangiectasia (decreased T-cell number and function; IgA, IgE, IgG_2, and IgG_4 deficiency).
Disorders of Complement
C3 deficiency (congenital absence of C3 or consumption of C3 due to deficiency of C3b inactivator).
Phagocyte Defects
Chronic granulomatous disease (defect in nicotinamide adenine dinucleotide phosphate oxidase in phagocytic cells).
Chédiak-Higashi syndrome (impaired microbicidal activity of phagocytes).
Kostmann syndrome, Shwachman-Diamond syndrome, cyclic neutropenia (low neutrophil count).

IMPAIRED CONSCIOUSNESS AND COMA[84]

ICD-10CM #		
	R40.20	Unspecified coma

INFECTIOUS OR INFLAMMATORY

Infectious
Bacterial meningitis.
Viral encephalitis.
Rickettsial infection.
Protozoan infection.
Helminth infestation.
Inflammatory
Sepsis-associated encephalopathy.
Vasculitis, collagen vascular disorders.
Demyelination.
Acute disseminated encephalomyelitis.
Multiple sclerosis.

STRUCTURAL

Traumatic
Concussion.
Cerebral contusion.
Epidural hematoma or effusion.
Intracerebral hematoma.
Diffuse axonal injury.
Abusive head trauma.
Neoplasms
Vascular Disease
Cerebral infarction:
- Thrombosis.
- Embolism.
- Venous sinus thrombosis.

Cerebral hemorrhage:
- Subarachnoid hemorrhage.
- Arteriovenous malformation.
- Aneurysm.

Congenital abnormality or dysplasia of vascular supply
Trauma to carotid or vertebral arteries in the neck
Focal Infection
Abscess.
Cerebritis.
Hydrocephalus

METABOLIC, NUTRITIONAL, OR TOXIC

Hypoxic-Ischemic Encephalopathy
Shock.
Cardiac or pulmonary failure.
Near-drowning.
Carbon monoxide poisoning.
Cyanide poisoning.
Strangulation.
Metabolic Disorders
Sarcoidosis.
Hypoglycemia.
Fluid and electrolyte imbalance.
Endocrine disorders:
- With acidosis:
  - Diabetic ketoacidosis.
  - Aminoacidemias.
  - Organic acidemias.
- With hyperammonemia:
  - Hepatic encephalopathy.
  - Urea cycle disorders.
  - Disorders of fatty acid metabolism.
  - Reye syndrome.
  - Valproic acid encephalopathy.

Uremia.
Porphyria.
Mitochondrial disorders.
Leigh syndrome.
Nutritional
Thiamine deficiency.
Niacin or nicotinic acid deficiency.
Pyridoxine dependency.
Folate and B_{12} deficiency.
Exogenous Toxins and Poisons
Alcohol intoxication.
Over-the-counter medications.
Prescription medications (oral and ophthalmic).
Herbal treatments.
Heavy-metal poisoning.
Mushroom and plant intoxication.
Illegal drugs.
Industrial agents.
Hypertensive Encephalopathy
Burn Encephalopathy

IMPOTENCE[63]

ICD-10CM #		
	F52.21	Male erectile disorder
	F52.8	Other sexual dysfunction not due to a substance or known physiological condition
	N52.9	Male erectile dysfunction, unspecified

Psychogenic.
Endocrine: hyperprolactinemia, DM, Cushing syndrome, hypothyroidism or hyperthyroidism, abnormality of hypothalamic-pituitary-testicular axis.
Vascular: arterial insufficiency, venous leakage, AV malformation, local trauma.
Medications.
Neurogenic: autonomic or sensory neuropathy, spinal cord trauma or tumor, CVA, multiple sclerosis, temporal lobe epilepsy.
Systemic illness: renal failure, COPD, cirrhosis of liver, myotonic dystrophy.
Peyronie disease.
Prostatectomy.

INCONTINENCE, FECAL[86]

ICD-10CM #		
	R15.9	Full incontinence of feces

NORMAL SPHINCTER

Diarrhea.
Anorectal conditions:
- Rectal carcinoma.
- Inflammatory bowel disease.
- Hemorrhoids.
- Mucosal prolapse.
- Fissure-in-ano.
- Abnormal rectal sensation.

ABNORMAL SPHINCTER

Congenital abnormalities.
Anal sepsis.
Neurologic conditions.
Rectal prolapse.
Sphincter trauma.
Neurogenic (idiopathic) incontinence.

INFECTIOUS DIARRHEA IN TROPICS[26]

ICD-10CM # R19.7 Diarrhea, unspecified

CAUSES OF INFECTIOUS DIARRHEA IN THE TROPICS

Bacteria
Aeromonas hydrophila.
Arcobacter butzleri.
Bacteroides fragilis, enterotoxigenic.
Campylobacter jejuni.
Escherichia coli: enterotoxigenic, enteroaggregative, enteroinvasive, enterohemorrhagic.
Laribacter hongkongensis.
Plesiomonas shigelloides.
Salmonella, non-typhoidal.
Shigella species: *S. dysenteriae, S. flexneri, S. sonnei, S. boydii.*
Vibrio cholerae 01, 0139, non-01 non-0139.
Vibrio parahaemolyticus.
Yersinia enterocolitica.
Helminths
Paracapillaria philippinensis.
Fasciolopsis buski.
Heterophyiasis (Metagonimus yokogawai, Haplorchis taichui).
Schistosoma mansoni.
Strongyloides stercoralis.
Protozoa
Blastocystis hominis.
Cryptosporidium parvum.
Cyclospora cayetanensis.
Encephalitozoon intestinalis.
Enterocytozoon bieneusi.
Giardia lamblia.
Isospora belli.
Leishmania donovani.
Viruses
Astroviruses.
Caliciviruses: norovirus and sapovirus.
Enteric adenoviruses.
HIV.
Picornaviruses.
Rotavirus.

INFERTILITY, FEMALE[32]

ICD-10CM # N97.9 Female infertility, unspecified

FALLOPIAN TUBE PATHOLOGY

PID or puerperal infection.
Congenital anomalies.
Endometriosis.
Secondary to past peritonitis of nongenital origin.
Amenorrhea and anovulation.
Minor anovulatory disturbances.

CERVICAL AND UTERINE FACTORS

Leiomyomas and polyps.
Uterine anomalies.
Intrauterine synechiae (Asherman syndrome).
Destroyed endocervical glands (postsurgery or postinfection).

VAGINAL FACTORS

Congenital absence of vagina.
Imperforate hymen.
Vaginismus.
Vaginitis.

IMMUNOLOGIC FACTORS

Sperm-immobilizing antibodies.
Sperm-agglutinating antibodies.

NUTRITIONAL AND METABOLIC FACTORS

Thyroid disorders.
DM.
Severe nutritional disturbances.

INFERTILITY, MALE[32]

ICD-10CM # N46.9 Male infertility, unspecified

DECREASED PRODUCTION OF SPERMATOZOA

Varicocele.
Testicular failure.
Endocrine disorders.
Cryptorchidism.
Stress, smoking, caffeine, nicotine, recreational drugs.

DUCTAL OBSTRUCTION

Epididymal (postinfection).
Congenital absence of vas deferens.
Ejaculatory duct (postinfection).
Postvasectomy.

INABILITY TO DELIVER SPERM INTO VAGINA

Ejaculatory disturbances.
Hypospadias.
Sexual problems (i.e., impotence), medical or psychological.

ABNORMAL SEMEN

Infection.
Abnormal volume.
Abnormal viscosity.
Abnormal sperm motion.

IMMUNOLOGIC FACTORS

Sperm-immobilizing antibodies.
Sperm-agglutinating antibodies.

INSOMNIA[76]

ICD-10CM #	780.51	Insomnia with sleep apnea
	G47.00	Insomnia, unspecified
	F51.01	Primary insomnia
	F51.03	Paradoxical insomnia
	F51.09	Other insomnia not due to a substance or known physiological condition

Anxiety disorder, psychophysiologic insomnia.
Depression.
Drugs (e.g., caffeine, amphetamines, cocaine), hypnotic-dependent sleep disorder.
Pain, fibromyalgia.
Inadequate sleep hygiene.
Restless leg syndrome.
Obstructive sleep apnea.
Sleep bruxism.
Medical illness (e.g., GERD, sleep-related asthma, parkinsonism and movement disorders).
Narcolepsy.
Other: periodic leg movement of sleep, central sleep apnea, REM behavioral disorder.

INTESTINAL PSEUDOOBSTRUCTION[82,54]

ICD-10CM #	K56.0	Paralytic ileus
	K56.9	Ileus, unspecified
	K59.9	Functional intestinal disorder, unspecified

"PRIMARY" (IDIOPATHIC INTESTINAL PSEUDOOBSTRUCTION)

Hollow visceral myopathy:
  Familial.
  Sporadic.
Neuropathic:
  Abnormal myenteric plexus.
  Normal myenteric plexus.

SECONDARY

Scleroderma.
Myxedema.
Amyloidosis.
Muscular dystrophy.
Hypokalemia.
Chronic renal failure.
DM.
Drug toxicity caused by:
  Anticholinergics.
  Opiate narcotics.
Ogilvie syndrome.

Causes of Secondary Chronic Intestinal Pseudoobstruction in Children

Autoimmune
Autoimmune myositis.
Autoimmune ganglionitis.
Scleroderma.
Endocrine
Diabetes mellitus.
Hypoparathyroidism.
Hypothyroidism.
Gastrointestinal
Celiac disease.
Eosinophilic gastroenteritis.
Inflammatory bowel disease.
Hematology/oncology
Multiple myeloma.
Paraneoplastic syndromes.
Pheochromocytoma.
Sickle cell disease.
Infection
Chagas disease.
Cytomegalovirus.
Epstein-Barr virus.
Herpes zoster.
JC virus.
Kawasaki disease.
Postviral neuropathy.
Medications and toxins
Chemotherapy.
Cyclopentolate and phenylephrine eye drops.
Diltiazem and nifedipine.
Fetal alcohol syndrome.
Jellyfish envenomation.

Causes of Secondary Chronic Intestinal Pseudoobstruction in Children—Cont'd

Opioid medications.
Postanesthesia.
Radiation injury.
Mitochondrial disorders
Mitochondrial neurogastrointestinal encephalomyopathy.
Musculoskeletal disorders
Ehlers-Danlos syndrome.
Myotonic dystrophy.
Duchenne muscular dystrophy.
Rheumatology
Amyloidosis.
Dermatomyositis.
Polymyositis.
Systemic lupus erythematous.

From Wyllie R, Hyams JS, Kay M, editors: *Pediatric gastrointestinal and liver disease,* 5th ed, Elsevier, 2016, Philadelphia, Box. 44.3, p. 548.

INTRAABDOMINAL MASS LESION, NEONATAL[36]

ICD-10CM # R19.00 Intraabdominal and pelvic swelling, mass and lump, unspecified site

CAUSES OF A NEONATAL INTRAABDOMINAL MASS LESION

Complicated meconium ileus.
Dilated bowel proximal to an obstruction.
Mesenteric or duplication cyst.
Abscess.
GU causes:
- Hydronephrosis.
- Renal cystic disease.
- Mesoblastic nephroma.
- Wilms tumor.
- Adrenal hemorrhage.
- Neuroblastoma.
- Retroperitoneal teratoma.
- Ovarian cyst.
- Hydrometrocolpos.

Hemangioendothelioma.
Hepatoblastoma.
Choledochal, hepatic, or splenic cysts.

INTRACEREBRAL HEMORRHAGE, NONHYPERTENSIVE CAUSES

ICD-10CM # I61.9 Nontraumatic intracerebral hemorrhage, unspecified

Trauma.
Anticoagulation.
Intracranial tumors.
Vascular malformations.
Bleeding disorders.
Vasculitides (e.g., polyarteritis nodosa, granulomatous angiitis).
Cocaine and other sympathomimetic agents.
Cerebral amyloid angiopathy.

INTRACRANIAL LESION

ICD-10CM # G93.89 Other specified disorders of brain

Tumor (primary or metastatic).
Abscess.
Stroke.
Intracranial hemorrhage.
Angioma.
Multiple sclerosis (initial single lesion).
Granuloma.
Herpes encephalitis.
Artifact.

INTRAOCULAR NEOPLASM

ICD-10CM # C69.9 Malignant disorder of eye, unspecified

MALIGNANT

Retinoblastoma.
Melanoma.
Reticulum cell sarcoma.
Metastatic tumor.

BENIGN

Melanocytic nevus.
Hemangioma.
Reactive lymphoid hyperplasia.

IRON METABOLISM DISORDERS[5]

ICD-10CM # E83.10 Disorder of iron metabolism, unspecified

IRON DEFICIENCY

Deficient Iron Intake
Diet of low bioavailability.
Increased physiological requirements due to rapid growth in early childhood and in adolescence.
Blood loss.
Physiological (e.g., menstruation).
Pathological (e.g., GI).
Malabsorption of Iron
Reduced or absent gastric acid secretion (e.g., after partial or total gastrectomy or with atrophic gastritis).
Reduced duodenal absorption (e.g., in coeliac disease).
Bypass of stomach and duodenum (bariatric surgery).
Rare, inherited iron-refractory iron deficiency anemia (e.g., deficiency of TMPRSS6 [transmembrane protease, serine 6], also known as matriptase-2).
Redistribution of Iron
Macrophage iron accumulation in reticuloendothelial system in inflammatory, infectious, or malignant diseases (anemia of chronic disease, also known as anemia of inflammation).
Macrophage iron accumulation within the lungs in idiopathic pulmonary hemosiderosis.
Iron Overload
Due to Increased Iron Absorption
Hereditary hemochromatosis—commonly (among Northern Europeans) homozygosity for *HFE* C282Y but sometimes involving non-C282Y *HFE* or other genes (*HAMP, HFE2* [encoding hemojuvelin], *TFR2, SLC40A1*).
Substantial ineffective erythropoiesis (e.g., β thalassemia intermedia and major, some types of sideroblastic anemia, congenital dyserythropoietic anemia).
Sub-Saharan iron overload ("Bantu siderosis")—only in combination with increased dietary iron.
Other rare inherited disorders (e.g., congenital atransferrinemia, DMT1 deficiency, aceruloplasminemia).
Inappropriate iron therapy (rare).

DUE TO MULTIPLE BLOOD TRANSFUSIONS FOR REFRACTORY ANEMIAS OR FOR OTHER REASONS

Thalassemia major.
Aplastic anemia.
Myelodysplastic syndromes.
Sickle cell disease (when regularly transfused).

IRON OVERLOAD[45]

ICD-10CM # E83.10 Disorder of iron metabolism, unspecified

HEREDITARY IRON OVERLOAD

Hereditary hemochromatosis:
- HFE-associated (type 1).
- Non–HFE-associated:
  - Transferrin receptor 2–associated (type 3).

Juvenile hemochromatosis (type 2):
- Hemojuvelin-associated (type 2A).
- Hepcidin-associated (type 2B).

Autosomal dominant hemochromatosis:
- Ferroportin-associated (type 4).
- DMT1-associated hemochromatosis.
- Atransferrinemia.
- Aceruloplasminemia.

ACQUIRED IRON OVERLOAD

Iron-loading anemias (refractory anemias with hypercellular erythroid marrow).
Chronic liver disease.
Porphyria cutanea tarda.
Insulin resistance–associated hepatic iron overload.
African dietary iron overload.[24]
Medical iron ingestion.
Parenteral iron overload:
- Transfusional iron overload.
- Inadvertent iron overload from therapeutic injections.

PERINATAL IRON OVERLOAD

Neonatal hemochromatosis.
Trichohepatoenteric syndrome.
Cerebrohepatorenal syndrome.
GRACILE[25] (Fellman) syndrome.

FOCAL SEQUESTRATION OF IRON

Idiopathic pulmonary hemosiderosis.
Renal hemosiderosis.
Associated with neurologic abnormalities:
- Pantothenate kinase–associated neurodegeneration (formerly called Hallervorden-Spatz syndrome).
- Neuroferritinopathy.
- Friedreich ataxia.

[24] May have a genetic component.
[25] GRACILE, Growth retardation, aminoaciduria, cholestasis, iron overload, lactic acidosis, and early death.

ISCHEMIA, UPPER EXTREMITY, CAUSES[15]

ICD-10CM #		
	S45.809A	Unspecified injury of other specified blood vessels at shoulder and upper arm level, unspecified arm, initial encounter

VASOSPASM

Raynaud disease.
Medication induced: vasopressors, β-blockers.
Ergot poisoning.

INTRINSIC ARTERIAL DISEASE

Atherosclerosis.
Radiation arteritis.
Azotemic arteriopathy.
Spontaneous dissection.
Fibromuscular dysplasia.

INFLAMMATORY DISEASES

Connective tissue disorders.
Buerger disease.
Takayasu arteritis.
Temporal (giant cell) arteritis.
Hypersensitivity angiitis.

NONINFLAMMATORY MEDICAL DISEASE

Thrombophilic states.
Myeloproliferative disorders.
Cold injury.
Hepatitis-associated vasculitis.
Cryoglobulinemia.
Vinyl chloride exposure.

EMBOLISM

Cardiac (most common).
Proximal aneurysm.
Arterial thoracic outlet syndrome.
Atheroembolism.
Paradoxic embolus (with accompanying septal defect).

TRAUMA

Iatrogenic.
Blunt arterial injury.
Penetrating arterial injury.
Hypothenar hammer syndrome.
Vibration.

ISCHEMIC BOWEL DISEASE[1]

ICD-10CM #		
	K55.1	Vascular disorder of intestine
	I99	Other and unspecified disorders of circulatory system

Abdominal aortic aneurysm: rupture or expansion.
Perforated ulcer or viscus.
Ruptured ectopic pregnancy (woman of childbearing age).
Incarcerated or strangulated hernia.
Septic shock.
Intussusception.
Volvulus.
Salpingitis or tuboovarian abscess.
Torsion of the ovary or testicle.
Appendicitis.
Pelvic mass or torsion.
Pancreatitis.
Diverticulitis.
Ruptured ovarian cyst.
Renal colic.
Biliary colic.
Also consider atypical manifestations of:
- Inferior wall myocardial infarction.
- Pulmonary embolism.
- Pneumonia.
- Diabetic ketoacidosis.
- Acute glaucoma.

Differential diagnoses are listed in order of urgency.

ISCHEMIC COLITIS, NONOCCLUSIVE[49]

ICD-10CM #		
	K55.1	Chronic vascular disorders of intestine

ACUTE DIMINUTION OF COLONIC INTRAMURAL BLOOD FLOW

Small Vessel Obstruction
Collagen-vascular disease.
Vasculitis, diabetes.
Oral contraceptives.
Nonocclusive Hypoperfusion
Hemorrhage.
CHF, MI, arrhythmias.
Sepsis.
Vasoconstricting agents: vasopressin, ergot.
Increased viscosity: polycythemia, sickle cell disease, thrombocytosis.

INCREASED DEMAND ON MARGINAL BLOOD FLOW

Increased Motility
Mass lesion, stricture.
Constipation.
Increased Intraluminal Pressure
Bowel obstruction.
Colonoscopy.
Barium enema.

ISCHEMIC NECROSIS OF CARTILAGE AND BONE[32]

ICD-10CM #		
	M89.9	Disorder of bone, unspecified
	M94.9	Disorder of cartilage, unspecified

ENDOCRINE/METABOLIC

Ethanol abuse.
Glucocorticoid therapy.
Cushing disease.
DM.
Hyperuricemia.
Osteomalacia.
Hyperlipidemia.

STORAGE DISEASES (E.G., GAUCHER DISEASE)

Hemoglobinopathies (e.g., sickle cell disease).
Trauma (e.g., dislocation, fracture).
HIV infection.
Dysbaric conditions (e.g., caisson disease).
Collagen-vascular disorders.
Irradiation.
Pancreatitis.
Organ transplantation.
Hemodialysis.
Burns.
Intravascular coagulation.
Idiopathic, familial.

JAUNDICE

ICD-10CM #		
	R17	Unspecified jaundice
	K83.8	Other specified diseases of biliary tract
	E80.7	Disorder of bilirubin metabolism, unspecified

PREDOMINANCE OF DIRECT (CONJUGATED) BILIRUBIN

Extrahepatic obstruction.
Common duct abnormalities: calculi, neoplasm, stricture, cyst, sclerosing cholangitis.
Metastatic carcinoma.
Pancreatic carcinoma, pseudocyst.
Ampullary carcinoma.
Hepatocellular disease: hepatitis, cirrhosis.
Drugs: estrogens, phenothiazines, captopril, methyltestosterone, labetalol.
Cholestatic jaundice of pregnancy.
Hereditary disorders: Dubin-Johnson syndrome, Rotor syndrome.
Recurrent benign intrahepatic cholestasis.

PREDOMINANCE OF INDIRECT (UNCONJUGATED) BILIRUBIN

Hemolysis: hereditary and acquired hemolytic anemias.
Inefficient marrow production.
Impaired hepatic conjugation: chloramphenicol.
Neonatal jaundice.
Hereditary disorders: Gilbert syndrome, Crigler-Najjar syndrome.

JAUNDICE, CLASSIFICATION[3]

ICD-10CM #		
	R17	Unspecified jaundice

PREHEPATIC (PREDOMINANTLY UNCONJUGATED HYPERBILIRUBINEMIA)

Overproduction
Hemolysis (e.g., spherocytosis, sickle cell disease, hemolysis of the newborn, autoimmune disorders).
Ineffective erythropoiesis (e.g., megaloblastic anemias).
Hematomas.
Pulmonary emboli.

HEPATIC (UNCONJUGATED HYPERBILIRUBINEMIA)

Decreased Hepatic Uptake
Gilbert syndrome.
Drugs (e.g., rifampin, radiographic contrast agents).
Neonatal jaundice.
Posthepatitis.
Decreased cystolic binding proteins (e.g., newborn or premature infants).
Portacaval shunt.

ISCHEMIA, UPPER EXTREMITY, CAUSES[15]

ICD-10CM #		
	S45.809A	Unspecified injury of other specified blood vessels at shoulder and upper arm level, unspecified arm, initial encounter

VASOSPASM

Raynaud disease.
Medication induced: vasopressors, β-blockers.
Ergot poisoning.

INTRINSIC ARTERIAL DISEASE

Atherosclerosis.
Radiation arteritis.
Azotemic arteriopathy.
Spontaneous dissection.
Fibromuscular dysplasia.

INFLAMMATORY DISEASES

Connective tissue disorders.
Buerger disease.
Takayasu arteritis.
Temporal (giant cell) arteritis.
Hypersensitivity angiitis.

NONINFLAMMATORY MEDICAL DISEASE

Thrombophilic states.
Myeloproliferative disorders.
Cold injury.
Hepatitis-associated vasculitis.
Cryoglobulinemia.
Vinyl chloride exposure.

EMBOLISM

Cardiac (most common).
Proximal aneurysm.
Arterial thoracic outlet syndrome.
Atheroembolism.
Paradoxic embolus (with accompanying septal defect).

TRAUMA

Iatrogenic.
Blunt arterial injury.
Penetrating arterial injury.
Hypothenar hammer syndrome.
Vibration.

ISCHEMIC BOWEL DISEASE[1]

ICD-10CM #		
	K55.1	Vascular disorder of intestine
	I99	Other and unspecified disorders of circulatory system

Abdominal aortic aneurysm: rupture or expansion.
Perforated ulcer or viscus.
Ruptured ectopic pregnancy (woman of childbearing age).
Incarcerated or strangulated hernia.
Septic shock.
Intussusception.
Volvulus.
Salpingitis or tuboovarian abscess.
Torsion of the ovary or testicle.
Appendicitis.
Pelvic mass or torsion.
Pancreatitis.
Diverticulitis.
Ruptured ovarian cyst.
Renal colic.
Biliary colic.
Also consider atypical manifestations of:
- Inferior wall myocardial infarction.
- Pulmonary embolism.
- Pneumonia.
- Diabetic ketoacidosis.
- Acute glaucoma.

Differential diagnoses are listed in order of urgency.

ISCHEMIC COLITIS, NONOCCLUSIVE[49]

Hereditary disorders: Dubin-Johnson syndrome, Rotor syndrome.
Recurrent benign intrahepatic cholestasis.

PREDOMINANCE OF INDIRECT (UNCONJUGATED) BILIRUBIN

Hemolysis: hereditary and acquired hemolytic anemias.
Inefficient marrow production.
Impaired hepatic conjugation: chloramphenicol.
Neonatal jaundice.
Hereditary disorders: Gilbert syndrome, Crigler-Najjar syndrome.

JAUNDICE, CLASSIFICATION[3]

ICD-10CM #		
	R17	Unspecified jaundice

PREHEPATIC (PREDOMINANTLY UNCONJUGATED HYPERBILIRUBINEMIA)

Overproduction
Hemolysis (e.g., spherocytosis, sickle cell disease, hemolysis of the newborn, autoimmune disorders).
Ineffective erythropoiesis (e.g., megaloblastic anemias).
Hematomas.
Pulmonary emboli.

HEPATIC (UNCONJUGATED HYPERBILIRUBINEMIA)

Decreased Hepatic Uptake
Gilbert syndrome.
Drugs (e.g., rifampin, radiographic contrast agents).
Neonatal jaundice.
Posthepatitis.
Decreased cystolic binding proteins (e.g., newborn or premature infants).
Portacaval shunt.

Prolonged fasting.

Decreased Conjugation Due to Limited Glucuronyl Transferase Activity

Gilbert disease.
Crigler-Najjar syndrome, types I and II.
Neonatal jaundice.
Breast-milk jaundice.
Chronic persistent hepatitis.
Wilson disease.
Noncirrhotic portal fibrosis.
Drug inhibition (e.g., chloramphenicol).

PREDOMINANTLY CONJUGATED HYPERBILIRUBINEMIA

Impaired Hepatic Excretion

Familial disorders (Dubin-Johnson syndrome, Rotor syndrome, benign recurrent cholestasis, cholestasis of pregnancy).
Hepatocellular infiltrative disorders.
Liver metastasis.
Liver cirrhosis.
Hepatitis (viral, bacterial, parasitic, autoimmune, ethanol, and drug-induced).
Drug-induced cholestasis (especially chlorpromazine, erythromycin estolate, isoniazid, halothane).
Primary biliary cirrhosis.
Primary sclerosing cholangitis.
Pericholangitis.
Congestive heart failure.
Shock.
Toxemia of pregnancy.
Sarcoidosis.
Hepatic trauma.
Amyloidosis.
Autoimmune cholangiopathy.
Vanishing bile duct syndrome.
Sepsis.
Postoperative complications.

EXTRAHEPATIC

Extrahepatic Biliary Obstruction

Gallstones, choledocholithiasis.
Cholecystitis.
Tumors of the head of the pancreas (adenocarcinoma, mucinous duct ectasia, neuroendocrine tumors, metastasis).
Tumors of bile ducts (cholangiocarcinoma, Klatskin tumor: cholangiocarcinoma at the bifurcation).
Gallbladder cancer.
Tumors of the ampulla of Vater (adenoma, adenocarcinoma).
Tumors of the duodenum (adenocarcinoma, lymphoma).
Hemobilia (blood in the biliary tree).
Biliary strictures (postcholecystectomy, postliver transplantation, primary sclerosing cholangitis).
Congenital disorders (biliary atresia, idiopathic dilation of common bile duct, cystic fibrosis).
Metastasis to the hepatic hilum.
Primary bile duct lymphoma.
Cholangiopathy of acquired immunodeficiency syndrome.
Choledochal cysts.
Infectious cholangiopathy *(Clonorchis sinensis, Ascaris lumbricoides, Fasciola hepatica).*
Chronic pancreatitis (fibrosis of the head of the pancreas).

JAUNDICE, NEONATAL[3]

ICD-10CM #	P59.9	Neonatal jaundice, unspecified

PREHEPATIC

Hereditary spherocytosis.
Nonspherocytic hemolytic anemia (glucose-6-phosphate dehydrogenase deficiency, α-thalassemia, vitamin K_3–induced hemolysis, pyruvate kinase deficiency).

HEPATIC

Crigler-Najjar syndrome, types I and II.
α_1-Antitrypsin deficiency.
Sepsis.
Drug-induced.
Hypothyroidism.
Breast-milk jaundice.
Fetomaternal blood group incompatibility (Rhesus, Landsteiner groups ABO).

POSTHEPATIC

Extrahepatic biliary obstruction.
Biliary atresia.
Bile duct paucity.
Alagille syndrome.

JOINT AND PERIARTICULAR PAIN, ACUTE[27]

ICD-10CM #	M25.50	Joint pain

COMMON ACUTE MONOARTHRITIS

Septic arthritis (nongonococcal, gonococcal).
Crystal arthritis (gout, pseudogout).
Reactive arthritides.
Lyme disease.
Plant thorn synovitis.
Other infections (mycobacterial, viral, soft tissue).

TRAUMA OR INTERNAL DERANGEMENT

Loose bodies.
Stress fractures.
Ischemic necrosis.
Hemarthrosis.

ACUTE MONOARTHRITIS OR POLYARTHRITIS

Psoriatic arthritis.
Enteropathic arthritis.
Rheumatoid arthritis/palindromic rheumatism.
Juvenile inflammatory arthritides.

MONOARTHROPATHIES FROM NONINFLAMMATORY DISEASE

Osteoarthritis.
Charcot joints.
Storage diseases (hemochromatosis, ochronosis).

SYNOVIAL DISEASES

Pigmented villonodular synovitis.
Lipoma arborescens.
Synovial osteochondromatosis.
Reflex sympathetic dystrophy.
Sarcoidosis.
Amyloid.

ACUTE MONOARTHRITIS OF SYSTEMIC DISEASE

Systemic lupus erythematosus.
Vasculitides (antineutrophil cytoplasmic antibody positive and negative).
Henoch-Schönlein purpura.
Behçet disease.
Bacterial endocarditis.
Familial Mediterranean fever.
Relapsing polychondritis.

SOFT TISSUE LESIONS

Bone Diseases

Paget disease.
Osteomyelitis (Brodie abscess).
Osteogenic/osteoid tumors.
Metastatic disease.
Pulmonary hypertrophic osteoarthropathy.

This table shows the causes of inflammation in any one joint (monoarthritis) and pain around the joint that presents without inflammation (monoarthropathy).

JOINT PAIN, ANTERIOR HIP, MEDIAL THIGH, KNEE[65]

ICD-10CM #	M25.50	Pain in unspecified joint
	M25.559	Pain in unspecified hip
	M25.569	Pain in unspecified knee

ACUTE

Acute rheumatic fever.
Adductor muscle strain.
Avascular necrosis.
Crystal arthritis.
Femoral artery (pseudo) aneurysm.
Fracture (femoral neck or intertrochanteric).
Hemarthrosis.
Hernia.
Herpes zoster.
Iliopectineal bursitis.
Iliopsoas tendinitis.
Inguinal lymphadenitis.
Osteomalacia.
Painful transient osteoporosis of hip.
Septic arthritis.

SUBACUTE AND CHRONIC

Adductory muscle strain.
Amyloidosis.
Acute rheumatic fever.
Femoral artery aneurysm.
Hernia (inguinal or femoral).
Iliopectineal bursitis.
Iliopsoas tendinitis.
Inguinal lymphadenopathy.
Osteochondromatosis.
Osteomyelitis.
Osteitis deformans (Paget disease).
Osteomalacia (pseudofracture).
Postherpetic neuralgia.
Sterile synovitis (e.g., RA, psoriatic, SLE).

JOINT PAIN, HIP, LATERAL THIGH[65]

ICD-10CM #	S79.919A	Unspecified injury of unspecified hip, initial encounter
	S79.929A	Unspecified injury of unspecified thigh, initial encounter
	M25.9	Joint disorder, unspecified

ACUTE

Herpes zoster.
Iliotibial tendinitis.
Impacted fracture of femoral neck.
Lateral femoral cutaneous neuropathy (meralgia paresthetica).
Radiculopathy: L4-5.
Trochanteric avulsion fracture (greater trochanter).
Trochanteric bursitis.
Trochanteric fracture.

SUBACUTE AND CHRONIC

Lateral femoral cutaneous neuropathy (meralgia paresthetica).
Osteomyelitis.
Postherpetic neuralgia.
Radiculopathy: L4-5.
Tumors.

JOINT PAIN, POLYARTICULAR

ICD-10CM #	M25.50	Pain in unspecified joint

Osteoarthritis.
RA.
Fibromyalgia.
Viral syndrome (e.g., human parvovirus B19 infection).
SLE.
Psoriatic arthritis.
Ankylosing spondylitis.

JOINT PAIN, POSTERIOR HIPS, THIGH, BUTTOCKS[65]

ICD-10CM #	M25.50	Pain in unspecified joint
	M25.559	Pain in unspecified hip
	M25.569	Pain in unspecified knee

ACUTE

Gluteal muscle strain.
Herpes zoster.
Ischial bursitis.
Ischial or sacral fracture.
Osteomalacia (pseudofracture).
Sciatic neuropathy.
Radiculopathy: L5-S1.

SUBACUTE AND CHRONIC

Gluteal muscle strain.
Ischial bursitis.
Lumbar spinal stenosis.
Osteoarthritis of hip.
Osteitis deformans (Paget disease).
Osteomyelitis.
Osteochondromatosis.
Osteomalacia (pseudofracture).
Postherpetic neuralgia.
Radiculopathy: L5-S1.
Tumors.

JOINT SWELLING

ICD-10CM #	M25.40	Effusion, unspecified joint

Trauma.
Osteoarthritis.
Gout.
Pyogenic arthritis.
Pseudogout.
RA.
Viral syndrome.

JUGULAR VENOUS DISTENTION

ICD-10CM #	I99.8	Other disorder of circulatory system

Right-sided heart failure.
Cardiac tamponade.
Constrictive pericarditis.
Goiter.
Tension pneumothorax.
Pulmonary hypertension.
Cardiomyopathy (restrictive).
Superior vena cava syndrome.
Valsalva maneuver.
Right atrial myxoma.
COPD.

KERATITIS, NONINFECTIOUS

ICD-10CM #	H16.9	Unspecified keratitis

Collagen vascular disease.
Atopic keratoconjunctivitis.
Chemical injury.
Thermal injury.
Ectropion/entropion.
Lid defects.
Exophthalmos.
Keratoconjunctivitis sicca.
Erythema multiforme.
Mucous membrane pemphigoid.
DM (delayed epithelial healing).
Neuroparalytic (cranial nerve VII).
Neurotrophic (diabetes, cranial nerve V).

KIDNEY CYSTIC DISEASE[90]

ICD-10CM #	Varies with specific diagnosis

CYSTIC DISEASES OF THE KIDNEY

Inheritable

Autosomal recessive (infantile) polycystic kidney disease.
Autosomal dominant (adult) polycystic kidney disease.
Juvenile nephronophthisis and medullary cystic disease complex.
Juvenile nephronophthisis (autosomal recessive).
Medullary cystic disease (autosomal dominant).
Congenital nephrosis (familial nephrotic syndrome) (autosomal recessive).
Familial hypoplastic glomerulocystic disease (autosomal dominant).
Multiple malformation syndromes with renal cysts (e.g., tuberous sclerosis, von Hippel-Lindau disease).

Nonheritable

Multicystic kidney (multicystic dysplastic kidney).
Benign multilocular cyst (cystic nephroma).
Simple cysts.
Medullary sponge kidney.
Sporadic glomerulocystic kidney disease.
Acquired renal cystic disease.
Calyceal diverticulum (pyelogenic cyst).

KIDNEY ENLARGEMENT, UNILATERAL[86]

ICD-10CM #	N13.30	Unspecified hydronephrosis

Hydronephrosis (may be bilateral).
Polycystic kidney (may be bilateral).
Simple cyst of kidney.
Renal cell carcinoma.
Pyonephrosis (may be bilateral).
Acute renal vein thrombosis.

KIDNEY INJURY, CANCER PATIENTS[79]

ICD-10CM #	Varies with specific diagnosis

CAUSES OF ACUTE KIDNEY INJURY IN CANCER PATIENTS

Prerenal

Sepsis
Volume depletion (vomiting, diarrhea, mucositis).
Hepatorenal syndrome (venoocclusive disease of the liver).
Capillary leak syndrome (interleukin-2 administration).
Hypercalcemia.

Intrinsic

Acute tubular necrosis
Ischemia (sepsis/shock).
Nephrotoxic (aminoglycosides, amphotericin B, chemotherapy).

Tubulointerstitial nephritis
Tumor lysis syndrome (urate and phosphate nephropathy).
Allergic reaction.
Pyelonephritis.
Opportunistic infections.
Infiltration (lymphoma/leukemia).

Vascular
Thrombotic microangiopathy.
Cancer treated.
Drug induced.

JOINT PAIN, HIP, LATERAL THIGH[65]

ICD-10CM #	S79.919A	Unspecified injury of unspecified hip, initial encounter
	S79.929A	Unspecified injury of unspecified thigh, initial encounter
	M25.9	Joint disorder, unspecified

ACUTE

Herpes zoster.
Iliotibial tendinitis.
Impacted fracture of femoral neck.
Lateral femoral cutaneous neuropathy (meralgia paresthetica).
Radiculopathy: L4-5.
Trochanteric avulsion fracture (greater trochanter).
Trochanteric bursitis.
Trochanteric fracture.

SUBACUTE AND CHRONIC

Lateral femoral cutaneous neuropathy (meralgia paresthetica).
Osteomyelitis.
Postherpetic neuralgia.
Radiculopathy: L4-5.
Tumors.

JOINT PAIN, POLYARTICULAR

ICD-10CM #	M25.50	Pain in unspecified joint

Osteoarthritis.
RA.
Fibromyalgia.
Viral syndrome (e.g., human parvovirus B19 infection).
SLE.
Psoriatic arthritis.
Ankylosing spondylitis.

JOINT PAIN, POSTERIOR HIPS, THIGH, BUTTOCKS[65]

ICD-10CM #	M25.50	Pain in unspecified joint
	M25.559	Pain in unspecified hip
	M25.569	Pain in unspecified knee

ACUTE

Gluteal muscle strain.
Herpes zoster.
Ischial bursitis.
Ischial or sacral fracture.
Osteomalacia (pseudofracture).
Sciatic neuropathy.
Radiculopathy: L5-S1.

SUBACUTE AND CHRONIC

Gluteal muscle strain.
Ischial bursitis.
Lumbar spinal stenosis.
Osteoarthritis of hip.
Osteitis deformans (Paget disease).
Osteomyelitis.
Osteochondromatosis.
Osteomalacia (pseudofracture).
Postherpetic neuralgia.
Radiculopathy: L5-S1.
Tumors.

JOINT SWELLING

ICD-10CM #	M25.40	Effusion, unspecified joint

Trauma.
Osteoarthritis.
Gout.
Pyogenic arthritis.
Pseudogout.
RA.
Viral syndrome.

JUGULAR VENOUS DISTENTION

ICD-10CM #	I99.8	Other disorder of circulatory system

Right-sided heart failure.
Cardiac tamponade.
Constrictive pericarditis.
Goiter.
Tension pneumothorax.
Pulmonary hypertension.
Cardiomyopathy (restrictive).
Superior vena cava syndrome.
Valsalva maneuver.
Right atrial myxoma.
COPD.

KERATITIS, NONINFECTIOUS

ICD-10CM #	H16.9	Unspecified keratitis

Collagen vascular disease.
Atopic keratoconjunctivitis.
Chemical injury.
Thermal injury.
Ectropion/entropion.
Lid defects.
Exophthalmos.
Keratoconjunctivitis sicca.
Erythema multiforme.
Mucous membrane pemphigoid.
DM (delayed epithelial healing).
Neuroparalytic (cranial nerve VII).
Neurotrophic (diabetes, cranial nerve V).

KIDNEY CYSTIC DISEASE[90]

ICD-10CM #	Varies with specific diagnosis

CYSTIC DISEASES OF THE KIDNEY

Inheritable

Autosomal recessive (infantile) polycystic kidney disease.
Autosomal dominant (adult) polycystic kidney disease.
Juvenile nephronophthisis and medullary cystic disease complex.
Juvenile nephronophthisis (autosomal recessive).
Medullary cystic disease (autosomal dominant).
Congenital nephrosis (familial nephrotic syndrome) (autosomal recessive).
Familial hypoplastic glomerulocystic disease (autosomal dominant).
Multiple malformation syndromes with renal cysts (e.g., tuberous sclerosis, von Hippel-Lindau disease).

Nonheritable

Multicystic kidney (multicystic dysplastic kidney).
Benign multilocular cyst (cystic nephroma).
Simple cysts.
Medullary sponge kidney.
Sporadic glomerulocystic kidney disease.
Acquired renal cystic disease.
Calyceal diverticulum (pyelogenic cyst).

KIDNEY ENLARGEMENT, UNILATERAL[86]

ICD-10CM #	N13.30	Unspecified hydronephrosis

Hydronephrosis (may be bilateral).
Polycystic kidney (may be bilateral).
Simple cyst of kidney.
Renal cell carcinoma.
Pyonephrosis (may be bilateral).
Acute renal vein thrombosis.

KIDNEY INJURY, CANCER PATIENTS[79]

ICD-10CM #	Varies with specific diagnosis

CAUSES OF ACUTE KIDNEY INJURY IN CANCER PATIENTS

Prerenal

Sepsis
Volume depletion (vomiting, diarrhea, mucositis).
Hepatorenal syndrome (venoocclusive disease of the liver).
Capillary leak syndrome (interleukin-2 administration).
Hypercalcemia.

Intrinsic

Acute tubular necrosis
Ischemia (sepsis/shock).
Nephrotoxic (aminoglycosides, amphotericin B, chemotherapy).

Tubulointerstitial nephritis
Tumor lysis syndrome (urate and phosphate nephropathy).
Allergic reaction.
Pyelonephritis.
Opportunistic infections.
Infiltration (lymphoma/leukemia).

Vascular
Thrombotic microangiopathy.
Cancer treated.
Drug induced.

Bone marrow transplantation.
Radiation injury.
Amyloidosis
Light-chain deposition disease
Paraneoplastic syndromes (membranous, antineutrophil cytoplasmic antibody associated, focal segmental glomerulosclerosis)
Postrenal
Intrarenal (urate, acyclovir, methotrexate)
Extrarenal (retroperitoneal fibrosis, lymphadenopathy, direct invasion)

KNEE PAIN[65]

ICD-10CM #		
	S83.419A	Sprain of medial collateral ligament of unspecified knee, initial encounter
	S83.509A	Sprain of unspecified cruciate ligament of unspecified knee, initial encounter
	M23.50	Chronic instability of knee, unspecified knee
	M23.8X9	Other internal derangements of unspecified knee
	S83.289A	Other tear of lateral meniscus, current injury, unspecified knee, initial encounter
	S83.249A	Other tear of medial meniscus, current injury, unspecified knee, initial encounter
	M25.669	Stiffness of unspecified knee, not elsewhere classified

DIFFUSE

Articular.
Anterior.
Prepatellar bursitis.
Patellar tendon enthesopathy.
Chondromalacia patellae.
Patellofemoral osteoarthritis.
Cruciate ligament injury.
Medial plica syndrome.

MEDIAL

Anserine bursitis.
Spontaneous osteonecrosis.
Osteoarthritis.
Medial meniscal tear.
Medial collateral ligament bursitis.
Referred pain from hip and L3.
Fibromyalgia.

LATERAL

Iliotibial band syndrome.
Meniscal cyst.
Lateral meniscal tear.
Collateral ligament.
Peroneal tenosynovitis.

POSTERIOR

Popliteal cyst (Baker cyst).
Tendinitis.
Aneurysms, ganglions, sarcoma.

KNEE PAIN, IN DIFFERENT AGE GROUPS[18]

ICD-10CM #	M25.569	Pain in unspecified knee

COMMON CAUSES OF KNEE PAIN IN DIFFERENT AGE GROUPS

Childhood (2 to 10 yr)
Intraarticular
Juvenile arthritis.
Osteochondritis dissecans.
Infection.
Torn discoid meniscus.
Periarticular
Osteomyelitis.
Referred
Perthes disease.
Irritable hip.
Adolescence (10 to 18 yr)
Intraarticular
Osteochondritis dissecans.
Torn meniscus.
Anterior knee pain syndrome.
Patellar instability.
Periarticular
Osgood–Schlatter disease.
Sinding–Larsen–Johansson syndrome.
Osteomyelitis.
Bone tumors.
Referred
Slipped upper femoral epiphysis.
Early Adulthood (18 to 30 yr)
Intraarticular
Torn meniscus.
Patellar instability.
Anterior knee pain syndrome.
Inflammatory arthritis.
Periarticular
Ligament injuries.
Bursitis.
Adulthood (30 to 50 yr)
Intraarticular
Degenerate meniscal tears.
Osteoarthritis.
Inflammatory arthritis.
Periarticular
Bursitis.
Referred
Osteoarthritis of hip.
Spinal disorders.
Old Age (>50 yr)
Intraarticular
Osteoarthritis.
Inflammatory arthritis.
Periarticular
Bursitis.
Referred
Osteoarthritis of hip.
Spinal disorders.

LARGE BOWEL STRICTURE[36]

ICD-10CM #	S36.5	Injury of colon

CAUSES OF LARGE BOWEL STRICTURES

Physiologic:
- Spasm.
- Distended bladder.

Malignant:
- Annular carcinoma.
- Scirrhous carcinoma.
- Lymphoma.

Diverticular disease:
- Muscle thickening.
- Pericolic abscess.
- Superimposed malignancy.

Ischemia.
Radiation colitis.
Inflammatory bowel disease:
- Ulcerative colitis.
- Crohn disease.
- Tuberculosis.
- Lymphogranuloma venereum.
- Amebiasis.

Extrinsic disease:
- Intraabdominal masses.
- Metastatic carcinoma.
- Endometriosis.
- Pelvic lipomatosis.
- Cholecystitis.
- Pancreatitis.
- Miscellaneous:

Postoperative anastomosis.
Trauma.
Hirschsprung disease.

LEFT AXIS DEVIATION[52]

ICD-10CM #	I44.7	Left bundle-branch block, unspecified
	I44.4	Left anterior fascicular block
	I44.5	Left posterior fascicular block
	I44.60	Unspecified fascicular block
	I44.69	Other fascicular block

Normal variation.
Left anterior fascicular block (hemiblock).
Left bundle branch block.
Left ventricular hypertrophy.
Mechanical shifts causing a horizontal heart, high diaphragm, pregnancy, ascites.
Some forms of ventricular tachycardia.
Endocardial cushion defects and other congenital heart disease.

LEFT BUNDLE BRANCH BLOCK

ICD-10CM #	I44.7	Left bundle-branch block, unspecified

Ischemic heart disease.
Electrolyte abnormalities (e.g., hyperkalemia).

Bone marrow transplantation.
Radiation injury.
Amyloidosis
Light-chain deposition disease
Paraneoplastic syndromes (membranous, antineutrophil cytoplasmic antibody associated, focal segmental glomerulosclerosis)
Postrenal
Intrarenal (urate, acyclovir, methotrexate)
Extrarenal (retroperitoneal fibrosis, lymphadenopathy, direct invasion)

KNEE PAIN[65]

ICD-10CM #		
	S83.419A	Sprain of medial collateral ligament of unspecified knee, initial encounter
	S83.509A	Sprain of unspecified cruciate ligament of unspecified knee, initial encounter
	M23.50	Chronic instability of knee, unspecified knee
	M23.8X9	Other internal derangements of unspecified knee
	S83.289A	Other tear of lateral meniscus, current injury, unspecified knee, initial encounter
	S83.249A	Other tear of medial meniscus, current injury, unspecified knee, initial encounter
	M25.669	Stiffness of unspecified knee, not elsewhere classified

DIFFUSE

Articular.
Anterior.
Prepatellar bursitis.
Patellar tendon enthesopathy.
Chondromalacia patellae.
Patellofemoral osteoarthritis.
Cruciate ligament injury.
Medial plica syndrome.

MEDIAL

Anserine bursitis.
Spontaneous osteonecrosis.
Osteoarthritis.
Medial meniscal tear.
Medial collateral ligament bursitis.
Referred pain from hip and L3.
Fibromyalgia.

LATERAL

Iliotibial band syndrome.
Meniscal cyst.
Lateral meniscal tear.
Collateral ligament.
Peroneal tenosynovitis.

POSTERIOR

Popliteal cyst (Baker cyst).
Tendinitis.
Aneurysms, ganglions, sarcoma.

KNEE PAIN, IN DIFFERENT AGE GROUPS[18]

ICD-10CM #	M25.569	Pain in unspecified knee

COMMON CAUSES OF KNEE PAIN IN DIFFERENT AGE GROUPS

Childhood (2 to 10 yr)
Intraarticular
Juvenile arthritis.
Osteochondritis dissecans.
Infection.
Torn discoid meniscus.
Periarticular
Osteomyelitis.
Referred
Perthes disease.
Irritable hip.
Adolescence (10 to 18 yr)
Intraarticular
Osteochondritis dissecans.
Torn meniscus.
Anterior knee pain syndrome.
Patellar instability.
Periarticular
Osgood–Schlatter disease.
Sinding–Larsen–Johansson syndrome.
Osteomyelitis.
Bone tumors.
Referred
Slipped upper femoral epiphysis.
Early Adulthood (18 to 30 yr)
Intraarticular
Torn meniscus.
Patellar instability.
Anterior knee pain syndrome.
Inflammatory arthritis.
Periarticular
Ligament injuries.
Bursitis.
Adulthood (30 to 50 yr)
Intraarticular
Degenerate meniscal tears.
Osteoarthritis.
Inflammatory arthritis.
Periarticular
Bursitis.
Referred
Osteoarthritis of hip.
Spinal disorders.
Old Age (>50 yr)
Intraarticular
Osteoarthritis.
Inflammatory arthritis.
Periarticular
Bursitis.
Referred
Osteoarthritis of hip.
Spinal disorders.

LARGE BOWEL STRICTURE[36]

ICD-10CM #	S36.5	Injury of colon

CAUSES OF LARGE BOWEL STRICTURES

Physiologic:
- Spasm.
- Distended bladder.

Malignant:
- Annular carcinoma.
- Scirrhous carcinoma.
- Lymphoma.

Diverticular disease:
- Muscle thickening.
- Pericolic abscess.
- Superimposed malignancy.

Ischemia.
Radiation colitis.
Inflammatory bowel disease:
- Ulcerative colitis.
- Crohn disease.
- Tuberculosis.
- Lymphogranuloma venereum.
- Amebiasis.

Extrinsic disease:
- Intraabdominal masses.
- Metastatic carcinoma.
- Endometriosis.
- Pelvic lipomatosis.
- Cholecystitis.
- Pancreatitis.
- Miscellaneous:

Postoperative anastomosis.
Trauma.
Hirschsprung disease.

LEFT AXIS DEVIATION[52]

ICD-10CM #	I44.7	Left bundle-branch block, unspecified
	I44.4	Left anterior fascicular block
	I44.5	Left posterior fascicular block
	I44.60	Unspecified fascicular block
	I44.69	Other fascicular block

Normal variation.
Left anterior fascicular block (hemiblock).
Left bundle branch block.
Left ventricular hypertrophy.
Mechanical shifts causing a horizontal heart, high diaphragm, pregnancy, ascites.
Some forms of ventricular tachycardia.
Endocardial cushion defects and other congenital heart disease.

LEFT BUNDLE BRANCH BLOCK

ICD-10CM #	I44.7	Left bundle-branch block, unspecified

Ischemic heart disease.
Electrolyte abnormalities (e.g., hyperkalemia).

Cardiomyopathy.
Idiopathic.
LVH.
Pulmonary embolism.
Cardiac trauma.
Bacterial endocarditis.

LEG CRAMPS, NOCTURNAL

ICD-10CM #		
	R25.2	Cramp and spasm

Diabetic neuropathy.
Medications.
Electrolyte abnormalities (hypokalemia, hyponatremia, hypocalcemia, hyperkalemia, hypophosphatemia).
Respiratory alkalosis.
Uremia.
Hemodialysis.
Peripheral nerve injury.
ALS.
Alcohol use.
Heat cramps.
Vitamin B_{12} deficiency.
Hyperthyroidism.
Contractures.
DVT.
Hypoglycemia.
Peripheral vascular insufficiency.
Baker cyst.

LEG LENGTH DISCREPANCIES[55]

ICD-10CM #		
	M21.759	Unequal limb length (acquired), unspecified femur
	M21.769	Unequal limb length (acquired), unspecified tibia and fibula
	Q72.899	Other reduction defects of unspecified lower limb

CONGENITAL

Proximal femoral local deficiency.
Coxa vara.
Hemiatrophy-hemihypertrophy (anisomelia).
Developmental dysplasia of the hip.

DEVELOPMENTAL

Legg-Calvé-Perthes disease.

NEUROMUSCULAR

Polio.
Cerebral palsy (hemiplegia).

INFECTIOUS

Pyogenic osteomyelitis with physeal damage.

TRAUMA

Physeal injury with premature closure.
Overgrowth.
Malunion (shortening).

TUMOR

Physeal destruction.
Radiation-induced physeal injury.
Overgrowth.

LEG MOVEMENT WHEN STANDING, INVOLUNTARY

ICD-10CM #		
	R25.8	Other abnormal involuntary movements

Benign essential tremor.
Orthostatic tremor.
Spastic ataxia.
Cerebellar truncal tremor.
Postanoxic myoclonus.

LEG PAIN, EXERTIONAL[95]

ICD-10CM #		
	R25.2	Cramp and spasm

Vascular Causes

Atherosclerosis.
Thrombosis.
Embolism.
Vasculitis:
- Thromboangiitis obliterans.
- Takayasu arteritis.
- Giant cell arteritis.

Aortic coarctation.
Fibromuscular dysplasia.
Irradiation.
Endofibrosis of the external iliac artery.
Extravascular compression:
- Arterial entrapment (e.g., popliteal artery entrapment, thoracic outlet syndrome).

Adventitial cysts.

Nonvascular Causes

Lumbosacral radiculopathy:
- Degenerative arthritis.
- Spinal stenosis.
- Herniated disc.

Arthritis:
- Hips, knees.

Venous insufficiency.
Myositis.
Glycogen storage disease type V (McArdle syndrome).

LEG PAIN WITH EXERCISE

ICD-10CM #		
	R25.2	Cramp and spasm

Shin splints.
Arteriosclerosis obliterans.
Neurogenic (spinal cord compression or ischemia).
Venous claudication.
Popliteal cyst.
DVT.
Thromboangiitis obliterans.
Adventitial cysts.
Popliteal artery entrapment syndrome.
McArdle syndrome.

LEG SWELLING[1]

ICD-10CM #		
	R60.0	Localized edema

Deep vein thrombosis.
Cellulitis.
Baker cyst rupture or inflammation.
Congestive heart failure.
Renal failure.
Liver failure.
Inferior vena cava compression.
Musculoskeletal trauma.
Polyarteritis nodosa.
Erythema nodosum.
Myositis.
Tendinitis.
Lymphedema.
Superficial thrombophlebitis.
Compartment syndrome.

LEG ULCERS[65]

ICD-10CM #		
	I70.25	Atherosclerosis of native arteries of other extremities with ulceration
	L97.909	Non-pressure chronic ulcer of unspecified part of unspecified lower leg with unspecified severity

VASCULAR

Arterial: arteriosclerosis, thromboangiitis obliterans, AV malformation, cholesterol emboli.
Venous: superficial varicosities, incompetent perforators, DVT, lymphatic abnormalities.

VASCULITIS HEMATOLOGIC

Sickle cell anemia, thalassemia, polycythemia vera, leukemia, cold agglutinin disease.
Macroglobulinemia, protein C and protein S deficiency, cryoglobulinemia, lupus anticoagulant, antiphospholipid syndrome.

INFECTIOUS

Fungal: blastomycosis, coccidioidomycosis, histoplasmosis, sporotrichosis.
Bacterial: Furuncle, ecthyma, septic emboli.
Protozoal: leishmaniasis.

METABOLIC

Necrobiosis lipoidica diabeticorum.
Localized bullous pemphigoid.
Gout, calcinosis cutis, Gaucher disease.

TUMORS

Basal cell carcinoma, squamous cell carcinoma, melanoma.
Mycosis fungoides, Kaposi sarcoma, metastatic neoplasms.

TRAUMA

Burns, cold injury, radiation dermatitis.
Insect bites.
Factitial, excessive pressure.

NEUROPATHIC

Diabetic trophic ulcers.
Tabes dorsalis, syringomyelia.

DRUGS

Warfarin, IV colchicine extravasation, methotrexate, halogens, ergotism, hydroxyurea.

PANNICULITIS

Weber-Christian disease.
Pancreatic fat necrosis, alpha-antitrypsinase deficiency.

LEPTOMENINGEAL LESIONS

ICD-10CM #		
	G03.9	Leptomeningitis

Metastases.
Multiple sclerosis.
Bacterial or viral meningitis.
Vasculitis.
Lyme disease.
Tuberculosis.
Fungal infections (e.g., *Cryptococcus*).
Sarcoidosis.
Granulomatosis with polyangiitis.
Neurocysticercosis.
Rheumatoid nodules.
Histiocytosis.

LEUKOCORIA

ICD-10CM #		
	H57.9	Unspecified disorder of eye and adnexa

Cataract.
Retinal detachment.
Retinoblastoma.
Retinal telangiectasia.
Retrolenticular vascularized membrane.
Familial exudative vitreoretinopathy.

LID RETRACTION, CAUSES[48]

ICD-10CM #		
	H02.539	Eyelid retraction unspecified eye, unspecified lid

Thyroid eye disease.
Neurogenic:
- Contralateral unilateral ptosis.
- Unopposed levator action due to facial palsy.
- 3rd nerve misdirection.
- Marcus Gunn jaw-winking syndrome.
- Collier sign of the dorsal midbrain (Parinaud syndrome).
- Infantile hydrocephalus (setting sun sign).
- Parkinsonism.
- Sympathomimetic drops.

Mechanical:
- Surgical over-correction of ptosis.
- Scarring of upper lid skin.

Congenital:
- Isolated.
- Duane retraction syndrome.
- Down syndrome.
- Transient "eye popping" reflex in normal infants.

Miscellaneous:
- Prominent globe (pseudo-lid retraction).
- Uremia (Summerskill sign).
- Idiopathic.

LIGHT-NEAR DISSOCIATION[12]

ICD-10CM #	
	Varies with specific diagnosis

CAUSES OF LIGHT-NEAR DISSOCIATION

Unilateral
Afferent conduction defect.
Adie pupil.
Herpes zoster ophthalmicus.
Aberrant regeneration of the third cranial nerve.

Bilateral
Neurosyphilis.
Type 1 diabetes mellitus.
Myotonic dystrophy.
Parinaud (dorsal midbrain) syndrome.
Familial amyloidosis.
Encephalitis.
Chronic alcoholism.

LIMB ISCHEMIA, ACUTE, NONTRAUMATIC[15]

ICD-10CM #		
	I70.2	Atherosclerosis of arteries of extremities

CAUSES OF NONTRAUMATIC ACUTE LIMB ISCHEMIA

Atherosclerotic
In situ thrombosis.
Atheroembolism from thoracic aortic aneurysm/abdominal aortic aneurysm.
Femoral/popliteal aneurysm with or without compression.
Dissection.

Nonatherosclerotic
Embolism from cardiac thrombosis (atrial fibrillation, post–myocardial infarction akinesis).
Graft thrombosis, graft aneurysm.
Mycotic emboli.
Raynaud phenomenon.
Arteritis with thrombosis.
Inherited and acquired hypercoagulable states.
Drug-induced vasospasm.
External compression (Baker cyst, popliteal entrapment).

Mimics
Phlegmasia cerulea dolens.
Acute neuropathy.
Hypovolemia.
Systemic shock.

LIMP

ICD-10CM #		
	R26.0	Ataxic gait
	R26.1	Paralytic gait
	R26.89	Other abnormalities of gait and mobility
	R26.9	Unspecified abnormalities of gait and mobility
	M25.80	Other specified joint disorders, unspecified joint
	F44.4	Conversion disorder with motor symptom or deficit
	F44.6	Conversion disorder with sensory symptom or deficit

Degenerative joint disease, osteochondritis dissecans, chondromalacia patellae.
Trauma to extremities, vertebral disk, hips.
Poorly fitting shoes, foreign body in shoe, unequal leg length.
Splinter in foot.
Joint infection (septic arthritis, osteomyelitis), viral arthritis.
Abdominal pain (e.g., appendicitis, incarcerated hernia), testicular torsion.
Polio, neuromuscular disorders, Guillain-Barré syndrome, multiple sclerosis.
Osgood-Schlatter disease.
Legg-Calvé-Perthes disease.
Factitious, somatization syndrome.
Neoplasm (local or metastatic).
Other: diskitis, periostitis, sickle cell disease, hemophilia.

LIMPING, PEDIATRIC AGE[55]

ICD-10CM #		
	R26.0	Ataxic gait
	R26.1	Paralytic gait
	R26.89	Other abnormalities of gait and mobility
	R26.9	Unspecified abnormalities of gait and mobility

TODDLER (1 TO 3 YR)

Infection:
- Septic arthritis:
  - Hip.
  - Knee.
- Osteomyelitis.
- Diskitis.

Occult trauma:
- Toddler's fracture.

Neoplasia.

CHILDHOOD (4 TO 10 YR)

Infection:
- Septic arthritis:
  - Hip.
  - Knee.
- Osteomyelitis.
- Diskitis.
- Transient synovitis, hip.

LCPD.
Tarsal coalition.
Rheumatologic disorder:
- JRA.

Trauma.
Neoplasia.

ADOLESCENCE (11+ YR)

SCFE.
Rheumatologic disorder:
- JRA.
- Trauma.
- Tarsal coalition.
- Hip dislocation (DDH).
- Neoplasia.

DDH, Developmental dysplasia of the hip; *JRA,* juvenile RA; *LCPD,* Legg-Calvé-Perthes disease; *SCFE,* slipped capital femoral epiphysis.

LIVEDO RETICULARIS

ICD-10CM #		
	L95.0	Livedoid vasculitis

Emboli (SBE, left atrial myxoma, cholesterol emboli).
Thrombocythemia or polycythemia.
Antiphospholipid antibody syndrome.
Cryoglobulinemia, cryofibrinogenemia.
Leukocytoclastic vasculitis.
SLE, RA, dermatomyositis.
Pancreatitis.

Drugs (quinine, quinidine, amantadine, catecholamines).
Physiologic (cutis marmorata).
Congenital.

LIVER DISEASE, PREGNANCY[86]

ICD-10CM # K75.89 Other specified inflammatory liver diseases

INCIDENTAL TO PREGNANCY

Viral hepatitis.
Alcohol related.
Autoimmune chronic active hepatitis.

RELATED TO PREGNANCY (POSSIBLY INFLUENCED BY HORMONES PRESENT IN PREGNANCY)

Complicated gallstone disease.
Hepatic adenoma.
Focal nodular hyperplasia.
Budd-Chiari syndrome.

SPECIFIC TO PREGNANCY

Severe hyperemesis gravidarum.
Benign intrahepatic cholestasis.
Acute fatty liver of pregnancy.
Preeclampsia (HELLP).

LIVER LESIONS, BENIGN, OFTEN CONFUSED WITH MALIGNANCY

ICD-10CM # K76.1 Chronic passive congestion of liver
K76.89 Other specified diseases of liver

Fatty infiltration.
Adenoma.
Hemangioma.
Cysts.
Flow artifacts.
Focal nodular hyperplasia.
Nonenhanced vessels.

LOWER GI ULCERATIVE LESIONS[22]

ICD-10CM # Varies with specific diagnosis

INFECTIOUS

Epstein-Barr virus.
Human immunodeficiency virus.
Cytomegalovirus.
Herpes simplex.
Herpes zoster.
Syphilis.
Erosive candidiasis.
Mycobacterial infection.
Chancroid.
Lymphogranuloma venereum.

NOT INFECTIOUS

Behçet disease.
Excoriation.
Aphthous (idiopathic) ulcer.
Erythema multiforme.
Carcinoma.

LOW-VOLTAGE ECG

ICD-10CM # R94.31 Abnormal electrocardiogram [ECG] [EKG]

Hypothyroidism.
Obesity.
Pericardial effusion.
Anasarca.
Pleural effusion.
Pneumothorax.
Amyloidosis.
Aortic stenosis.

LUMBAR SPINE, VISCEROGENIC PAIN REFERRED TO LUMBAR SPINE[42*]

ICD-10CM # M54.5 Low back pain

Vascular
Expanding aortic aneurysm.
Genitourinary
Endometriosis.
Tubal pregnancy.
Kidney stone.
Prostatitis.
Gastrointestinal
Pancreatitis.
Peptic ulcers.
Colon cancer.

LUNG CANCER, OCCUPATIONAL CAUSES[36]

ICD-10CM # C34.90 Malignant neoplasm of unspecified part of unspecified bronchus or lung

CAUSES OF OCCUPATIONAL LUNG CANCER

Asbestos	Lagging, insulation
Arsenic	Metal smelting, pesticide manufacture
Beryllium	Electronics, dental prosthetic manufacture
Chromium	Coloring pigment production, electroplating
Nickel	Electroplating
Silica	Grinding, quarrying, sandblasting
Radon	Mining
Uranium	Mining

LUNG DISEASE AND GASTROINTESTINAL AND LIVER INVOLVEMENT[61]

ICD-10CM # Varies with specific diagnosis

*All of these disorders may cause localized low back pain.

ESOPHAGEAL REFLUX

Aspiration pneumonia.
Asthma.
Scleroderma.
Bronchitis.
Bronchiectasis.
Cough.
Pulmonary fibrosis.
Mycobacterial disease.

INFLAMMATORY BOWEL DISEASE

Bronchitis.
Bronchiectasis.
Bronchiolitis.
Colobronchial fistula.
Desquamative interstitial lung disease.
Drug reactions for agents that treat inflammatory bowel disease.
Eosinophilic lung disease.
Interstitial lung disease.
Necrobiotic nodules.
Obstructive lung disease.
Organizing pneumonia.
Reduced diffusing capacity.
Sarcoidosis.
Serositis affecting pleura or pericarditis.
Tracheal stenosis.

LIVER

Alpha1-antitrypsin deficiency.
Chronic active hepatitis.
Hepatopulmonary syndrome.
Portapulmonary hypertension.
Primary biliary cirrhosis.
Hepatosplenomegaly.
  Amyloidosis.
  Collagen vascular disease.
  Eosinophilic granulomatosis.
  Lymphatic interstitial pneumonia.
  Sarcoidosis.

LUNG DISEASE AND RENAL INVOLVEMENT[61]

ICD-10CM # Varies with specific diagnosis

LUNG DISEASE WITH RENAL INVOLVEMENT

Glomerulonephritis
Systemic vasculitis.
Collagen vascular disease.
Antibasement membrane.
Sarcoidosis.
Nephrotic Syndrome
Amyloidosis.
Disseminated Langerhans cell histiocytosis.
Drug-induced lung disease.
Paraneoplastic syndrome.
Post transplantation.
Pulmonary hydatid disease.
Systemic lupus erythematosus.
Vasculitis.
Venous thrombosis.
Renal Mass
Lymphangioleiomyomatosis.
Metastasis neoplasm.
Renal carcinoid.
Tuberous sclerosis.

Granulomatosis with polyangiitis.
Nephrolithiasis
Alveolar proteinosis.
Cystic fibrosis.
Hypercalcemic syndromes.
Osteolysis from mycobacteria or fungi.
Sarcoidosis.
Systemic Hypertension
Collagen vascular disease.
Diffuse alveolar hemorrhage.
Pulmonary renal syndromes.
Neurofibromatosis.
Sleep apnea.

LUNG DISEASE AND SKIN AND SUBCUTANEOUS LESIONS[61]

ICD-10CM # Varies with specific diagnosis

SKIN AND SUBCUTANEOUS LESIONS ASSOCIATED WITH LUNG DISEASE

Skin Lesions
Diffuse pigment change:
- Acanthosis nigricans—lung neoplasm.
- Albinism—Hermansky-Pudlak syndrome.
- Bronze pigmentation—hemosiderosis.
- Gray-brown—Whipple disease.

Cutaneous draining sinus:
- Fungal infections (especially histoplasmosis).
- Mycobacterial infections (especially tuberculosis).
- Neoplasms (especially mesothelial tumors).
- Necrotizing vasculitis.
- Other bacterial infections (especially actinomycosis).

Cutaneous ulcers:
- Beryllium disease.
- Chronic venous insufficiency.
- Fungal infections (especially histoplasmosis).
- Mycobacterial disease.
- Necrotizing vasculitis.
- Parasitic disease.
- Polycythemia.
- Sickle cell disease.
- Tularemia.

Cutaneous vasculitis:
- Behçet syndrome.
- Churg-Strauss syndrome.
- Collagen vascular disease.
- Sarcoidosis.
- Granulomatosis with polyangiitis.

Erythema multiforme:
- Drug reactions.
- Fungi (especially coccidiomycosis).
- Mycoplasma and other infectious agents.
- Neoplasms.
- Exfoliative dermatitis.
- Adverse drug reactions.
- Chemotherapy.
- Disseminated malignancy.
- Graft-versus-host disease.
- Radiation therapy.

Flushing:
- Bronchial carcinoid, pheochromocytoma, other neoplasms.
- Carbon dioxide, cyanide, and other toxins.
- Drugs.
- Foods and vasodilatory substances.
- Hormones.
- Mastocytosis.
- Metabolic states (e.g., hyperthyroidism, fever).

Macular rash:
- Anti-basement membrane disease.
- Café-au-lait spots (neurofibromatosis).
- Coal miner's scars.
- Collagen vascular disease.
- Idiopathic pulmonary fibrosis.
- Rose spots (psittacosis).
- Sarcoidosis.
- Syphilis.
- Viral pneumonia.

Maculopapular rash:
- Amyloidosis.
- Drug-induced lung disease.
- Collagen vascular disease.
- Gaucher disease.
- Kaposi sarcoma.
- Lung neoplasm.
- Lymphomatoid granulomatosis.
- Lymphoma.
- Parasites.
- Sarcoidosis.
- Syphilis.
- Vasculitis.
- Viral pneumonia

Telangiectasia:
- Arteriovenous malformation.
- Ataxia-telangiectasia.
- Carcinoid syndrome.
- Cushing disease.
- Hepatopulmonary syndrome and other chronic liver diseases.
- Hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu).
- Mastocytosis.
- Systemic sclerosis and other collagen vascular diseases.

Urticaria:
- Asthma.
- Drug reactions.
- Cystic fibrosis.
- Exercise-induced urticaria.
- Food allergy.
- Hereditary angioneurotic edema.
- Inhaled antigens.
- Insect bites and stings.
- Infectious agents, such as mycoplasma and helicobacter.
- Mastocytosis.
- Occupational sensitization.
- Parasites.
- Vasculitis.

Nail Changes with Lung Disease
Color changes:
- Cigarette smoking discoloration.
- Splinter hemorrhages.
- Yellow nail syndrome.

Beau lines (any severe illness):
- Dermatomyositis.
- Sarcoidosis.
- Seronegative arthropathies.
- Systemic sclerosis.

Lung Disease with Subcutaneous Involvement
Adenopathy:
- Environmental mycobacteria.
- Fungal infections.
- Human immunodeficiency virus infections.
- Metastatic neoplasm.
- Leukemia.
- Lymphoma.
- Sarcoidosis.
- Tuberculosis.

Calcinosis:
- Dermatomyositis.
- Metastatic osteosarcoma.
- Mixed connective tissue disease.
- Scleroderma.
- Tuberculosis.
- Uremic metastatic calcification.

Erythema induratum (Bazin disease):
- Aortic stenosis.
- Cryoglobulinemia.
- Nodular vasculitis.
- Panniculitis.
- Peripheral neuropathy.
- Takayasu disease.
- Streptococcus infection.
- Tuberculosis and other mycobacterial disease.
- Weber-Christian disease.

Erythema nodosa:
- Neoplasm.
- Other infectious and inflammatory diseases.
- Primary coccidiomycosis, histoplasmosis.
- Primary tuberculosis.
- Psittacosis.
- Sarcoidosis.

Subcutaneous nodules:
- Amyloidosis.
- Neoplasm.
- Neurofibromatosis.
- Rheumatoid arthritis.
- Tuberous sclerosis (angiofibromas).
- von Recklinghausen.
- Weber-Christian disease.

Lung Disease with Salivary Gland Enlargement
Bulimia and aspiration.
Gaucher disease.
Lymphoid interstitial pneumonitis.
Lymphatic carcinoma.
Lymphoma.
Other causes of lymphadenopathy.
Sarcoidosis.
Sjögren disease.

LUNG DISEASE WITH BONE, JOINT, NERVE, AND MUSCLE INVOLVEMENT[61]

ICD-10CM # Varies with specific diagnosis

ARTHRITIS

Ankylosing spondylitis.
Collagen vascular diseases.
Reactive arthritis.
Sarcoidosis.
Systemic vasculitis.
Tuberculosis.

BONE LESIONS
Ankylosing spondylitis.
Blastomycosis and other fungal disease.
Collagen vascular diseases.
Eosinophilic granulomatosis.
Fibrous histiocytoma.
Gaucher disease.
Neoplasm.
Sarcoidosis.
Tuberculosis.

MUSCLE DISEASE
Collagen vascular disease.
L-Tryptophan.
Diabetes insipidus.
Eosinophilic granulomatosis.
Polymyositis.
Sarcoidosis.

NEUROLOGIC DISEASE
Acute inflammatory polyneuropathy.
Amyotrophic lateral sclerosis.
Aspiration.
Botulism.
Lambert-Eaton syndrome.
Myasthenia gravis.
Organophosphate poisoning.
Polio and postpolio syndrome.
Sarcoidosis.
Churg-Strauss syndrome.
Granulomatosis with polyangiitis.

LUNG TUMORS, BENIGN[77]
ICD-10CM # Varies with specific disorder

COMMON BENIGN TUMORS OF THE LUNG BASED ON CELLS OF ORIGIN
Tumors of Epithelial Origin
Mucous gland adenoma.
Clara cell adenoma.
Mucous cystadenoma.
Pleomorphic adenoma.
Tumors of Mesenchymal Origin
Hamartoma.
Inflammatory pseudotumor.
Chondroma.
Fibroma.
Benign endobronchial fibrous histiocytoma.
Leiomyoma.
Lipoma.
Lymphatic lesions.
Tumors of Miscellaneous Origin
Nodular pulmonary amyloidosis.
Clear cell tumor (sugar tumor).
Thymoma.
Granular cell tumor.
Teratoma.
Pulmonary paraganglioma.

LUNG VOLUMES IN DIFFUSE LUNG DISEASE[34]
ICD-10CM # Varies with specific disorder

LARGE LUNG VOLUMES
Emphysema.
Chronic asthma.
Diffuse bronchiolitis obliterans.
Highly trained athletes.
Lymphangioleiomyomatosis.

SMALL LUNG VOLUMES
End-stage lung fibrosis.
Bilateral diaphragmatic paralysis.
Massive ascites.

NORMAL LUNG VOLUMES
Sarcoidosis.
Langerhans cell histiocytosis.
Neurofibromatosis.
Emphysema with pulmonary fibrosis.

LYMPHADENOPATHY[32]
ICD-10CM # R59.9 Enlarged lymph nodes, unspecified

GENERALIZED
AIDS.
Lymphoma: Hodgkin disease, non-Hodgkin lymphoma.
Leukemias, reticuloendotheliosis.
Infectious mononucleosis, CMV, and other viral infections.
Diffuse skin infection: generalized furunculosis, multiple tick bites.
Parasitic infections: toxoplasmosis, filariasis, leishmaniasis, Chagas disease.
Serum sickness.
Collagen vascular diseases (RA, SLE).
Dengue (arbovirus infection).
Sarcoidosis and other granulomatous diseases.
Drugs: INH, hydantoin derivatives, antithyroid and antileprosy drugs.
Secondary syphilis.
Hyperthyroidism, lipid-storage diseases.

LOCALIZED
Cervical Nodes
Infections of the head, neck, ears, sinuses, scalp, pharynx.
Mononucleosis.
Lymphoma.
TB.
Malignancy of head and neck.
Rubella.
Scalene/Supraclavicular Nodes
Lymphoma.
Lung neoplasm.
Bacterial or fungal infection of thorax or retroperitoneum.
GI malignancy.
Axillary Nodes
Infections of hands and arms.
Cat-scratch disease.
Neoplasm (lymphoma, melanoma, breast carcinoma).
Brucellosis.
Epitrochlear Nodes
Infections of the hand.
Lymphoma.
Tularemia.
Sarcoidosis, secondary syphilis (usually bilateral).
Inguinal Nodes
Infections of leg or foot, folliculitis (pubic hair).
LGV, syphilis.
Lymphoma.
Pelvic malignancy.
Pasteurella pestis.
Hilar Nodes
Sarcoidosis.
TB.
Lung carcinoma.
Fungal infections, systemic.
Mediastinal Nodes
Sarcoidosis.
Lymphoma.
Lung neoplasm.
TB.
Mononucleosis.
Histoplasmosis.
Abdominal/Retroperitoneal Nodes
Lymphoma.
TB.
Neoplasm (ovary, testes, prostate, and other malignancies).

LYMPHANGITIS[58]
ICD-10CM # I89.1 Lymphangitis

Acute:
- Group A streptococci.
- *Staphylococcus aureus.*
- *Pasteurella multocida.*

Chronic:
- *Sporothrix schenckii* (sporotrichosis).
- *Mycobacterium marinum* (swimming pool granuloma).
- *Mycobacterium kansasii.*
- *Nocardia brasiliensis.*
- *W. bancrofti.*

LYMPHEDEMA[47]
ICD-10CM # i89.0 Lymphedema, not elsewhere classified
I97.2 Postmastectomy lymphedema syndrome
Q82.0 Hereditary lymphedema

CLASSIFICATION OF LYMPHEDEMA
Primary lymphedema
Congenital lymphedema (Milroy disease).
Lymphedema praecox.
Lymphedema tarda.
Syndromes associated with primary lymphedema
Yellow nail syndrome.
Turner syndrome.
Noonan syndrome.
Pes cavus.
Phakomatosis pigmentovascularis.
Distichiasis-lymphedema.
Emberger syndrome.
WILD syndrome.
Hypotrichosis-telangiectasia-lymphedema syndrome.
Cutaneous disorders sometimes associated with primary lymphedema
Yellow nails.

Hemangiomas.
Xanthomatosis and chylous lymphedema.
Congenital absence of nails.
Secondary lymphedema
Postmastectomy lymphedema.
Melphalan isolated limb perfusion.
Malignant occlusion with obstruction.
Extrinsic pressure.
Factitial lymphedema.
Postradiation therapy.
Following recurrent lymphangitis/cellulitis.
Lymphedema of upper limb in recurrent eczema.
Granulomatous disease.
Rosaceous lymphedema.
Primary amyloidosis.
Complications of lymphedema
Cellulitis of lymphedema.
Elephantiasis nostra verrucosa.
Ulceration.
Lymphangiosarcoma.

LYMPHOCYTOSIS, ATYPICAL[58]

ICD-10CM # D72.89 Other specified disorders of white blood cells

Epstein-Barr virus primary infection (infectious mononucleosis).
Cytomegalovirus primary infection (heterophile-negative mono).
Human herpesvirus 6 primary infection (roseola).
Primary HIV infection.
Toxoplasmosis.
Acute viral hepatitis.
Rubella, mumps.
Drug reactions (e.g., phenytoin, sulfa).

MACROTHROMBOCYTOPENIA, INHERITED[45]

ICD-10CM # Varies with specific disorder

Bernard-Soulier syndrome.
MHY9-related disorders:
May-Hegglin anomaly.
Sebastian syndrome.
Fechtner syndrome.
Epstein syndrome.
Gray platelet syndrome.
Montreal platelet syndrome.
Mediterranean macrothrombocytopenia.
Mediterranean stomatocytosis/macrothrombocytemia.
GATA1 mutations.
Sialyl-Lewis-S antigen deficiency.
Paris-Trousseau syndrome.
Platelet-type von Willebrand disease.

MACULAR CRYSTALS[12]

ICD-10CM # Varies with specific diagnosis

OTHER CAUSES OF MACULAR CRYSTALS

Primary hyperoxaluria.
Bietti corneoretinal crystalline dystrophy.
Cystinosis.
Sjögren–Larsson syndrome.
Gyrate atrophy.
Acquired parafoveal telangiectasis.
Talc-corn starch emboli.
West African crystalline maculopathy.

MADAROSIS[12]

ICD-10CM # H02.729 Madarosis of unspecified eye, unspecified eyelid and periocular area

CAUSES OF MADAROSIS

Local
Chronic anterior lid margin disease.
Infiltrating lid tumors.
Burns.
Radiotherapy or cryotherapy of lid tumors.
Skin disorders
Generalized alopecia.
Psoriasis.
Systemic diseases.
Myxoedema.
Systemic lupus erythematosus.
Acquired syphilis.
Lepromatous leprosy.
Following removal
Procedures for trichiasis.
Trichotillomania (psychiatric disorder of hair removal).

MALABSORPTION[86]

ICD-10CM # K90.89 Other intestinal malabsorption

CAUSES OF MALABSORPTION

More Common
Celiac disease.
Chronic pancreatitis.
Post gastrectomy.
Crohn disease.
Small bowel resection.
Small intestinal bacterial overgrowth.
Lactase deficiency.
Less Common
AIDS (*Mycobacterium avium intracellulare*, AIDS enteropathy).
Whipple disease.
Intestinal lymphoma.
Immunoproliferative small intestinal disease (alpha heavy chain disease).
Radiation enteritis.
Collagenous sprue.
Tropical sprue.
Non-granulomatous ulcerative jejunoileitis.
Eosinophilic gastroenteritis.
Amyloidosis.
Zollinger-Ellison syndrome.
Intestinal lymphangiectasia.
Systemic mastocytosis.
Chronic mesenteric ischemia.
Abetalipoproteinemia (autosomal recessive).

MALABSORPTION SYNDROME IN TROPICS[26]

ICD-10CM # K90.89 Other intestinal malabsorption

CAUSES OF MALABSORPTION SYNDROME IN THE TROPICS

SIBO
Following ulcer surgery.
Secondary to intestinal TB and Crohn disease.
Infections
Bacteria
Mycobacterium avium intracellulare complex.
Mycobacterium tuberculosis.
Helminths
Paracapillaria philippinensis.
Strongyloides stercoralis.
Protozoa
Cryptosporidium parvum.
Cyclospora cayetanensis.
Encephalitozoon intestinalis.
Enterocytozoon bieneusi.
Giardia lamblia.
Isospora belli.
Leishmania donovani.
Lymphatic Obstruction
Intestinal lymphangiectasia.
Mucosal Diseases
Autoimmune enteropathy.
Celiac disease.
Eosinophilic gastroenteritis.
HIV enteropathy.
Immunoproliferative small intestinal disease.
Intestinal lymphoma.
Primary immunodeficiencies.
Tropical sprue.
Neonatal Diseases
Microvillus inclusion disease.
Tufting enteropathy.
Pancreatic Insufficiency
Alcoholic pancreatitis.
CF.
Tropical pancreatitis.
Specific Transport Disorders
Abetalipoproteinemia.
Fructose malabsorption.
Glucose-galactose malabsorption.
Hypolactasia.
Sucrose intolerance.

MALNUTRITION, CAUSES IN EARLY LIFE[53]

ICD-10CM # E46 Unspecified protein-energy malnutrition

0 TO 6 MO

Breastfeeding difficulties.
Improper formula preparation.
Impaired parent/child interaction.
Congenital syndromes.
Prenatal infections or teratogenic exposures.
Poor feeding (sucking, swallowing) or feeding refusal (aversion).
Maternal psychological disorder (depression or attachment disorder).
Congenital heart disease.
Cystic fibrosis.
Neurologic abnormalities.
Child neglect.
Recurrent infections.

Hemangiomas.
Xanthomatosis and chylous lymphedema.
Congenital absence of nails.
Secondary lymphedema
Postmastectomy lymphedema.
Melphalan isolated limb perfusion.
Malignant occlusion with obstruction.
Extrinsic pressure.
Factitial lymphedema.
Postradiation therapy.
Following recurrent lymphangitis/cellulitis.
Lymphedema of upper limb in recurrent eczema.
Granulomatous disease.
Rosaceous lymphedema.
Primary amyloidosis.
Complications of lymphedema
Cellulitis of lymphedema.
Elephantiasis nostra verrucosa.
Ulceration.
Lymphangiosarcoma.

LYMPHOCYTOSIS, ATYPICAL[58]

ICD-10CM # D72.89 Other specified disorders of white blood cells

Epstein-Barr virus primary infection (infectious mononucleosis).
Cytomegalovirus primary infection (heterophile-negative mono).
Human herpesvirus 6 primary infection (roseola).
Primary HIV infection.
Toxoplasmosis.
Acute viral hepatitis.
Rubella, mumps.
Drug reactions (e.g., phenytoin, sulfa).

MACROTHROMBOCYTOPENIA, INHERITED[45]

ICD-10CM # Varies with specific disorder

Bernard-Soulier syndrome.
MHY9-related disorders:
May-Hegglin anomaly.
Sebastian syndrome.
Fechtner syndrome.
Epstein syndrome.
Gray platelet syndrome.
Montreal platelet syndrome.
Mediterranean macrothrombocytopenia.
Mediterranean stomatocytosis/macrothrombocytemia.
GATA1 mutations.
Sialyl-Lewis-S antigen deficiency.
Paris-Trousseau syndrome.
Platelet-type von Willebrand disease.

MACULAR CRYSTALS[12]

ICD-10CM # Varies with specific diagnosis

OTHER CAUSES OF MACULAR CRYSTALS

Primary hyperoxaluria.
Bietti corneoretinal crystalline dystrophy.
Cystinosis.
Sjögren–Larsson syndrome.
Gyrate atrophy.
Acquired parafoveal telangiectasis.
Talc-corn starch emboli.
West African crystalline maculopathy.

MADAROSIS[12]

ICD-10CM # H02.729 Madarosis of unspecified eye, unspecified eyelid and periocular area

CAUSES OF MADAROSIS

Local
Chronic anterior lid margin disease.
Infiltrating lid tumors.
Burns.
Radiotherapy or cryotherapy of lid tumors.
Skin disorders
Generalized alopecia.
Psoriasis.
Systemic diseases.
Myxoedema.
Systemic lupus erythematosus.
Acquired syphilis.
Lepromatous leprosy.
Following removal
Procedures for trichiasis.
Trichotillomania (psychiatric disorder of hair removal).

MALABSORPTION[86]

ICD-10CM # K90.89 Other intestinal malabsorption

CAUSES OF MALABSORPTION

More Common
Celiac disease.
Chronic pancreatitis.
Post gastrectomy.
Crohn disease.
Small bowel resection.
Small intestinal bacterial overgrowth.
Lactase deficiency.
Less Common
AIDS (*Mycobacterium avium intracellulare*, AIDS enteropathy).
Whipple disease.
Intestinal lymphoma.
Immunoproliferative small intestinal disease (alpha heavy chain disease).
Radiation enteritis.
Collagenous sprue.
Tropical sprue.
Non-granulomatous ulcerative jejunoileitis.
Eosinophilic gastroenteritis.
Amyloidosis.
Zollinger-Ellison syndrome.
Intestinal lymphangiectasia.
Systemic mastocytosis.
Chronic mesenteric ischemia.
Abetalipoproteinemia (autosomal recessive).

MALABSORPTION SYNDROME IN TROPICS[26]

ICD-10CM # K90.89 Other intestinal malabsorption

CAUSES OF MALABSORPTION SYNDROME IN THE TROPICS

SIBO
Following ulcer surgery.
Secondary to intestinal TB and Crohn disease.
Infections
Bacteria
Mycobacterium avium intracellulare complex.
Mycobacterium tuberculosis.
Helminths
Paracapillaria philippinensis.
Strongyloides stercoralis.
Protozoa
Cryptosporidium parvum.
Cyclospora cayetanensis.
Encephalitozoon intestinalis.
Enterocytozoon bieneusi.
Giardia lamblia.
Isospora belli.
Leishmania donovani.
Lymphatic Obstruction
Intestinal lymphangiectasia.
Mucosal Diseases
Autoimmune enteropathy.
Celiac disease.
Eosinophilic gastroenteritis.
HIV enteropathy.
Immunoproliferative small intestinal disease.
Intestinal lymphoma.
Primary immunodeficiencies.
Tropical sprue.
Neonatal Diseases
Microvillus inclusion disease.
Tufting enteropathy.
Pancreatic Insufficiency
Alcoholic pancreatitis.
CF.
Tropical pancreatitis.
Specific Transport Disorders
Abetalipoproteinemia.
Fructose malabsorption.
Glucose-galactose malabsorption.
Hypolactasia.
Sucrose intolerance.

MALNUTRITION, CAUSES IN EARLY LIFE[53]

ICD-10CM # E46 Unspecified protein-energy malnutrition

0 TO 6 MO

Breastfeeding difficulties.
Improper formula preparation.
Impaired parent/child interaction.
Congenital syndromes.
Prenatal infections or teratogenic exposures.
Poor feeding (sucking, swallowing) or feeding refusal (aversion).
Maternal psychological disorder (depression or attachment disorder).
Congenital heart disease.
Cystic fibrosis.
Neurologic abnormalities.
Child neglect.
Recurrent infections.

6 TO 12 MO

Celiac disease.
Food intolerance.
Child neglect.
Delayed introduction of age-appropriate foods or poor transition to food.
Recurrent infections.
Food allergy.

AFTER INFANCY

Acquired chronic diseases.
Highly distractible child.
Inappropriate mealtime environment.
Inappropriate diet (e.g., excessive juice consumption, avoidance of high-calorie foods).
Recurrent infections.

MEDIASTINAL COMPARTMENTS, ANATOMY AND PATHOLOGY[91]

ICD-10CM # Varies with specific disorder

ANTERIOR

Normal Structures
Lymph nodes.
Connective tissue.
Thymus (remnant in adults).
Masses
Thymoma.
Germ cell neoplasm.
Lymphoma.
Thyroid enlargement (intrathoracic goiter).
Other tumors.

MIDDLE

Normal Structures
Pericardium.
Heart.
Vessels: ascending aorta, venae cavae, main pulmonary arteries.
Trachea.
Lymph nodes.
Nerves: phrenic, upper vagus.
Masses
Carcinoma.
Lymphoma.
Pericardial cyst.
Bronchogenic cyst.
Benign lymph node enlargement (granulomatous disease).

POSTERIOR

Normal Structures
Vessels: descending aorta.
Esophagus.
Vertebral column.
Nerves: sympathetic chain, lower vagus.
Lymph nodes.
Connective tissue.
Masses
Neurogenic tumor.
Diaphragmatic hernia.

MEDIASTINAL MASSES OR WIDENING ON CHEST X-RAY

ICD-10CM # R59.9 Enlarged lymph nodes, unspecified
J98.5 Diseases of mediastinum, not elsewhere classified

Lymphoma: Hodgkin disease and non-Hodgkin lymphoma.
Sarcoidosis.
Vascular: aortic aneurysm, ectasia, or tortuosity of aorta or bronchocephalic vessels.
Carcinoma: lungs, esophagus.
Esophageal diverticula.
Hiatal hernia.
Achalasia.
Prominent pulmonary outflow tract: pulmonary hypertension, pulmonary embolism, right-to-left shunts.
Trauma: mediastinal hemorrhage.
Pneumomediastinum.
Lymphadenopathy caused by silicosis and other pneumoconioses.
Leukemias.
Infections: TB, viral (rare), *Mycoplasma* (rare), fungal, tularemia.
Substernal thyroid.
Thymoma.
Teratoma.
Bronchogenic cyst.
Pericardial cyst.
Neurofibroma, neurosarcoma, ganglioneuroma.

MEDIASTINAL MASSES, SITES OF ORIGIN[89]

ICD-10CM # Varies with specific diagnosis

DIFFERENTIAL DIAGNOSIS OF MEDIASTINAL MASSES BASED ON COMMON SITES OF ORIGIN

Prevascular space (anterior mediastinum)
Thymic masses.
Thymoma.
Thymic carcinoma.
Thymic neuroendocrine tumor.
Thymolipoma.
Thymic cyst.
Thymic hyperplasia.
Thymic lymphoma.
Germ cell tumors.
Teratoma and dermoid cyst.
Seminoma.
Nonseminomatous germ cell tumors.
Thyroid abnormalities (goiter and neoplasm).
Parathyroid tumor or hyperplasia.
Lymph node masses (particularly Hodgkin lymphoma).
Vascular abnormalities (aorta and great vessels).
Mesenchymal abnormalities (e.g., lipomatosis, lipoma).
Foregut cyst.
Lymphangioma.
Hemangioma.
Retrosternal space (anterior mediastinum)
Lymph node masses.
Pretracheal space (middle mediastinum)
Lymph node masses.
Lung carcinoma.
Sarcoidosis.
Lymphoma (particularly Hodgkin disease).
Metastases.
Infections (e.g., tuberculosis).
Foregut cyst.
Tracheal tumor.
Mesenchymal masses (e.g., lipomatosis, lipoma).
Thyroid abnormalities.
Vascular abnormalities (aorta and great vessels).
Lymphangioma and hemangioma.
Aortopulmonary window (middle mediastinum)
Lymph node masses.
Lung carcinoma.
Sarcoidosis.
Lymphoma.
Metastases.
Infections (e.g., tuberculosis).
Mesenchymal masses (e.g., lipomatosis, lipoma).
Vascular abnormalities (aorta or pulmonary artery).
Chemodectoma.
Foregut cyst.
Subcarinal space and azygoesophageal recess (middle mediastinum)
Lymph node masses.
Lung carcinoma.
Sarcoidosis.
Lymphoma.
Metastases.
Infections (e.g., tuberculosis).
Foregut cyst.
Dilated azygos vein.
Esophageal masses.
Varices.
Hernia.
Paravertebral masses (posterior mediastinum)
Neurogenic tumor.
Nerve sheath tumors.
Sympathetic ganglia tumors.
Paraganglioma.
Meningocele.
Foregut cyst.
Neurenteric cyst.
Thoracic spine abnormalities.
Extramedullary hematopoiesis.
Fluid collections and pseudocyst.
Vascular abnormalities.
Hernias.
Esophageal masses.
Varices.
Mesenchymal masses (e.g., lipomatosis, lipoma).
Lymph node masses.
Lymphoma (particularly non-Hodgkin).
Metastases.

Dilated azygos or hemiazygos vein.
Hernia.
Lymphangioma and hemangioma.
Thymic mass or germ cell tumor.
Anterior cardiophrenic angle masses.
Lymph node masses (particularly lymphoma and metastases).
Pericardial cyst.
Fat pad.
Morgagni hernia.
Thymic masses.
Germ cell tumors.

MEDIASTINITIS, ACUTE[58]

ICD-10CM # J98.5 Diseases of mediastinum, not elsewhere classified

Esophageal perforation.
Iatrogenic.
EGD, esophageal dilation, esophageal variceal sclerotherapy, nasogastric tube, Sengstaken-Blackmore tube, endotracheal intubation, esophageal surgery, paraesophageal surgery, transesophageal echocardiography, anterior stabilization of cervical vertebral bodies.
Swallowed foreign bodies.
Trauma.
Spontaneous perforation (e.g., emesis, carcinoma).
Head and neck infections (e.g., tonsillitis, pharyngitis, parotitis, epiglottitis, odontogenic).
Infections originating at another site (e.g., TB, pneumonia, pancreatitis, osteomyelitis of sternum, clavicle, ribs).
Cardiothoracic surgery (median sternotomy) (e.g., CABG, valve replacement, other types of cardiothoracic surgery).

MELANONYCHIA

ICD-10CM # NEC L81.4 Melanin hyperpigmentation

Pregnancy.
Trauma.
Medications (e.g., AZT, 5-fluorouracil, doxorubicin, psoralens).
Nail matrix nevus.
HIV infection.
Onychomycosis.
Melanocyte hyperplasia.
Verrucae.
Pustular psoriasis.
Lichen planus.
Basal cell carcinoma.
Nail matrix melanoma.
Subungual keratosis.
Addison disease.
Bowen disease.

MEMORY LOSS SYMPTOMS, ELDERLY PATIENTS

ICD-10CM # R41.2 Retrograde amnesia

Age-related mild cognitive impairment.
Depression (pseudodementia).
Medications (e.g., anticholinergics, sedatives).
Hypothyroidism.
Chronic hypoxia.
Cerebrovascular infarcts.
Alzheimer disease.
Hepatic disease.
Chronic renal failure.
Hyperthyroidism.
Frontotemporal dementia.
Lewy body dementia.

MENINGITIS, CHRONIC[58]

ICD-10CM # G03.1 Chronic meningitis

TB.
Fungal CNS infection.
Tertiary syphilis.
CNS neoplasm.
Metabolic encephalopathies.
Multiple sclerosis.
Chronic subdural hematoma.
SLE cerebritis.
Encephalitides.
Sarcoidosis.
NSAIDs.
Behçet syndrome.
Anatomic defects (traumatic, congenital, postoperative).
Granulomatous angiitis.

MENINGITIS, RECURRENT[58]

ICD-10CM # G03.2 Benign recurrent meningitis [Mollaret]

Drug induced (with rechallenge).
Parameningeal focus.
  Infection (sinusitis, mastoiditis, osteomyelitis, brain abscess).
  Tumor (epidermoid cyst, craniopharyngioma).
Posttraumatic (bacterial).
Mollaret meningitis.
SLE.
Herpes simplex virus.

MENTAL STATUS CHANGES AND COMA[7]

ICD-10CM # R41.82 Altered mental status, unspecified

METABOLIC/SYSTEMIC ETIOLOGY OF ALTERED MENTAL STATUS AND COMA

Hypoxia
Severe pulmonary disease (hypoventilation).
Severe anemia.
Environmental/toxin:
Methemoglobinemia:
  Cyanide.
  Carbon monoxide.
  Decreased atmospheric oxygen (high altitude).
  Near-drowning.
Disorders of Glucose
Hypoglycemia:
  Chronic alcohol abuse and liver disease.
  Excessive use of insulin or other hypoglycemic agents.
  Insulinoma.
Hyperglycemia:
  Diabetic ketoacidosis.
  Nonketotic hyperosmolar coma.
Decreased Cerebral Blood Flow
Hypovolemic shock.
Cardiac:
  Vasovagal syncope.
  Arrhythmias.
  Myocardial infarction.
  Valvular disorders.
  Congestive heart failure.
  Pericardial effusion/tamponade.
  Myocarditis.
Infectious:
  Septic shock.
  Bacterial meningitis.
Vascular/hematologic:
  Hypertensive encephalopathy.
  Pseudotumor cerebri.
  Hyperviscosity (sickle cell, polycythemia).
  Hyperventilation.
  Cerebral lupus vasculitis.
  Thrombotic thrombocytopenic purpura.
  Disseminated intravascular coagulation.
Metabolic Cofactor Deficiency
Thiamine (Wernicke-Korsakoff syndrome).
Pyridoxine (isoniazid overdose).
Folic acid (chronic alcohol abuse).
Cyanocobalamin.
Niacin.
Electrolyte/pH Disturbances
Acidosis/alkalosis.
Hypernatremia/hyponatremia.[26]
Hypercalcemia/hypocalcemia.
Hypophosphatemia.
Hypermagnesemia/hypomagnesemia.
Endocrine Disorders
Myxedema coma, thyrotoxicosis.
Hypopituitarism.
Addison disease (primary or secondary).
Cushing disease.
Pheochromocytoma.
Hyperparathyroidism/hypoparathyroidism.
Endogenous Toxins
Hyperammonemia (liver failure).
Uremia (renal disease).
Carbon dioxide narcosis (pulmonary disease).
Porphyria.
Exogenous Toxins
Alcohols:
  Ethanol, isopropyl alcohol, methanol, ethylene glycol.
Acid poisons:
  Salicylates.
  Paraldehyde.
  Ammonium chloride.
Antidepressant medications:
  Lithium.
  Tricyclic antidepressants (TCAs).
  Selective serotonin reuptake inhibitors (SSRIs).
  Monamine oxidase inhibitors (MAOIs).
Stimulants:
  Amphetamines/methamphetamines.
  Cocaine.
  Over-the-counter sympathomimetics.
Narcotics/opiates:
  Morphine.
  Heroin.

[26] Can be associated with dilution of formula in infant feeding.

Codeine, oxycodone, meperidine, hydrocodone.
Methadone.
Fentanyl.
Propoxyphene.
Sedative-hypnotics:
Benzodiazepines.
Barbiturates.
Rohypnol.
Bromide.
Hallucinogens:
Lysergic acid diethylamide (LSD).
Marijuana.
Mescaline, peyote.
Mushrooms.
Phencyclidine (PCP).
Herbs/plants:
Aconite.
Jimson weed.
Morning glory.
Volatile substances:
Hydrocarbons (gasoline, butane, toluene, benzene, chloroform).
Nitrites.
Anesthetic agents (nitrous oxide, ether).
Other:
γ-Hydroxybutyrate (GHB).
Ketamine.
Penicillin.
Cardiac glycosides.
Anticonvulsants.
Steroids.
Heavy metals.
Cimetidine.
Organophosphates.

Disorders of Temperature Regulation/ Environmental

Hypothermia.
Heat stroke.
Malignant hyperthermia.
Neuroleptic malignant syndrome.
High-altitude cerebral edema (HACE).
Dysbarism.

Primary Glial or Neuronal Disorders

Adrenoleukodystrophy.
Creutzfeldt-Jakob disease.
Progressive multifocal leukoencephalopathy.
Marchiafava-Bignami disease.
Gliomatosis cerebri.
Central pontine myelinolysis.

Other Disorders of Unknown Etiology

Seizures.
Postictal states.
Reye syndrome.[27]
Intussusception.

[27] Prominent in the pediatric population.

MENTAL STATUS CHANGES AND COMA, STRUCTURAL CAUSES[1]

ICD-10CM # R40.1 Stupor

COMMON AGE-RELATED CAUSES OF ALTERED MENTAL STATUS AND COMA

Infant

Infection.
Trauma, abuse.
Metabolic.

Child

Toxic ingestion.

Adolescent, Young Adult

Toxic ingestion.
Recreational drug use.
Trauma.

Elderly

Medication changes.
Over-the-counter medications.
Infection.
Alterations in living environment.
Stroke.
Trauma.

MENTAL STATUS CHANGES AND COMA, METABOLIC AND SYSTEMIC CAUSES

ICD-10CM # F05.9 Delirium, unspecified

METABOLIC AND SYSTEMIC CAUSES OF ALTERED MENTAL STATUS AND COMA

Hypoxia, Hypercapnia

Severe pulmonary disease (hypoventilation).
Severe anemia.
Environmental, toxic.
Methemoglobinemia.
Cyanide.
Carbon monoxide.
Decreased atmospheric oxygen (high altitude).
Near-drowning.

Glucose Disorders

Hypoglycemia:
Chronic alcohol abuse and liver disease.
Excessive dosage of insulin or other hypoglycemic agents.
Insulinoma.
Hyperglycemia:
Diabetic ketoacidosis.
Nonketotic hyperosmolar coma.

Decreased Cerebral Blood Flow

Hypovolemic shock.
Cardiac:
Vasovagal syncope.
Arrhythmias.
Myocardial infarction.
Valvular disorders.
Congestive heart failure.
Pericardial effusion, tamponade.
Myocarditis.
Infectious:
Septic shock.
Bacterial meningitis.
Vascular, hematologic
Hypertensive encephalopathy.
Pseudotumor cerebri.
Hyperviscosity (sickle cell, polycythemia).
Hyperventilation.
Cerebral vasculitis as a manifestation of systemic lupus erythematosus.
Thrombotic thrombocytopenic purpura.
Disseminated intravascular coagulation.

Metabolic Cofactor Deficiency

Thiamine (Wernicke-Korsakoff syndrome).
Pyridoxine (isoniazid overdose).
Folic acid (chronic alcohol abuse).
Cyanocobalamin.
Niacin.

Electrolyte, pH Disturbances

Acidosis, alkalosis.
Hypernatremia, hyponatremia.[28]
Hypercalcemia, hypocalcemia.
Hypophosphatemia.
Hypermagnesemia, hypomagnesemia.

Endocrine Disorders

Myxedema coma, thyrotoxicosis.
Hypopituitarism.
Addison disease (primary or secondary).
Cushing disease.
Pheochromocytoma.
Hyperparathyroidism, hypoparathyroidism.

Endogenous Toxins

Hyperammonemia (liver failure).
Uremia (renal disease).
Carbon dioxide narcosis (pulmonary disease).
Porphyria.

Exogenous Toxins

Alcohols:
Ethanol, isopropyl alcohol, methanol, ethylene glycol.
Acid poisons:
Salicylates.
Paraldehyde.
Ammonium chloride.
Antidepressant medications:
Lithium.
Tricyclic antidepressants.
Selective serotonin reuptake inhibitors.
Monoamine oxidase inhibitors.
Stimulants:
Amphetamines, methamphetamines.
Cocaine.
Over-the-counter sympathomimetics.
Narcotics, opiates:
Morphine.
Heroin.
Codeine, oxycodone, meperidine, hydrocodone.
Methadone.
Fentanyl.
Propoxyphene.
Sedative-hypnotics:
Benzodiazepines.
Barbiturates.
Rohypnol.
Bromide.
Hallucinogens:
Lysergic acid diethylamide.
Marijuana.
Mescaline, peyote.
Mushrooms.
Phencyclidine.
Herbs, plants:
Aconite.
Jimsonweed.
Morning glory.
Volatile substances:
Hydrocarbons (gasoline, butane, toluene, benzene, chloroform).
Nitrites.
Anesthetic agents (nitrous oxide, ether).

[28] Can be associated with dilution of formula in infant feeding.

Other:
- γ-Hydroxybutyrate.
- Ketamine.
- Penicillin.
- Cardiac glycosides.
- Anticonvulsants.
- Steroids.
- Heavy metals.
- Cimetidine.
- Organophosphates.

Disorders of Temperature Regulation, Environmental

Hypothermia.
Heat stroke.
Malignant hyperthermia.
Neuroleptic malignant syndrome.
High-altitude cerebral edema.
Dysbarism.

Primary Glial or Neuronal Disorders

Adrenoleukodystrophy.
Creutzfeldt-Jakob disease.
Progressive multifocal leukoencephalopathy.
Marchiafava-Bignami disease.
Gliomatosis cerebri.
Central pontine myelinolysis.

Other Disorders with Unknown Etiology

Seizures.
Postictal states.
Reye syndrome.
Intussusception.

MESENTERIC ARTERIAL EMBOLISM, ASSOCIATED FACTORS[7]

ICD-10CM #		
	I74.09	Other arterial embolism and thrombosis of abdominal aorta

FACTORS ASSOCIATED WITH MESENTERIC ARTERIAL EMBOLISM

Coronary artery disease:
- Post-myocardial infarction mural thrombi.
- Congestive heart failure.

Valvular heart disease:
- Rheumatic mitral valve disease.
- Nonbacterial endocarditis.

Arrhythmias:
- Chronic atrial fibrillation.

Aortic aneurysms or dissections.
Coronary angiography.

MESENTERIC ISCHEMIA, NONOCCLUSIVE[58]

ICD-10CM #		
	K55.0	Acute vascular disorders of intestine
	K55.1	Chronic vascular disorders of intestine
	S35.8X9A	Unspecified injury of other blood vessels at abdomen, lower back and pelvis level, initial encounter

Cardiovascular disease resulting in low-flow states (CHF, cardiogenic shock, post cardiopulmonary bypass, dysrhythmias).
Septic shock.
Drug induced (cocaine, vasopressors, ergot alkaloid poisoning).

MESENTERIC VENOUS THROMBOSIS[58]

ICD-10CM #		
	I82.91	Chronic embolism and thrombosis of unspecified vein

Hypercoagulable states (protein C or S deficiency, antithrombin III deficiency, Factor V Leyden, malignancy, polycythemia vera, sickle cell disease, homocystinemia, lupus anticoagulant, cardiolipin antibody).
Trauma (operative venous injury, abdominal trauma, postsplenectomy).
Inflammatory conditions (pancreatitis, diverticulitis, appendicitis, cholangitis).
Other: CHF, renal failure, portal hypertension, decompression sickness.

METASTATIC NEOPLASMS

ICD-10CM #		
	C79.51	Secondary malignant neoplasm of bone
	C79.52	Secondary malignant neoplasm of bone marrow
	C79.31	Secondary malignant neoplasm of brain
	C78.7	Secondary malignant neoplasm of liver and intrahepatic bile duct
	C78.00	Secondary malignant neoplasm of unspecified lung

To Bone	To Brain

Breast.	Testis.
Lymphomas.	Stomach.
Bronchus.	Thyroid.
Lung.	Melanoma.
Sarcoma.	
Choriocarcinoma.	
Kidney.	

METHAEMOGLOBINAEMIA, DRUG-INDUCED[44]

ICD-10CM #		
	D74	Methaemoglobinaemia

SUBSTANCES ASSOCIATED WITH METHAEMOGLOBINAEMIA

Acetaminophen (nitrobenzene derivative).
Acetanilide.
Local anesthetics:
- Benzocaine.
- Lidocaine.
- Prilocaine.

Aniline dyes.
Celecoxib.
Dapsone.
Flutamide.
Ifosfamide.
Metoclopramide.
Nitric oxide.
Nitrites:
- Amyl nitrite.
- Isobutyl nitrite.
- Sodium nitrite.
- Nitrates (bacterial conversion to nitrites).

Nitrobenzenes/nitrobenzoates.
Nitroethane (nail polish remover).
Nitrofurans.
Nitroglycerin.
Paraquat/monolinuron.
Phenacetin.
Phenazopyridine (pyridium).
Primaquine.
Rasburicase.
Sulfamethoxazole.

MICROCEPHALY[9]

ICD-10CM #		
	Q02	Microcephaly

PRIMARY (GENETIC)

Familial (autosomal recessive).
Autosomal dominant.
Syndromes:
- Down (21-trisomy).
- Edward (18-trisomy).
- Cri-du-chat (5 p-).
- Cornelia de Lange.
- Rubinstein-Taybi.
- Smith-Lemli-Opitz.

SECONDARY (NONGENETIC)

Radiation.
Congenital infections:
- Cytomegalovirus.
- Rubella.
- Toxoplasmosis.

Drugs:
- Fetal alcohol.
- Fetal hydantoin.
- Meningitis/encephalitis.
- Malnutrition.
- Metabolic.
- Hyperthermia.
- Hypoxic-ischemic encephalopathy.

MICROPENIS[63]

ICD-10CM #		
	N48.89	Other specified disorders of penis
	Q55.62	Hypoplasia of penis

HYPOGONADOTROPIC HYPOGONADISM (HYPOTHALAMIC OR PITUITARY DEFICIENCIES)

Kallmann syndrome: autosomal dominant; associated with hyposmia.
Prader-Willi syndrome: hypotonia, mental retardation, obesity, small hands and feet.
Rud syndrome: hyposomia, ichthyosis, mental retardation.
De Morsier syndrome (septooptic dysplasia): hypopituitarism, hypoplastic optic discs, absent septum pellucidum.

HYPERGONADOTROPIC HYPOGONADISM

Primary testicular defect: disorders of testicular differentiation or inborn errors of testosterone synthesis.
Klinefelter syndrome.
Other X polysomies (i.e., XXXXY, XXXY).
Robinow syndrome: brachymesomelic dwarfism, dysmorphic facies.

PARTIAL ANDROGEN INSENSITIVITY

Idiopathic
Defective morphogenesis of the penis.

MIOSIS

ICD-10CM # H57.03 Miosis

Medications (e.g., morphine, pilocarpine).
Neurosyphilis.
Congenital.
Iritis.
CNS pontine lesion.
CNS infections.
Cavernous sinus thrombosis.
Inflammation/irritation of cornea or conjunctiva.

MONOARTHRITIS, ACUTE

ICD-10CM # M13.10 Monoarthritis, not elsewhere classified, unspecified site

Overuse.
Trauma.
Gout.
Pseudogout.
Osteoarthritis.
Infectious arthritis (e.g., gonococcal, Lyme disease, viral, mycobacteria, fungi).
Osteomyelitis.
Avascular necrosis of bone.
Hemarthrosis.
Bowel disease–associated arthritis.
Bone malignancy.
Psoriatic arthritis.
Juvenile RA.
Sarcoidosis.
Hemoglobinopathies.
Vasculitic syndromes.
Behçet syndrome.
Foreign body synovitis.
Hypertrophic pulmonary osteoarthropathy.
Amyloidosis, familial Mediterranean fever.

MONOCYTOSIS[45]

ICD-10CM # D72.821 Monocytosis (symptomatic)

Inflammatory diseases:
- Autoimmune/granulomatous.
- Systemic lupus erythematosus.
- Rheumatoid arthritis.
- Giant cell arteritis.
- Myositis.
- Polyarteritis.
- Ulcerative colitis.
- Regional enteritis.
- Sarcoidosis.

Infectious diseases:
- Tuberculosis.
- Syphilis.
- Subacute bacterial endocarditis.

Malignant disorders:
- Preleukemia.
- Nonlymphocytic leukemia.
- Histiocytoses.
- Hodgkin disease.
- Non-Hodgkin lymphoma.
- Carcinomas.

Miscellaneous:
- Chronic neutropenia.
- Post splenectomy.

MONONEUROPATHY

ICD-10CM # G58.9 Mononeuropathy, unspecified

Herpes zoster.
Herpes simplex.
Vasculitis.
Trauma, compression.
Diabetes.
Postinfectious or inflammatory.

MONONEUROPATHY, ISOLATED[7]

ICD-10CM # G56.90 Unspecified mononeuropathy of unspecified upper limb

UPPER EXTREMITY

Radial nerve:
- Axilla.
- Humerus.
- Elbow (posterior interosseous neuropathy).
- Wrist (superficial cutaneous radial neuropathy).

Ulnar nerve:
- Axilla.
- Humerus.
- Elbow.
- Condylar groove.
- Cubital tunnel.

Wrist (Guyon canal):
Hand:
- Superficial terminal ulnar neuropathy.
- Deep terminal ulnar neuropathy:
  - Proximal hypothenar.
  - Distal hypothenar.

Median nerve.
Axilla.
Humerus (musculocutaneous mononeuropathy).
Forearm:
- Anterior interosseus.
- Pronator syndrome.

Wrist (carpal tunnel).
Hand (recurrent motor branch).
Suprascapular mononeuropathy:
- Axillary mononeuropathy.

LOWER EXTREMITY

Sciatic nerve.
Femoral nerve:
- Iliacus compartment (proximal).
- Saphenous mononeuropathy (distal).

Lateral femoral cutaneous (meralgia paresthetica).
Peroneal nerve:
- Common peroneal mononeuropathy (fibular head, popliteal fossa).
- Deep peroneal mononeuropathy (anterior compartment).

Tibial nerve:
- Popliteal fossa (proximal).
- Tarsal tunnel (distal).

Sural nerve:
- Popliteal fossa, calf (proximal).
- Fifth metatarsal base (distal).

Plantar nerve:
- Distal to tarsal tunnel.
- Interdigital neuropathies (Morton neuroma).

Obturator mononeuropathy.

MONONEUROPATHY MULTIPLEX[60]

ICD-10CM # G58.9 Mononeuropathy, unspecified

MONONEUROPATHY MULTIPLEX

Vasculitis
Systemic vasculitis:
- Polyarteritis nodosa.
- Rheumatoid arthritis.
- Systemic lupus erythematosus.
- Sjögren syndrome (keratoconjunctivitis sicca).

Nonsystemic vasculitis
Diabetes mellitus
Neoplastic
Paraneoplastic.
Direct infiltration.
Infectious
Lyme disease.
HIV infection.
Sarcoid
Toxic (lead)
Transient (polycythemia vera)
Cryoglobulinemia (hepatitis C)

MONONUCLEOSIS, MONOSPOT NEGATIVE[3]

ICD-10CM # B27.90 Infectious mononucleosis, unspecified without complication

DIFFERENTIAL DIAGNOSIS OF MONOSPOT-NEGATIVE MONONUCLEOSIS

Acute HIV infection.
EBV mononucleosis (particularly in children).
Cytomegalovirus.
Acute toxoplasmosis.
Streptococcal pharyngitis.
Acute hepatitis B infection.

EBV, Epstein-Barr virus; *HIV,* human immunodeficiency virus.

MOVEMENT DISORDER, PEDIATRIC PATIENT[51]

ICD-10CM # G25.9 Extrapyramidal and movement disorder, unspecified

COMMONLY CITED MOVEMENT DISORDERS THAT MAY BEGIN IN CHILDHOOD OR ADOLESCENCE

Early Childhood
Athetosis or choreoathetosis.
Lesch–Nyhan syndrome.*
Childhood
Dopa-responsive dystonia.*
Dystonia associated with *DYT1* gene.*
Myoclonus from subacute sclerosing panencephalitis (SSPE).
Parkinson disease.
Sydenham chorea.
Tourette disorder.*
Withdrawal-emergent dyskinesia.
Adolescence
Essential tremor.*
Huntington disease (juvenile Huntington disease).*
Medication- and drug-induced movements.
Tardive dyskinesias.
Wilson disease.*

MOVEMENT DISORDERS AND COGNITIVE IMPAIRMENT[51]

ICD-10CM # G25.9 Extrapyramidal and movement disorder, unspecified

MOVEMENT DISORDERS ASSOCIATED WITH COGNITIVE IMPAIRMENT

Young Children
Athetosis or choreoathetosis.*
Lesch–Nyhan syndrome.
Rett syndrome.
Older Children and Adolescents
Huntington disease.
Subacute sclerosing panencephalitis.
Wilson disease.
Adults
Creutzfeldt-Jakob disease.†
Huntington disease.
Parkinson disease.

*Genetic transmission.
*Despite incapacitating movements, many choreoathetosis patients have no mental retardation.
†Myoclonus.

MOVEMENT DISORDERS, NEUROLEPTIC-INDUCED[51]

ICD-10CM # G25.70 Drug-induced movement disorder, unspecified

Acute dyskinesias:
  Akathisia.
  Neuroleptic-malignant syndrome.
  Oculogyric crisis and other dystonias.
Tardive dyskinesias:
  Akathisia.
  Dystonia.
  Oral-buccal-lingual dyskinesia.*
  Tics.
  Tremor.
  Stereotypies.
Dose-dependent dyskinesia:
  Parkinsonism.
Withdrawal-emergent dyskinesias.

*Commonly referred to as "tardive dyskinesia."

MULTIVALVULAR HEART DISEASE[95]

ICD-10CM # Varies with specific diagnosis

Acquired
Systemic diseases:
  Infective endocarditis.
  Carcinoid heart disease.
  Systemic lupus erythematosus.
Cardiac diseases:
  Infective endocarditis.
  Rheumatic heart disease.
Degenerative:
  Calcific diseases, increased with age, prior radiation, chronic kidney disease.
Iatrogenic:
  Adverse drug effects: ergot-related antagonists.
  Radiation therapy.
Functional (annulus dilatation), caused by:
  Ischemic heart disease.
  Hypertensive heart disease.
  Chronic arrhythmia.
  Pulmonary hypertension.
  Cardiomyopathy.

Congenital
Connective tissue disorders:
  Marfan syndrome.
  Ehlers-Danlos syndrome.
Other:
  Trisomy 18, 13, and 15.
  Shone syndrome.
  Ochronosis.

Mixed
Multiple conditions may contribute to valve dysfunction, such as:
  Degenerative diseases may lead to associated functional disease.
  Congenital heart disease may predispose to infective endocarditis or degenerative disease.

MUSCLE DISEASE[80]

ICD-10CM # M60.009 Infective myositis, unspecified site

CLASSIFICATION OF MUSCLE DISEASE

Muscular Dystrophies
Duchenne.
Becker.
Limb girdle.
Childhood.
Facioscapulohumeral.
Myotonic Disorders
Dystrophia myotonica.
Myotonica congenita.
Inflammatory
Infective: bacterial, viral, parasitic.
Unknown cause: polymyositis, dermatomyositis, sarcoidosis.
Endocrine
Thyroid disease—hyper- and hypothyroidism.
Cushing disease.
Addison disease.
Hyperparathyroidism.
Metabolic
Glycogen storage diseases.
Periodic paralyses.
Mitochondrial diseases.
Drug-induced
Corticosteroids.
Chloroquine.
Amiodarone.
Penicillamine.
Alcohol.
Zidovudine.
Clofibrate.
Other
Inclusion body myositis.

MUSCLE WEAKNESS

ICD-10CM # M62.9 Disorder of muscle, unspecified

Physical deconditioning.
Impaired cardiac output (e.g., mitral stenosis, mitral regurgitation).
Uremia, liver failure.
Electrolyte abnormalities (hypokalemia, hyperkalemia, hypophosphatemia, hypercalcemia), hypoglycemia.
Drug induced (e.g., statin myopathy).
Muscular dystrophies.
Steroid myopathy.
Alcoholic myopathy.
Myasthenia gravis, Lambert-Eaton syndrome.
Infections (polio, botulism, HIV, hepatitis, diphtheria, tick paralysis, neurosyphilis, brucellosis, TB, trichinosis).
Pernicious anemia, other anemias, beriberi.
Psychiatric illness (depression, somatization syndrome).
Organophosphate or arsenic poisoning.
Inflammatory myopathies (e.g., collagen vascular disease, RA, sarcoidosis).
Endocrinopathies (e.g., adrenal insufficiency, hypothyroidism), diabetic neuropathy.
Other: motor neuron disease, mitochondrial myopathy, l-tryptophan (eosinophilia-myalgia), rhabdomyolysis, glycogen storage disease, lipid storage disease.

MUSCLE WEAKNESS, LOWER MOTOR NEURON VERSUS UPPER MOTOR NEURON

ICD-10CM # M62.9 Disorder of muscle, unspecified

LOWER MOTOR NEURON

Weakness, usually severe.
Marked muscle atrophy.
Fasciculations.
Decreased muscle stretch reflexes.
Clonus not present.
Flaccidity.
No Babinski sign.
Asymmetric and may involve one limb only in the beginning to become generalized as the disease progresses.

UPPER MOTOR NEURON

Weakness, usually less severe.
Minimal disuse muscle atrophy.
No fasciculations.
Increased muscle stretch reflexes.
Clonus may be present.
Spasticity.
Babinski sign.
Often initial impairment of only skilled movements.
In the limbs the following muscles may be the only ones weak or weaker than the others: triceps; wrist and finger extensors; interossei; iliopsoas; hamstrings; and foot dorsiflexors, inverters, and extroverters.

MUSCULOSKELETAL BENIGN TUMORS AND TUMOR-LIKE LESIONS[71]

ICD-10CM # Varies with specific diagnosis

Fibrous dysplasia.
Enchondromatosis.
Osteochondromatosis.
Synovial cysts.
Brown tumors in hyperparathyroidism.
Langerhans cell histiocytosis (eosinophilic granuloma).
Hemangiomatosis.
Bone islands, osteoma (Gardner syndrome).
Fibrous cortical defect, nonossifying fibroma.
Giant cell tumor.
Neurofibromatosis.
Amyloidosis.
Mastocytosis.
SAPHO, chronic multifocal osteomyelitis.

SAPHO, Synovitis, acne, pustulosis, hyperostosis, osteitis.

MUSCULOSKELETAL MALIGNANT TUMORS AND TUMOR-LIKE LESIONS[71]

ICD-10CM # Varies with specific diagnosis

Metastases.
Myeloma.
Angiosarcoma.
Leukemia.
Neuroblastoma.
Ewing sarcoma.
Osteosarcomatosis.
Lymphoma.

MYDRIASIS

ICD-10CM # H57.04 Mydriasis

Coma.
Medications (cocaine, atropine, epinephrine, etc.).
Glaucoma.
Cerebral aneurysm.
Ocular trauma.
Head trauma.
Optic atrophy.
Cerebral neoplasm.
Iridocyclitis.

MYELIN DISORDERS

ICD-10CM # Varies with specific diagnosis

Multiple sclerosis.
Vitamin B_{12} deficiency.
Radiation.
Hypoxia.
Toxicity from carbon monoxide, alcohol, mercury.
Progressive multifocal encephalopathy.
Acute disseminated encephalomyelitis.
Acute hemorrhagic leukoencephalopathy.
Phenylketonuria.
Adrenoleukodystrophy.
Krabbe disease.

MYELITIS[88]

ICD-10CM # G04.91 Myelitis, unspecified
G04.89 Other myelitis

Viral
HIV.
HSV-1 and HSV-2.
VZV.
CMV.
EBV.
WNV.
HTLV.
Bacterial
Mycoplasma pneumoniae.
Borrelia burgdorferi.
Treponema pallidum.
Pyogenic bacteria.
Mycobacterium tuberculosis.
Fungal
Coccidioides immitis.
Actinomyces.
Aspergillus.
Blastomyces dermatitidis.
Histoplasmosis.
Immune-Mediated
Multiple sclerosis.
Neuromyelitis optica.
Connective tissue disorders (neuro-lupus, neuro-Sjögren).
Neurosarcoidosis.
Paraneoplastic.
Noninflammatory Myelopathies
Vitamin B_{12} deficiency.
Folic acid deficiency.
Copper deficiency.
Vitamin E deficiency.
Nitrous oxide toxicity.
Heroin.
Radiation myelopathy.
Traumatic/compressive myelopathy.
Vascular myelopathy.

MYELOPATHY AND MYELITIS[82]

ICD-10CM # M51.9 Unspecified thoracic, thoracolumbar and lumbosacral intervertebral disc disorder
G95.9 Disease of spinal cord, unspecified

INFLAMMATORY

Infectious: spirochetal TB, zoster, rabies, HIV, polio, rickettsial, fungal, parasitic.
Noninfectious: idiopathic transverse myelitis, multiple sclerosis.

TOXIC/METABOLIC

DM, pernicious anemia, chronic liver disease, pellagra, arsenic.

TRAUMA COMPRESSION

Spinal neoplasm, cervical spondylosis, epidural abscess, epidural hematoma.

VASCULAR

AV malformation, SLE, periarteritis nodosa, dissecting aortic aneurysm.

PHYSICAL AGENTS

Electrical injury, irradiation.

NEOPLASTIC

Spinal cord tumors, paraneoplastic myelopathy.

MYOCARDIAL ISCHEMIA[82]

ICD-10CM # I25.5 Ischemic cardiomyopathy
I25.89 Other forms of chronic ischemic heart disease
I25.9 Chronic ischemic heart disease, unspecified
I24.8 Other forms of acute ischemic heart disease

Atherosclerotic obstructive coronary artery disease.
Nonatherosclerotic coronary artery disease:
- Coronary artery spasm.
- Congenital coronary artery anomalies:
  - Anomalous origin of coronary artery from pulmonary artery.
  - Aberrant origin of coronary artery from aorta or another coronary artery.
  - Coronary arteriovenous fistula.
  - Coronary artery aneurysm.

Acquired disorders of coronary arteries:
- Coronary artery embolism.
- Dissection:
  - Surgical.
  - During percutaneous coronary angioplasty.
  - Aortic dissection.
  - Spontaneous (e.g., during pregnancy).

Extrinsic compression:
Tumors.
Granulomas.
Amyloidosis.
Collagen-vascular disease:
Polyarteritis nodosa.
Temporal arteritis.
RA.
SLE.
Scleroderma.
Miscellaneous disorders:
Irradiation.
Trauma.
Kawasaki disease.
Syphilis.
Hereditary disorders:
Pseudoxanthoma elasticum.
Gargoylism.
Progeria.
Homocystinuria.
Primary oxaluria.
"Functional" causes of myocardial ischemia in absence of anatomic coronary artery disease:
Syndrome X.
Hypertrophic cardiomyopathy.
Dilated cardiomyopathy.
Muscle bridge.
Hypertensive heart disease.
Pulmonary hypertension.
Valvular heart disease; aortic stenosis, aortic regurgitation.

MYOCLONUS

ICD-10CM # G25.3 Myoclonus

Physiologic (e.g., exercise or anxiety induced).
Renal failure.
Hepatic failure.
Hyponatremia.
Hypoglycemia or severe hyperglycemia.
Postdialysis.
Epileptic myoclonus.
Postencephalitis.
CNS lesion (stroke, neoplasm).
CNS trauma.
Parkinson disease.
Medications (e.g., tricyclics, L-dopa).
Friedreich ataxia.
Ataxia-telangiectasia.
Wilson disease.
Huntington disease.
Progressive supranuclear palsy.
Heavy metal poisoning.
Benign familial.

MYOCLONUS, DRUG-INDUCED[84]

ICD-10CM # G25.79 Other drug-induced movement disorders

SELECTED AGENTS ASSOCIATED WITH MYOCLONUS

Medications
Antibiotics (β-lactams).
Antidepressants.
Antineoplastics: busulfan, chlorambucil.
Carbamazepine, vigabatrin.
Clozapine.
L-dopa.
Lidocaine.
Lithium.
Lorazepam (preterm infants).
Methaqualone.
Morphine.
Nitroprusside.
Piperazine.
Industrial Toxins
Camphor.
Chlorophenoxy herbicides.
Gasoline.
Biological Toxins
Buckeye (*Aesculus* spp.).
Lupine.
Shellfish (domoic acid poisoning).

MYOCLONUS, PEDIATRIC PATIENT[54]

ICD-10CM # G25.3 Myoclonus

Selected Causes of Myoclonus in Children
Physiologic Causes
Hiccups.
Hypnic jerks (sleep starts).
Nocturnal (sleep) myoclonus.
Developmental Causes
Benign neonatal sleep myoclonus.
Benign myoclonus of early infancy.
Myoclonus with fever.
Storage Diseases
Juvenile Gaucher disease (type III).
Sialidosis type 1 (cherry-red spot–myoclonus).
GM_1 gangliosidosis.
Neuronal ceroid-lipofuscinosis (late infantile).
Inherited Degenerative Diseases
Dentatorubral-pallidoluysian atrophy (DRPLA).
Huntington disease.
Progressive myoclonus ataxia.
Ramsay Hunt syndrome.
Early myoclonic encephalopathy.
Rasmussen encephalitis.
Infectious and Postinfectious Diseases
Meningitis (viral or bacterial).
Encephalitis.
Epstein-Barr virus (EBV).
Coxsackievirus.
Influenza.
Human immunodeficiency virus (HIV).
Acute disseminated encephalomyelitis (ADEM).
Metabolic Causes
Uremia.
Hepatic failure.
Electrolyte disturbances.
Hypoglycemia or hyperglycemia.
Aminoacidurias.
Organic acidurias.
Urea cycle disorders.
POLG1 mutations.
Myoclonic epilepsy with ragged red fibers (MERRF).
Mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS).
Biotinidase deficiency (usually epileptic).
Cobalamin deficiency (infantile).
Leigh syndrome.
Toxic Causes
Psychotropic medications (tricyclic antidepressants, lithium, selective serotonin reuptake inhibitors, monoamine oxidase inhibitors, neuroleptics).
Antibiotics (penicillin, cephalosporins, quinolones).
Antiepileptics (phenytoin, carbamazepine, lamotrigine, gabapentin, benzodiazepines [in infants], vigabatrin).
Opioids.
General anesthetics.
Antineoplastic drugs.
Strychnine, toluene, lead, carbon monoxide, mercury.
Hypoxia
Lance-Adams syndrome.
Functional (Psychogenic) Causes

MYOPATHIC SYNDROMES, DRUG-INDUCED[41]

ICD-10CM # G72.9 Myopathy, unspecified

TYPE OF MYOPATHY

Necrotizing myopathy.
Inflammatory myopathy.
Mitochondrial myopathy.
Hypokalemic myopathy.
Antimicrotubular myopathy.
Lysosomal storage myopathy.
Corticosteroid myopathy.
Others.

DRUGS

HMG-CoA reductase inhibitors (statins), fibrates, alcohol.
Penicillamine, interferon-a, procainamide.
Zidovudine.
Diuretics, laxatives, licorice, amphotericin B, alcohol.
Colchicine, vincristine.
Chloroquine, hydroxychloroquine, quinacrine, amiodarone, perhexiline.
Corticosteroids, especially fluorinated.
Ipecac syrup, emetine.

MYOPATHIES ASSOCIATED WITH REST PAIN[41]

ICD-10CM # G72.9 Myopathy, unspecified

Childhood dermatomyositis.
Hypothyroid myopathy.
Acute alcoholic myopathy.
Drug-induced myopathies.
Infectious myopathies.
Myopathies associated with metabolic bone disease.
Carnitine palmitoyl transferase deficiency.
Rhabdomyolysis from any cause.

MYOPATHIES, HIV ASSOCIATED[27]

ICD-10CM # G72.9 Myopathy, unspecified

HIV-Associated Myopathies	Myopathies Secondary to Antiretrovirals	Others
HIV polymyositis.	Zidovudine myopathy.	Opportunistic infections involving muscle (toxoplasmosis).
Inclusion body myositis.	Toxic mitochondrial myopathies related to other NRTIs.	Tumor infiltrations of skeletal muscle.
Nemaline myopathy.		Rhabdomyolysis.
Diffuse infiltrative lymphocytosis syndrome.	HIV-associated lipodystrophy syndrome.	
HIV wasting syndrome.	Immune reconstitution syndrome related to ART.	
Vasculitic processes.		
Myasthenia gravis and other myasthenic syndromes.		
Chronic fatigue and fibromyalgia.		

ART, Antiretroviral therapy; *NRTIs,* nucleoside reverse transcriptase inhibitors.

MYOPATHIES, INFECTIOUS

ICD-10CM # G72.9 Myopathy, unspecified

HIV.
Viral myositis.
Trichinosis.
Toxoplasmosis.
Cysticercosis.

MYOPATHIES, INFLAMMATORY

ICD-10CM # G72.9 Myopathy, unspecified

SLE, RA.
Sarcoidosis.
Paraneoplastic syndrome.
Polymyositis, dermatomyositis.
Polyarteritis nodosa.
Mixed connective tissue disease.
Scleroderma.
Inclusion body myositis.
Sjögren syndrome.
Cimetidine, d-penicillamine.

MYOPATHIES, METABOLIC[41]

ICD-10CM # G72.9 Myopathy, unspecified

DISORDERED GLYCOGEN METABOLISM

Myophosphorylase deficiency (McArdle disease).
Phosphorylase b kinase deficiency.
Phosphofructokinase deficiency.
Debrancher enzyme deficiency.
Brancher enzyme deficiency.
Phosphoglycerate kinase deficiency.
Phosphoglycerate mutase deficiency.
Lactate dehydrogenase deficiency.
Acid maltase deficiency.
Aldolase deficiency.
β-Enolase deficiency.

DISORDERED LIPID METABOLISM

Carnitine deficiencies.
Carnitine palmitoyltransferase deficiency.
Fatty acid acyl-CoA dehydrogenase deficiencies.

MITOCHONDRIAL MYOPATHIES

Coenzyme Q10 deficiency.
Respiratory chain complex deficiencies.

ENDOCRINE

Acromegaly.
Hypothyroidism.
Hyperthyroidism.
Hyperparathyroidism.
Cushing disease.
Addison disease.
Hyperaldosteronism.

METABOLIC-NUTRITIONAL

Uremia.
Hepatic failure.
Malabsorption.
Periodic paralysis.
Vitamin D deficiency.
Vitamin E deficiency.

ELECTROLYTE DISORDERS

Sodium: hypernatremia and hyponatremia.
Potassium: hyperkalemia and hypokalemia.
Calcium: hypercalcemia and hypocalcemia.
Phosphate: hypophosphatemia.
Magnesium: hypomagnesemia.

MYOPATHIES, TOXIC[3]

ICD-10CM # G72.2 Myopathy due to other toxic agents

Inflammatory: cimetidine, d-penicillamine.
Noninflammatory necrotizing or vacuolar: cholesterol-lowering agents, chloroquine, colchicine.
Acute muscle necrosis and myoglobinuria: cholesterol-lowering drugs, alcohol, cocaine.
Malignant hyperthermia: halothane, ethylene, others; succinylcholine.
Mitochondrial: zidovudine.
Myosin loss: nondepolarizing neuromuscular blocking agents; glucocorticoids.

MYOPATHY, DRUG-INDUCED[42]

ICD-10CM # G72.9 Myopathy, unspecified

DRUGS AND TOXINS THAT MAY INDUCE MYOPATHY

Example	Comments
Cimetidine.	
Chloroquine.	Vacuolar myopathy.
Colchicine.	Vacuolar myopathy.
Emetine.	
Ethanol.	Acute rhabdomyolysis and chronic myopathy.
Glucocorticoids.	Type II fiber atrophy.
Heroin.	
IFN-α.	Dermatomyositis and polymyositis reported.
Penicillamine.	Typical polymyositis. Mitochondrial myopathy.
Statins and fibrates.	Cases of autoimmune necrotizing myopathy, polymyositis, rhabdomyolysis, and noninflammatory myopathies reported.
AntiTNF.	In RA patients existing reports of polymyositis, dermatomyositis and anti–Jo-1–positive myositis during TNF blockade.
Zidovudine (AZT).	
(Many others reported at the case level.)	

AZT, Zidovudine; *IFN,* interferon; *RA,* rheumatoid arthritis; *TNF,* tumor necrosis factor.

MYOSITIS, INFECTIOUS CAUSES[41]

ICD-10CM # M60.009 Infective myositis, unspecified site

VIRAL

Influenza A and B viruses.
Enteroviruses (coxsackieviruses, echoviruses).
Human immunodeficiency virus.
Human T-cell lymphotrophic virus type 1.
Hepatitis B and C viruses.
Cytomegalovirus.
Epstein-Barr virus.
Adenovirus.
Varicella-zoster virus.
Parainfluenza.

PARASITIC

Trichinella species.
Echinococcus species.
Schistosoma species.
Toxoplasma gondii.
Trypanosoma cruzi.
Sarcocystis species.

BACTERIAL

Staphylococcus aureus.
Streptococcus, groups A and B.
Aeromonas hydrophila.
Borrelia burgdorferi.
Clostridium perfringens.
Anaerobic streptococci.
Mycobacterium species.
Rickettsia species.

FUNGAL

Candida species.
Cryptococcus neoformans.
Microsporida.

MYOSITIS, INFLAMMATORY[3]

ICD-10CM #		
	M60.009	Infective myositis, unspecified site
	M60.9	Myositis, unspecified
	M60.10	Interstitial myositis of unspecified site

INFECTIOUS

Viral myositis:
- Retroviruses (HIV, HTLV-I).
- Enteroviruses (echovirus, Coxsackievirus).
- Other viruses (influenza, hepatitis A and B, Epstein-Barr virus).

Bacterial: pyomyositis.
Parasites: trichinosis, cysticercosis.
Fungi: candidiasis.

IDIOPATHIC

Granulomatous myositis (sarcoid, giant cell).
Eosinophilic myositis.
Eosinophilia-myalgia syndrome.

ENDOCRINE/METABOLIC DISORDERS

Hypothyroidism.
Hyperthyroidism.
Hypercortisolism.
Hyperparathyroidism.
Hypoparathyroidism.
Hypocalcemia.
Hypokalemia.

METABOLIC MYOPATHIES

Myophosphorylase deficiency (McArdle disease).
Phosphofructokinase deficiency.
Myoadenylate deaminase deficiency.
Acid maltase deficiency.
Lipid storage diseases.
Acute rhabdomyolysis.

DRUG-INDUCED MYOPATHIES

Alcohol.
d-Penicillamine.
Zidovudine.
Colchicine.
Chloroquine, hydroxychloroquine.
Lipid-lowering agents.
Cyclosporine.
Cocaine, heroin, barbiturates.
Corticosteroids.

NEUROLOGIC DISORDERS

Muscular dystrophies.
Congenital myopathies.
Motor neuron disease.
Guillain-Barré syndrome.
Myasthenia gravis.

NAIL CLUBBING

ICD-10CM #		
	R68.3	Clubbing of nails

COPD.
- Pulmonary malignancy.
- Cirrhosis.
- Inflammatory bowel disease.
- Chronic bronchitis.
- Congenital heart disease.
- Endocarditis.
- AV malformations.
- Asbestosis.
- Trauma.
- Idiopathic.

NAIL, HORIZONTAL WHITE LINES (BEAU LINES)

ICD-10CM #		
	L60.4	Beau lines

Malnutrition.
Idiopathic.
Trauma.
Prolonged systemic illnesses.
Pemphigus.
Raynaud phenomenon.

ICD-10CM #		
	L60.8	Other nail disorders

Tobacco abuse.
Nephrotic syndrome.
Chronic infections (TB, sinusitis).
Bronchiectasis.
Lymphedema.
Raynaud phenomenon.
RA.
Pleural effusions.
Thyroiditis.
Immunodeficiency.

NASAL AND PARANASAL SINUS TUMORS[36]

ICD-10CM #		
	C30.0	Malignant neoplasm of nasal cavity

BENIGN AND MALIGNANT NASAL AND PARANASAL SINUS TUMORS

Epithelial Tumors

BENIGN

Papilloma.
Adenoma.
Inverting papilloma.

MALIGNANT

Squamous carcinoma.
Adenocarcinoma.
Melanoma.
Adenoid cystic carcinoma.
Malignant salivary tumors.

MESENCHYMAL TUMORS

Benign
Osteoma.

FUNGAL

Candida species.
Cryptococcus neoformans.
Microsporida.

MYOSITIS, INFLAMMATORY[3]

ICD-10CM #		
	M60.009	Infective myositis, unspecified site
	M60.9	Myositis, unspecified
	M60.10	Interstitial myositis of unspecified site

INFECTIOUS

Viral myositis:
- Retroviruses (HIV, HTLV-I).
- Enteroviruses (echovirus, Coxsackievirus).
- Other viruses (influenza, hepatitis A and B, Epstein-Barr virus).

Bacterial: pyomyositis.
Parasites: trichinosis, cysticercosis.
Fungi: candidiasis.

IDIOPATHIC

Granulomatous myositis (sarcoid, giant cell).
Eosinophilic myositis.
Eosinophilia-myalgia syndrome.

ENDOCRINE/METABOLIC DISORDERS

Hypothyroidism.
Hyperthyroidism.
Hypercortisolism.
Hyperparathyroidism.
Hypoparathyroidism.
Hypocalcemia.
Hypokalemia.

METABOLIC MYOPATHIES

Myophosphorylase deficiency (McArdle disease).
Phosphofructokinase deficiency.
Myoadenylate deaminase deficiency.
Acid maltase deficiency.
Lipid storage diseases.
Acute rhabdomyolysis.

DRUG-INDUCED MYOPATHIES

Alcohol.
d-Penicillamine.
Zidovudine.
Colchicine.
Chloroquine, hydroxychloroquine.
Lipid-lowering agents.
Cyclosporine.
Cocaine, heroin, barbiturates.
Corticosteroids.

NEUROLOGIC DISORDERS

Muscular dystrophies.
Congenital myopathies.
Motor neuron disease.
Guillain-Barré syndrome.
Myasthenia gravis.

NAIL CLUBBING

ICD-10CM #		
	R68.3	Clubbing of nails

COPD.
- Pulmonary malignancy.
- Cirrhosis.
- Inflammatory bowel disease.
- Chronic bronchitis.
- Congenital heart disease.
- Endocarditis.
- AV malformations.
- Asbestosis.
- Trauma.
- Idiopathic.

NAIL, HORIZONTAL WHITE LINES (BEAU LINES)

Thyroiditis.
Immunodeficiency.

NASAL AND PARANASAL SINUS TUMORS[36]

ICD-10CM #		
	C30.0	Malignant neoplasm of nasal cavity

BENIGN AND MALIGNANT NASAL AND PARANASAL SINUS TUMORS

Epithelial Tumors

BENIGN

Papilloma.
Adenoma.
Inverting papilloma.

MALIGNANT

Squamous carcinoma.
Adenocarcinoma.
Melanoma.
Adenoid cystic carcinoma.
Malignant salivary tumors.

MESENCHYMAL TUMORS

Benign
Osteoma.

Ossifying fibroma complex.
Angiofibroma.
Chondroma.
Malignant
Osteogenic sarcoma.
Fibrosarcoma.
Angiosarcoma.
Chondrosarcoma.
Lymphoma.
Rhabdomyosarcoma.

NASAL MASSES, CONGENITAL[36]

ICD-10CM #	J34.1	Cyst and mucocele of nose and nasal sinus
	J34.89	Other specified disorders of nose and nasal sinuses

Dermoid.
Nasal cerebral heterotopia (glioma).
Frontal meningoencephalocele.
Nasolacrimal duct mucocele.
Nasal hamartoma.
Nasal hemangioma.

NAUSEA AND VOMITING

ICD-10CM #	R11.2	Nausea with vomiting, unspecified

Infections (viral, bacterial).
Intestinal obstruction.
Metabolic (uremia, electrolyte abnormalities, DKA, acidosis, etc.).
Severe pain.
Anxiety, fear.
Psychiatric disorders (bulimia, anorexia nervosa).
Pregnancy.
Medications (NSAIDs, erythromycin, morphine, codeine, aminophylline, chemotherapeutic agents, etc.).
Withdrawal from substance abuse (drugs, alcohol).
Head trauma.
Vestibular or middle ear disease.
Migraine headache.
CNS neoplasms.
Radiation sickness.
PUD.
Carcinoma of GI tract.
Reye syndrome.
Eye disorders.
Abdominal trauma.

NAUSEA AND VOMITING, CAUSES DURING PREGNANCY[30]

ICD-10CM #	R11.2	Nausea with vomiting, unspecified

DIFFERENTIAL DIAGNOSIS OF NAUSEA AND VOMITING DURING PREGNANCY

Nausea and vomiting of pregnancy.
Hyperemesis gravidarum.
Pancreatitis.
Symptomatic cholelithiasis.
Viral hepatitis.
Peptic ulcer disease.
Gastric cancer.
Intestinal obstruction.
Intestinal pseudoobstruction.
Gastroparesis diabeticorum.
Gastritis.
Gastroesophageal reflux disease.
Acute pyelonephritis.
Drug toxicity.
Vagotomy.
Preeclampsia/eclampsia.
Acute fatty liver of pregnancy.
Hemolysis, elevated liver enzymes, and low platelets (HELLP) syndrome.
Anorexia nervosa/bulimia.
Other neuropsychiatric disorders.

NAUSEA AND VOMITING, CHRONIC[26]

ICD-10CM #	R11.2	Nausea with vomiting, unspecified

DIFFERENTIAL DIAGNOSIS OF CHRONIC NAUSEA AND VOMITING

Mechanical GI tract obstruction (pylorus, bile duct, small intestine, colon).
Mucosal inflammation.
Peritoneal irritation.
Carcinomas (e.g., gastric, ovarian, renal, bronchogenic).
Metabolic/endocrine disorders (diabetic mellitus, hypothyroidism, hyperthyroidism, adrenal insufficiency, uremia).
Medications (anticholinergics, narcotics, L-dopa, progesterone, calcium channel blockers, digitalis, NSAIDs, antidysrhythmic agents, lubiprostone, cannabis, metformin, amylin analogs).
Gastroparesis.
Gastric dysrhythmias (tachygastria, bradygastria, mixed).
CNS disorders (tumors, migraine, seizures, stroke, orthostatic intolerance).
Psychogenic disorders (anorexia nervosa, bulimia nervosa).

NECK AND ARM PAIN

ICD-10CM #	M54.2	Cervicalgia
	S46.919A	Strain of unspecified muscle, fascia and tendon at shoulder and upper arm level, unspecified arm, initial encounter

Cervical disk syndrome.
Trauma, musculoskeletal strain.
Rotator cuff syndrome.
Bicipital tendonitis.
Glenohumeral arthritis.
Acromioclavicular arthritis.
Thoracic outlet syndrome.
Pancoast tumor.
Infection (cellulitis, abscess).
Angina pectoris.

NECK MASS[65]

ICD-10CM #	R22.1	Localized swelling, mass and lump, neck

CONGENITAL ANOMALIES

Thyroglossal duct cyst.
Bronchial apparatus anomalies.
Teratomas.
Ranula.
Dermoid cysts.
Hemangioma.
Laryngoceles.
Cystic hygroma.

NONNEOPLASTIC INFLAMMATORY ETIOLOGIES

Folliculitis.
Adenopathy secondary to peritonsillar abscess.
Retropharyngeal or parapharyngeal abscess.
Salivary gland infections.
Viral infections (mononucleosis, HIV, CMV).
TB.
Cat-scratch disease.
Toxoplasmosis.
Actinomyces.
Atypical mycobacterium.
Jugular vein thrombus.

NEOPLASM (PRIMARY OR METASTATIC)

LIPOMA

NECK PAIN[65]

ICD-10CM #	M54.2	Cervicalgia

INFLAMMATORY DISEASES

RA.
Spondyloarthropathies.
Juvenile RA.

NONINFLAMMATORY DISEASE

Cervical osteoarthritis.
Diskogenic neck pain.
Diffuse idiopathic skeletal hyperostosis.
Fibromyalgia or myofascial pain.

INFECTIOUS CAUSES

Meningitis.
Osteomyelitis.
Infectious diskitis.

NEOPLASMS

Primary.
Metastatic.

REFERRED PAIN

Temporomandibular joint pain.
Cardiac pain.
Diaphragmatic irritation.
GI sources (gastric ulcer, gallbladder, pancreas).

NECK PAIN FROM RHEUMATOLOGIC DISORDERS[27]

ICD-10CM #	M54.2	Cervicalgia

Rheumatoid arthritis:
- Without disease of the C1-C2 joint.
- With structural cervical abnormalities: C1-C2 subluxation, C1-C2 facet involvement.

Spondyloarthropathies.
Reactive arthritis.
Psoriatic arthritis.
Enteropathic arthritis.
Polymyalgia rheumatica.
Osteoarthritis.
Fibromyalgia.
Nonspecific musculoskeletal pain.
Miscellaneous spondyloarthropathies.
- Whipple disease.
- Behçet disease.
- Paget disease.
- Acromegaly.
- Ossification of the posterior longitudinal ligament.
- Diffuse idiopathic skeletal hyperostosis.

NECK PAIN, NONMUSCULAR CAUSES[42]

ICD-10CM # M54.2 Cervicalgia

Structure	Condition
Pharynx.	Pharyngitis.
Larynx.	Laryngitis.
	Carcinoma.
Trachea.	Tracheitis.
Thyroid.	Thyroiditis.
Lymph nodes.	Lymphadenitis.
Carotid arteries.	Carotidynia.
	Dissection.
	Inflammation.
Aorta.	Aneurysm.
	Dissection.
Heart.	Angina.
	Infarction.
Pericardium.	Pericarditis.
Diaphragm.	Inflammation by blood, infection.

NECROTIZING PNEUMONIAS[3]

ICD-10CM # J15.8 Pneumonia due to other specified bacteria

COMMON

Tuberculosis.
Staphylococcus.
Gram-negative bacilli.
Anaerobes.
Fungi.
Pneumocystis jirovecii.

RARE

Streptococcus pneumoniae.
Legionella.
Viruses.
Mycoplasma pneumoniae.

NEOPLASTIC LESIONS, LUMBOSACRAL SPINE[42,*]

ICD-10CM # M54.5 Low back pain

*Although these are most common neoplastic lesions of the lumbosacral spine, most occur infrequently.

BENIGN

Osteoid osteoma.
Osteoblastoma.
Osteochondroma.
Giant cell tumor.
Aneurysmal bone cyst.
Hemangioma.
Eosinophilic granuloma.
Sacroiliac lipoma.

MALIGNANT

Multiple myeloma.
Chondrosarcoma.
Chordoma.
Lymphoma.
Skeletal metastases.

SPINAL CORD TUMORS

Extradural metastases.
Intradural–extramedullary:
- Neurofibroma.
- Meningioma.

Intramedullary:
- Ependymoma.
- Astrocytoma.

NEPHRITIC SYNDROME, ACUTE[3]

ICD-10CM # N00.8 Acute nephritic syndrome with other morphologic changes

LOW SERUM COMPLEMENT LEVEL

Acute postinfectious glomerulonephritis.
Membranoproliferative glomerulonephritis.
SLE.
Subacute bacterial endocarditis.
Visceral abscess "shunt" nephritis.
Cryoglobulinemia.

NORMAL SERUM COMPLEMENT LEVEL

IgA nephropathy.
Antiglomerular basement membrane disease.
Polyarteritis nodosa.
Granulomatosis with polyangiitis.
Henoch-Schönlein purpura.
Goodpasture syndrome.

NEPHROCALCINOSIS

ICD-10CM # E83.59 Other disorders of calcium metabolism

Sarcoidosis.
Hyperparathyroidism.
Chronic glomerulonephritis.
Milk-alkali syndrome.
Distal renal tubular acidosis.
Medullary sponge kidney.
Bartter syndrome.
Hypervitaminosis D.
Idiopathic hypercalciuria.
Hyperoxaluria.
Cortical necrosis.
Tuberculosis.
Idiopathic hypercalciuria.
Rapidly progressive osteoporosis.

NEPHROPATHY, OBSTRUCTIVE[90]

ICD-10CM # Varies with specific diagnosis

POSSIBLE CAUSES OF OBSTRUCTIVE NEPHROPATHY

Renal
Congenital
Polycystic kidney.
Renal cyst.
Peripelvic cyst.
Ureteropelvic junction obstruction.
Neoplastic
Wilms tumor.
Renal cell carcinoma.
Transitional cell carcinoma of the collecting system.
Multiple myeloma.
Inflammatory
Tuberculosis.
Echinococcus infection.
Metabolic
Calculi.
Miscellaneous
Sloughed papillae.
Trauma.
Renal artery aneurysm.
Ureter
Congenital
Stricture.
Ureterocele.
Obstructing megaureter.
Retrocaval ureter.
Prune belly syndrome.
Neoplastic
Primary carcinoma of ureter.
Metastatic carcinoma.
Inflammatory
Tuberculosis.
Amyloidosis.
Schistosomiasis.
Abscess.
Ureteritis cystica.
Endometriosis.
Miscellaneous
Retroperitoneal fibrosis.
Pelvic lipomatosis.
Aortic aneurysm.
Radiation therapy.
Lymphocele.
Trauma.
Urinoma.
Pregnancy.
Radiofrequency ablation.
Bladder and Urethra
Congenital
Posterior urethral valve.
Phimosis.
Hydrocolpos.
Neoplastic
Bladder carcinoma.
Prostate carcinoma.
Carcinoma of urethra.
Carcinoma of penis.
Inflammatory
Prostatitis.
Paraurethral abscess.

Miscellaneous
Benign prostatic hypertrophy.
Neurogenic bladder.
Urethral stricture.

NEUROGENIC BLADDER[66]

ICD-10CM #		
	N31.9	Neuromuscular dysfunction of bladder, unspecified

SUPRATENTORIAL
CVA.
Parkinson disease.
Alzheimer disease.
Cerebral palsy.

SPINAL CORD
Spinal cord injury.
Spinal stenosis.
Central cord syndrome.
ALS.
Multiple sclerosis.
Myelodysplasia.

PERIPHERAL NEUROPATHY
Diabetes.
Alcohol.
Shingles.
Syphilis.

NEUROLOGIC DEFICIT, FOCAL[58]

ICD-10CM #		
	G45.9	Transient cerebral ischemic attack, unspecified
	I67.848	Other cerebrovascular vasospasm and vasoconstriction

TRAUMATIC: INTRACRANIAL, INTRASPINAL
Subdural hematoma.
Intraparenchymal hemorrhage.
Epidural hematoma.
Traumatic hemorrhagic necrosis.

INFECTIOUS
Brain abscess.
Epidural and subdural abscesses.
Meningitis.

NEOPLASTIC
Primary CNS tumors.
Metastatic tumors.
Syringomyelia.
Vascular.
Thrombosis.
Embolism.
Spontaneous hemorrhage: arteriovenous malformation, aneurysm, hypertensive.

METABOLIC
Hypoglycemia.
B_{12} deficiency.
Postseizure.
Hyperosmolar nonketotic.

OTHER
Migraine.
Bell palsy.
Psychogenic.

NEUROLOGIC DEFICIT, MULTIFOCAL[58]

ICD-10CM #		
	I67.89	Other cerebrovascular disease
	G45.9	Transient cerebral ischemic attack, unspecified
	I67.848	Other cerebrovascular vasospasm and vasoconstriction

Acute disseminated encephalomyelitis: postviral or postimmunization.
Infectious encephalomyelitis: poliovirus, enteroviruses, arbovirus, herpes zoster, Epstein-Barr virus.
Granulomatous encephalomyelitis: sarcoid.
Autoimmune: SLE.
Other: familial spinocerebellar degenerations.

NEUROMUSCULAR JUNCTION DYSFUNCTION[3]

ICD-10CM #		
	N31.9	Neuromuscular dysfunction of bladder, unspecified

DISORDERS OF THE NEUROMUSCULAR JUNCTION
Autoimmune
Myasthenia gravis.
Lambert-Eaton myasthenic syndrome.
Congenital
Presynaptic defects in ACh resynthesis, packaging, or release.
Synaptic defect: congenital end plate AChE deficiency.
Postsynaptic defects: slow-channel syndromes.
Postsynaptic defects: decreased response to ACh.
  Fast-channel syndromes.
  AChR deficiency without kinetic abnormality.
Familial limb-girdle myasthenia.
Toxic
Botulism.
Drug-induced disorders.
Organophosphate intoxication.

Ach, Acetylcholine; *AChE,* acetylcholinesterase; *AChR,* acetylcholine receptor.

NEURONOPATHIES, SENSORY (GANGLIONOPATHIES)[7]

ICD-10CM #		
	G60.0	Hereditary motor and sensory neuropathy

Herpes:
  Herpes simplex I and II.
  Varicella zoster (shingles).
Inflammatory sensory polyganglionopathy (ISP).
Paraneoplastic.
Primary biliary cirrhosis.
Sjögren syndrome (keratoconjunctivitis sicca).
Toxin-induced:
  Pyridoxine (vitamin B_6) overdose.
  Metals:
    Platinum (cisplatin).
    Methyl mercury.
Vitamin E deficiency.

NEUROPATHIC BLADDER

ICD-10CM #		
	N31.9	Neuromuscular dysfunction of bladder, unspecified

Diabetes.
Stroke.
Multiple sclerosis.
Parkinson disease.
Dementia.
Encephalopathy.
Brain trauma.
Spinal cord trauma.
Pelvic surgery.
Spina bifida.

NEUROPATHIES WITH FACIAL NERVE INVOLVEMENT

ICD-10CM #		
	G51.8	Other disorders of facial nerve

Sarcoidosis.
HIV.
Lyme disease.
Guillain-Barré.
Others: chronic inflammatory polyneuropathy, Tangier disease, amyloidosis.

NEUROPATHIES, AUTONOMIC[53]

ICD-10CM #		
	G63	Polyneuropathy in diseases classified elsewhere

GUILLAIN-BARRÉ SYNDROME
Non–Guillain-Barré syndrome autoimmunity.
Paraneoplastic (type I antineuronal nuclear antibody).
Lambert-Eaton syndrome.
Antibodies to neuronal nicotinic acetylcholine receptors.
Antibodies to P/Q type calcium channels.
Other autoantibodies.
Systemic lupus erythematosus.

HEREDITARY
Type I autosomal dominant.
Type II autosomal recessive (Morvan disease).
Type III autosomal recessive (Riley-Day).
Type IV autosomal recessive (congenital insensitivity to pain with anhidrosis).
Type V absence of pain.

METABOLIC
Fabry disease.
Diabetes mellitus.
Tangier disease.
Porphyria.

INFECTIOUS
HIV.
Chagas disease.
Botulism.
Leprosy.
Diphtheria.

OTHER
Triple A (Allgrove) syndrome.
Navajo Indian neuropathy.
Multiple endocrine neoplasia type 2b.
TOXINS

NEUROPATHIES, AUTONOMIC, PERIPHERAL, CAUSES[34]

ICD-10CM #		
	G90.09	Other idiopathic peripheral autonomic neuropathy

METABOLIC
Diabetes mellitus.
Alcohol.
Acute intermittent porphyria.
Uremia.

AUTOIMMUNE
Autoimmune autonomic ganglionopathy.
Guillain-Barré syndrome.
Morvan syndrome.
Lambert-Eaton myasthenic syndrome.
Chronic inflammatory demyelinating polyradiculoneuropathy.
Sjögren syndrome.
Systemic lupus erythematosus.
Mixed connective tissue diseases.

PARAPROTEINEMIC
Amyloidosis.

NUTRITIONAL
Cyanocobalamin deficiency.
Thiamine deficiency.
Gluten-sensitive neuropathy.

TOXIC
Heavy metals.
Organic solvents.
Organophosphates.
Vacor.
Acrylamide.

DRUG INDUCED
Cisplatin.
Vincristine.
Amiodarone.
Metronidazole.
Perhexiline.
Paclitaxel.

INFECTIOUS
HIV.
Leprosy.
Chagas disease.
Botulism.
Diphtheria.
Lyme disease.

GENETIC
Hereditary sensory and autonomic neuropathies:
Types I and II.
Type III (familial dysautonomia).
Type IV (congenital insensitivity to pain).
Type V.
Fabry disease.

IDIOPATHIC
Adie syndrome.
Ross syndrome.
Acute cholinergic neuropathy.
Chronic idiopathic anhidrosis.
Amyotrophic lateral sclerosis.

NEUROPATHIES, PAINFUL[93]

ICD-10CM #		
	G58.9	Mononeuropathy, unspecified
	G62.1	Alcoholic polyneuropathy
	G61.89	Other inflammatory polyneuropathies
	G60.0	Hereditary motor and sensory neuropathy
	G60.0	Hereditary motor and sensory neuropathy
	E11.42	Type 2 diabetes mellitus with diabetic polyneuropathy
	E10.42	Type 1 diabetes mellitus with diabetic polyneuropathy

MONONEUROPATHIES
Compressive neuropathy (carpal tunnel, meralgia paresthetica).
Trigeminal neuralgia.
Ischemic neuropathy.
Polyarteritis nodosa.
Diabetic mononeuropathy.
Herpes zoster.
Idiopathic and familial brachial plexopathy.

POLYNEUROPATHIES
DM.
Paraneoplastic sensory neuropathy.
Nutritional neuropathy.
Multiple myeloma.
Amyloid.
Dominantly inherited sensory neuropathy.
Toxic (arsenic, thallium, metronidazole).
AIDS-associated neuropathy.
Tangier disease.
Fabry disease.

NEUROPATHIES, PERIPHERAL, ASYMMETRICAL PROXIMAL/DISTAL[7]

ICD-10CM #		
	G99.0	Autonomic neuropathy in diseases classified elsewhere

BRACHIAL PLEXOPATHY
Open
Direct plexus injury (knife or gunshot wound).
Neurovascular (plexus ischemia).
Iatrogenic (central line insertion).
Closed
Traction injuries:
"Stingers."
Traction neurapraxia.
Partial or complete nerve root avulsion.
Radiation.
Neoplastic.
Idiopathic brachial plexitis.
Thoracic outlet.

LUMBOSACRAL PLEXOPATHIES
Open
Closed
Traction injuries:
Pelvic double vertical shearing fracture.
Posterior hip dislocation.
Retroperitoneal hemorrhage.
Vasospastic (deep buttock injection).
Neoplastic.
Radiation.
Idiopathic lumbosacral plexitis.
Infectious:
Herpesvirus (sacrococcygeal).
Herpes simplex II.
Herpes zoster.
Cytomegalovirus (CMV) polyradiculopathy (HIV).

NEUROPATHIES, TOXIC AND METABOLIC[53]

ICD-10CM #		
	NEC G62.2	Toxic neuropathy

METALS
Arsenic (insecticide, herbicide).
Lead (paint, batteries, pottery).
Mercury (metallic, vapor).
Thallium (rodenticides).
Gold.

OCCUPATIONAL OR INDUSTRIAL CHEMICALS
Acrylamide (grouting, flocculation).
Carbon disulfide (solvent).
Cyanide.
Dichlorophenoxyacetate.
Dimethylaminopropionitrite.
Ethylene oxide (gas sterilization).
Hexacarbons (glue, solvents).
Organophosphates (insecticides, petroleum additive).
Polychlorinated biphenyls.
Tetrachlorbiphenyl.
Trichloroethylene.

DRUGS
Amiodarone.
Chloramphenicol.
Chloroquine.
Cisplatin.
Colchicine.
Dapsone.
Ethambutol.
Ethanol.

Gold.
Hydralazine.
Isoniazid.
Metronidazole.
Nitrofurantoin.
Nitrous oxide.
Nucleosides (antiretroviral agents ddC, ddI, d4T, others).
Penicillamine.
Pentamidine.
Phenytoin.
Pyridoxine (excessive).
Statins.
Stilbamidine.
Suramin.
Taxanes (paclitaxel, docetaxel).
Thalidomide.
Tryptophan (eosinophilia-myalgia syndrome).
Vincristine.

METABOLIC DISORDER

Fabry disease.
Krabbe disease.
Leukodystrophies.
Porphyria.
Tangier disease.
Tyrosinemia.
Uremia.

NEUTROPENIA, DRUG-INDUCED[44]

ICD-10CM # D70.9 Other neutropenia

DRUGS COMMONLY ASSOCIATED WITH NEUTROPENIA

Antibiotics:
- Vancomycin.
- Semisynthetic penicillins.
- Chloramphenicol.
- Sulfa.
- Linezolid.

Antithyroid drugs:
- Methimazole.
- Propylthiouracil.

Cardiovascular:
- Ticlopidine.
- Procainamide.

Antipsychotics:
- Clozapine.
- Olanzapine.
- Chlorpromazine.

Anticonvulsants:
- Phenytoin.
- Carbamazepine
- Valproic acid.

Antiinflammatory agents:
- Indomethacin.
- Sulfasalazine.
- Phenylbutazone.

H2 blockers:
- Cimetidine.
- Ranitidine.

Analgesics:
- Dipyrone.

Antineoplastic:
- Rituximab.

Anthelminthic:
- Levamisole.

NEUTROPENIA WITH DECREASED MARROW RESERVE[45]

ICD-10CM # D70.8 Other neutropenia

PRIMARY

Severe congenital neutropenia.
Shwachman–Diamond syndrome.
Cyclic neutropenia.

SECONDARY

Lymphoproliferative disorder of granular lymphocytes.
Chemotherapy.
Drug induced (nonimmune).
Nutritional.
Viral infection (varicella, EBV, measles, CMV, hepatitis, HIV).

NEUTROPENIA WITH NORMAL MARROW RESERVE[45]

ICD-10CM # D70.9 Neutropenia, unspecified

Chronic benign neutropenia of infancy and childhood.
Ethnic or benign familial neutropenia.
Autoimmune neutropenia.
Alloimmune neutropenia.
Drug-induced neutropenia.
Infection-related neutropenia.
Hypersplenism.

NEUTROPENIA, IN CHILDHOOD[87]

ICD-10CM # D70.8 Other neutropenia
D70.9 Neutropenia unspecified

ACQUIRED

Infection.
Immune mediated.
Hypersplenism.
Vitamin B_{12}, folate, copper deficiency.
Drugs or toxic substances.
Aplastic anemia.
Malignancies or preleukemic disorders.
Ionizing radiation.

CONGENITAL

Cyclic neutropenia.
Severe congenital neutropenia (Kostmann syndrome).
Chronic benign neutropenia of childhood.
Shwachman-Diamond syndrome.
Fanconi anemia.
Metabolic disorders (amino acidopathies, Barth syndrome, glycogen storage disorders).
Osteopetrosis.
Neutropenia with pigmentation abnormalities, e.g., Chédiak-Higashi.

NEUTROPHILIA[45]

ICD-10CM # D72.0 Neutrophilia, hereditary giant
D71 Functional disorders of polymorphonuclear neutrophils

CLASSIFICATION OF NEUTROPHILIA

Primary (No Other Evident Associated Disease)

Hereditary neutrophilia.
Chronic idiopathic neutrophilia.
Chronic myelogenous leukemia (CML) and other myeloproliferative diseases.
Familial myeloproliferative disease.
Congenital anomalies and leukemoid reaction.
Leukocyte adhesion factor deficiency (LAD).
Familial cold urticaria and leukocytosis.

Secondary

Infection.
Stress neutrophilia.
Chronic inflammation.
Drug induced.
Nonhematologic malignancy.
Generalized marrow stimulation as in hemolysis.
Asplenia and hyposplenism.

NIPPLE DISCHARGE[54]

ICD-10CM # Varies with specific diagnosis

Pregnancy.
Hormones (oral contraceptives, estrogen, progesterone).
Blood pressure drugs (methyldopa, verapamil).
Tricyclic antidepressants.
Tranquilizers (antipsychotics).
Antinausea drugs (metoclopramide).
Herbs (nettle, fennel, blessed thistle, anise, fenugreek seed).
Illicit drugs (marijuana, opiates).
Stimulation of the breast (sexual or from exercise).
Thyroid abnormalities.
Chronic emotional stress.
Hypothalamic tumors.
Chest wall conditions.
Herpes zoster.
Trauma.
Burns.
Tumors.
Breast conditions:
- Mammary duct ectasia.
- Chronic cystic mastitis.
- Intraductal cysts.
- Intraductal papillomas.

NIPPLE LESIONS

ICD-10CM # Varies with specific diagnosis

Contact dermatitis.
Trauma.
Paget disease.
Sebaceous hyperplasia.
Neurofibroma.
Accessory nipple.
Papillary adenoma.
Nevoid hyperkeratosis.
Cellulitis.

NODULAR LESIONS, SKIN

ICD-10CM # R22.9 Localized swelling, mass and lump, unspecified

Lipoma.
Cherry angioma.
Angiokeratoma.
Hemangioma.
Classic Kaposi sarcoma.
Nodular melanoma.
Pyogenic granuloma.
Angiosarcoma.
Eccrine poroma.

NODULES, PAINFUL

ICD-10CM # R22.9 Localized swelling, mass and lump, unspecified

Arthropod bite or sting.
Erythema nodosum.
Glomus tumor.
Neuroma.
Leiomyoma.
Angiolipoma.
Dermatofibroma.
Osler node.
Blue rubber bleb nevus.
Vasculitis.
Sweet syndrome.

NYSTAGMUS

ICD-10CM # H55.00 Unspecified nystagmus
H55.89 Other irregular eye movements

Medications (meperidine, barbiturates, phenytoin, phenothiazines, etc.).
Multiple sclerosis.
Congenital.
Neoplasm (cerebellar, brain stem, cerebral).
Labyrinthine or vestibular lesions.
CNS infections.
Optic atrophy.
Other: Arnold–Chiari malformation, syringobulbia, chorioretinitis, meningeal cysts.

NYSTAGMUS, MONOCULAR

ICD-10CM # H55.09 Other forms of nystagmus
H55.00 Unspecified nystagmus

Amblyopia.
Strabismus.
Multiple sclerosis.
Monocular blindness.
Internuclear ophthalmoplegia.
Lid fasciculations.
Brain stem infarct.

ODYNOPHAGIA[86]

ICD-10CM # Varies with specific diagnosis

CAUSES OF ODYNOPHAGIA

Infections
Herpes simplex virus.
Cytomegalovirus.
Candidiasis.
Chemical, Inflammatory
Gastroesophageal reflux.
Drug induced (Slow-K, tetracyclines, quinidine).
Radiation.
Graft-versus-host disease.
Crohn disease.
Dermatologic diseases (pemphigus and pemphigoid).

OPACIFICATION OF HEMIDIAPHRAGM ON X-RAY[36]

ICD-10CM # Varies with specific diagnosis

CAUSES OF OPACIFICATION OF A HEMITHORAX

Pleural effusion.
Consolidation.
Collapse.
Massive tumor.
Fibrothorax.
Combination of above lesions.
Pneumonectomy.
Lung agenesis.

OPHTHALMOPLEGIA[3]

ICD-10CM # H51.9 Unspecified disorder of binocular movement
H49.00 Third [oculomotor] nerve palsy, unspecified eye

BILATERAL

Botulism.
Myasthenia gravis.
Wernicke encephalopathy.
Acute cranial polyneuropathy.
Brain stem stroke.

UNILATERAL

Carotid-posterior (3rd cranial nerve, pupil involved communicating aneurysm).
Diabetic-idiopathic (3rd or 6th cranial nerve, pupil spared).
Myasthenia gravis.
Brain stem stroke.[29]

OPSOCLONUS[29]

ICD-10CM # H55.89 Other irregular eye movements

Multiple sclerosis.
Encephalitis.
CNS lymphoma.
Hydrocephalus.
Pontine hemorrhage.
Thalamic disorder (glioma, hemorrhage).
Hyperosmolar coma.
Carcinoma, paraneoplastic.
Cocaine.
Medications (e.g., phenytoin, haloperidol, amitriptyline, diazepam, vidarabine).

[29] Spontaneous, multivector, chaotic eye movement.

OPTIC ATROPHY[80]

ICD-10CM # H47.20 Unspecified optic atrophy

CAUSES OF OPTIC ATROPHY

Optic Nerve Compression
Pituitary tumor.
Carotid aneurysm.
Glaucoma.
Optic nerve tumor.
Sphenoid meningioma.
Olfactory groove meningioma.
Optic Neuritis Following Long-standing Papilledema Central Retinal Artery Occlusion Toxic/Metabolic
Diabetes.
Methyl alcohol.
Tobacco.
Quinine.
Ethambutol.
Lead and arsenic.
Anemia.
Secondary to Retinal Disease
Senile macular degeneration.
Retinitis pigmentosa.
Severe chorioretinitis.
Secondary to Trauma
Orbital fracture.
Hereditary
Leber optic atrophy.
Hereditary ataxias.
Spinocerebellar degeneration.

OPTIC DISC ELEVATION[12]

ICD-10CM # Varies with specific diagnosis

CAUSES OF OPTIC DISC ELEVATION

Papilloedema.
Accelerated hypertension.
Anterior optic neuropathy.
Ischemic.
Inflammatory.
Infiltrative.
Compressive, including orbital disease.
Pseudopapilloedema.
Disc drusen.
Tilted optic disc.
Peripapillary myelinated nerve fibers.
Crowded disc in hypermetropia.
Mitochondrial optic neuropathies.
Leber hereditary optic neuropathy.
Methanol poisoning.
Intraocular disease.
Central retinal vein occlusion.
Uveitis.
Posterior scleritis.
Hypotony.

ORAL MUCOSA, ERYTHEMATOUS LESIONS[20]

ICD-10CM # K12.2 Cellulitis and abscess of mouth
K13.70 Unspecified lesions of oral mucosa
K13.79 Other lesions of oral mucosa

NODULAR LESIONS, SKIN

ICD-10CM # R22.9 Localized swelling, mass and lump, unspecified

Lipoma.
Cherry angioma.
Angiokeratoma.
Hemangioma.
Classic Kaposi sarcoma.
Nodular melanoma.
Pyogenic granuloma.
Angiosarcoma.
Eccrine poroma.

NODULES, PAINFUL

ICD-10CM # R22.9 Localized swelling, mass and lump, unspecified

Arthropod bite or sting.
Erythema nodosum.
Glomus tumor.
Neuroma.
Leiomyoma.
Angiolipoma.
Dermatofibroma.
Osler node.
Blue rubber bleb nevus.
Vasculitis.
Sweet syndrome.

NYSTAGMUS

ICD-10CM # H55.00 Unspecified nystagmus
H55.89 Other irregular eye movements

Medications (meperidine, barbiturates, phenytoin, phenothiazines, etc.).
Multiple sclerosis.
Congenital.
Neoplasm (cerebellar, brain stem, cerebral).
Labyrinthine or vestibular lesions.
CNS infections.
Optic atrophy.
Other: Arnold–Chiari malformation, syringobulbia, chorioretinitis, meningeal cysts.

NYSTAGMUS, MONOCULAR

ICD-10CM # H55.09 Other forms of nystagmus
H55.00 Unspecified nystagmus

Amblyopia.
Strabismus.
Multiple sclerosis.
Monocular blindness.
Internuclear ophthalmoplegia.
Lid fasciculations.
Brain stem infarct.

ODYNOPHAGIA[86]

ICD-10CM # Varies with specific diagnosis

CAUSES OF ODYNOPHAGIA

Infections
Herpes simplex virus.
Cytomegalovirus.
Candidiasis.
Chemical, Inflammatory
Gastroesophageal reflux.
Drug induced (Slow-K, tetracyclines, quinidine).
Radiation.
Graft-versus-host disease.
Crohn disease.
Dermatologic diseases (pemphigus and pemphigoid).

OPACIFICATION OF HEMIDIAPHRAGM ON X-RAY[36]

ICD-10CM # Varies with specific diagnosis

CAUSES OF OPACIFICATION OF A HEMITHORAX

Pleural effusion.
Consolidation.
Collapse.
Massive tumor.
Fibrothorax.
Combination of above lesions.
Pneumonectomy.
Lung agenesis.

OPHTHALMOPLEGIA[3]

ICD-10CM # H51.9 Unspecified disorder of binocular movement
H49.00 Third [oculomotor] nerve palsy, unspecified eye

BILATERAL

Botulism.
Myasthenia gravis.
Wernicke encephalopathy.
Acute cranial polyneuropathy.
Brain stem stroke.

UNILATERAL

Carotid-posterior (3rd cranial nerve, pupil involved communicating aneurysm).
Diabetic-idiopathic (3rd or 6th cranial nerve, pupil spared).
Myasthenia gravis.
Brain stem stroke.[29]

OPSOCLONUS[29]

ICD-10CM # H55.89 Other irregular eye movements

Multiple sclerosis.
Encephalitis.
CNS lymphoma.
Hydrocephalus.
Pontine hemorrhage.
Thalamic disorder (glioma, hemorrhage).
Hyperosmolar coma.
Carcinoma, paraneoplastic.
Cocaine.
Medications (e.g., phenytoin, haloperidol, amitriptyline, diazepam, vidarabine).

[29] Spontaneous, multivector, chaotic eye movement.

OPTIC ATROPHY[80]

ICD-10CM # H47.20 Unspecified optic atrophy

CAUSES OF OPTIC ATROPHY

Optic Nerve Compression
Pituitary tumor.
Carotid aneurysm.
Glaucoma.
Optic nerve tumor.
Sphenoid meningioma.
Olfactory groove meningioma.
Optic Neuritis Following Long-standing Papilledema Central Retinal Artery Occlusion Toxic/Metabolic
Diabetes.
Methyl alcohol.
Tobacco.
Quinine.
Ethambutol.
Lead and arsenic.
Anemia.
Secondary to Retinal Disease
Senile macular degeneration.
Retinitis pigmentosa.
Severe chorioretinitis.
Secondary to Trauma
Orbital fracture.
Hereditary
Leber optic atrophy.
Hereditary ataxias.
Spinocerebellar degeneration.

OPTIC DISC ELEVATION[12]

ICD-10CM # Varies with specific diagnosis

CAUSES OF OPTIC DISC ELEVATION

Papilloedema.
Accelerated hypertension.
Anterior optic neuropathy.
Ischemic.
Inflammatory.
Infiltrative.
Compressive, including orbital disease.
Pseudopapilloedema.
Disc drusen.
Tilted optic disc.
Peripapillary myelinated nerve fibers.
Crowded disc in hypermetropia.
Mitochondrial optic neuropathies.
Leber hereditary optic neuropathy.
Methanol poisoning.
Intraocular disease.
Central retinal vein occlusion.
Uveitis.
Posterior scleritis.
Hypotony.

ORAL MUCOSA, ERYTHEMATOUS LESIONS[20]

ICD-10CM # K12.2 Cellulitis and abscess of mouth
K13.70 Unspecified lesions of oral mucosa
K13.79 Other lesions of oral mucosa

Allergy.
Erythroplakia.
Candidiasis.
Geographic tongue.
Stomatitis areata migrans.
Plasma cell gingivitis.
Pemphigus vulgaris.

ORAL MUCOSA, PIGMENTED LESIONS[20]

ICD-10CM #		
	K12.2	Cellulitis and abscess of mouth
	K13.70	Unspecified lesions of oral mucosa
	K13.79	Other lesions of oral mucosa
	K13.5	Oral submucous fibrosis

Racial pigmentation.
Oral melanotic macule.
Peutz-Jeghers syndrome.
Neurofibromatosis.
Albright syndrome.
Addison disease.
Chloasma.
Drug reaction: quinacrine, Minocin, chlorpromazine, Myleran.
Amalgam tattoo.
Lead line.
Smoker's melanosis.
Nevi.
Melanoma.

ORAL MUCOSA, PUNCTATE EROSIVE LESIONS[20]

ICD-10CM #		
	K12.2	Cellulitis and abscess of mouth
	K13.70	Unspecified lesions of oral mucosa
	K13.79	Other lesions of oral mucosa

Viral lesion: herpes simplex, coxsackievirus (A, B, A16), herpes zoster.
Aphthous stomatitis.
Sutton disease (giant aphthae).
Behçet syndrome.
Reiter syndrome.
Neutropenia.
Acute necrotizing ulcerative gingivostomatitis (ANUG).
Drug reaction.
Inflammatory bowel disease.
Contact allergy.

ORAL MUCOSA, WHITE LESIONS[20]

ICD-10CM #		
	K12.2	Cellulitis and abscess of mouth
	K13.70	Unspecified lesions of oral mucosa
	K13.79	Other lesions of oral mucosa
	K13.5	Oral submucous fibrosis

Leukoplakia.
White, hairy leukoplakia.
Squamous cell carcinoma.
Lichen planus.
Stomatitis nicotinica.
Benign intraepithelial dyskeratosis.
White spongy nevus.
Leukoedema.
Darier-White disease.
Pachyonychia congenital.
Candidiasis.
Allergy.
SLE.

ORAL ULCERS, ACUTE

ICD-10CM #		
	K13.70	Unspecified lesions of oral mucosa
	K13.79	Other lesions of oral mucosa

Trauma (including thermal trauma).
Aphthous stomatitis.
Syphilis.
Herpes simplex infection.
Herpes zoster.

ORAL VESICLES AND ULCERS[3]

ICD-10CM #		
	K13.70	Unspecified lesions of oral mucosa
	K13.79	Other lesions of oral mucosa

Aphthous stomatitis.
Primary herpes simplex infection.
Vincent stomatitis.
Syphilis.
Coxsackievirus A (herpangina).
Fungi (histoplasmosis).
Behçet syndrome.
SLE.
Reiter syndrome.
Crohn disease.
Erythema multiforme.
Pemphigus.
Pemphigoid.

ORBITAL INFLAMMATION[12]

ICD-10CM #		
	H05.019	Cellulitis of unspecified orbit
	C69.10	Malignant neoplasm of unspecified orbit
	D31.60	Benign neoplasm of unspecified orbit
	H05.029	Osteomyelitis of unspecified orbit
	H05.049	Tendonitis of unspecified orbit
	H05.229	Edema of unspecified orbit
	H05.239	Hemorrhage of unspecified orbit

DIFFERENTIAL DIAGNOSIS OF AN ACUTELY INFLAMED ORBIT

Infection
Bacterial orbital cellulitis.
Fungal orbital infection.
Dacryocystitis.
Infective dacryoadenitis.
Vascular lesions
Acute orbital hemorrhage,
Cavernous sinus thrombosis.
Carotid–cavernous fistula.
Neoplasia
Rapidly progressive retinoblastoma.
Lacrimal gland tumor.
Other neoplasms (e.g., metastatic lesion with inflammation, lymphoma, Waldenström macroglobulinemia).
Rhabdomyosarcoma, leukemia, lymphangioma, or neuroblastoma in children
Endocrine
Thyroid eye disease of rapid onset.
Non-neoplastic inflammation
Idiopathic orbital inflammatory disease.
Tolosa–Hunt syndrome.
Orbital myositis.
Acute allergic conjunctivitis with lid swelling.
Herpes zoster ophthalmicus.
Herpes simplex skin rash.
Sarcoidosis.
Vasculitides: Wegener granulomatosis, polyarteritis nodosa.
Scleritis, including posterior scleritis.
Ruptured dermoid cyst.

ORBITAL LESIONS, CALCIFIED

ICD-10CM #		
	H05.89	Other disorders of orbit

Chronic inflammation.
Phlebolith.
Dermoid cyst.
Mucocele walls.
Tumors (lacrimal gland, fibro-osseous).
Meningioma (optic sheath).
Lymphangioma.
Orbital varix.

ORBITAL LESIONS, CYSTIC

ICD-10CM #		
	H05.9	Unspecified disorder of orbit

Sweat gland cyst.
Dermoid cyst.
Lacrimal gland cyst.
Abscess.
Conjunctival cyst.
Lymphangioma.
Schwannoma.

ORBITAL NEOPLASMS, MALIGNANT[64]

ICD-10CM #		
	C69.10	Malignant neoplasm of unspecified orbit

LESIONS WITH CLINICALLY MALIGNANT BEHAVIOR

Langerhans cell tumors.
Non-Langerhans cell tumors.
Atypical lymphoid hyperplasia.
Meningioma of optic nerve.

[a] Relatively common tumor.

PRIMARY MALIGNANT TUMORS OF ORBIT

Lymphoma.
Lacrimal gland carcinomas.
Rhabdomyosarcoma.
Primitive neuroectodermal tumors.
Malignant peripheral nerve sheath tumor.
Alveolar soft part sarcoma.
Melanoma.
Osteosarcoma.
Fibrosarcoma.
Leiomyosarcoma.
Chondrosarcoma.
Liposarcoma.
Glioma of optic nerve.

SECONDARY MALIGNANT TUMORS OF ORBIT

Eyelid malignancies.
Conjunctival malignancies.
Uveal melanoma.
Retinoblastoma.
Lacrimal drainage system malignancies.
Paranasal sinus and nasal carcinoma.
Brain tumors.

METASTATIC TUMORS OF ORBIT

Distant carcinomas (e.g., breast, lung, gastrointestinal tract).
Neuroblastoma.
Leukemia (granulocytic sarcoma).
Carcinoid tumor.
Metastatic melanoma.

ORGASM DYSFUNCTION[24]

ICD-10CM #		
	F52.31	Female orgasmic disorder
	F52.32	Male orgasmic disorder

Anorgasmia: inadequate stimulation or learning.
Spinal cord lesion or injury.
Multiple sclerosis.
Alcoholic neuropathy.
Amyotrophic lateral sclerosis.
Spinal cord accident.
Spinal cord trauma.
Peripheral nerve damage.
Radical pelvic surgery.
Herniated lumbar disk.
Hypothyroidism.
Addison disease.
Cushing disease.
Acromegaly.
Hypopituitarism.
Pharmacologic agents (e.g., SSRIs, beta-blockers).
Psychogenic.

OROFACIAL PAIN

ICD-10CM #		
	R51	Facial pain

Dental abscess.
Sinusitis.
Otitis media.
Otitis externa.
Wisdom tooth eruption.
Sialoadenitis.
Herpes zoster.
Trigeminal neuralgia.
Parotitis.
Anxiety disorder.
Malingering.

OSTEOLYTIC BENIGN BONE LESIONS, MULTIPLE[71]

ICD-10CM #	
	Varies with specific diagnosis

COMMON MULTIPLE OSTEOLYTIC BENIGN LESIONS

Cystic lesions in joint disease.
Amyloidosis.
Brown tumors in hyperparathyroidism.
Enchondromatosis.
Fibrous dysplasia.
Osteomyelitis (including tuberculosis, hydatid, sarcoid, etc.).
Massive osteolysis (Gorham disease).
Mastocytosis.
Neurofibromatosis.
Langerhans cell histiocytosis (histiocytosis X).

OSTEOMYELITIS, PEDIATRIC PATIENT[19]

ICD-10CM #		
	M86	Osteomyelitis

Fractures.
Thrombophlebitis.
Scurvy.
Septicemia.
Cellulitis.
Septic bursitis.
Myositis.
Pyomyositis.
Rheumatic fever.
Toxic synovitis.
Reactive arthritis.
Complex regional pain syndrome.
Chronic recurrent multifocal osteomyelitis.
Osteoid osteoma.
Langerhans cell histiocytosis.
Leukemia.
Ewing sarcoma.
Malignant primary bone tumors.
Bone infarction (sickle-cell or Gaucher disease).

OSTEOPOROSIS IN CHILDREN[71]

ICD-10CM #		
	M81.8	Other osteoporosis without current pathological fracture

CAUSES OF OSTEOPOROSIS IN CHILDREN

Systemic long-term oral glucocorticoid therapy.
Chronic inflammatory disease (e.g., juvenile inflammatory arthritis).
Hypogonadism—primary or secondary.
Prolonged immobilization.
Osteogenesis imperfecta.
Idiopathic juvenile osteoporosis.

OSTEOPOROSIS, SECONDARY CAUSES

ICD-10CM #		
	M81.0	Age-related osteoporosis without current pathological fracture

Medication induced (e.g., glucocorticoids, anticonvulsants, heparin, LHRH agonists or antagonists).
Hyperparathyroidism.
Hyperthyroidism.
Prolonged immobilization.
Chronic renal failure.
Sickle cell disease.
Multiple myeloma.
Myeloproliferative diseases.
Leukemias and lymphomas.
Acromegaly.
Prolactinoma.
DM.
Total parenteral nutrition.
Malabsorption.
Chronic hypophosphatemia.
Connective tissue disorders (e.g., osteogenesis imperfecta, Marfan syndrome, Ehlers-Danlos).
Hepatobiliary disease.
Postgastrectomy.
Aluminum-containing antacids.
Systemic mastocytosis.
Homocystinuria.[30]

OSTEOSCLEROSIS, DIFFUSE[36]

ICD-10CM #		
	Q77.4	Congenital osteosclerosis

DISORDERS ASSOCIATED WITH DIFFUSE OSTEOSCLEROSIS

Neoplastic Causes[30]
Prostate carcinoma, breast carcinoma, GI adenocarcinoma, carcinoid tumors, transitional cell carcinoma of the bladder, myeloma, lymphoma, leukemia.

Hematologic Causes
Sickle cell disorders, mastocytosis, myelofibrosis, polycythemia vera.

Metabolic Causes
Renal osteodystrophy, primary hyperparathyoidism, familial hypophosphatemic osteomalacia, hypervitaminosis D, fluorosis, hypoparathyroidism, pseudohypoparathyroidism.[31]

Primary Osseous Disorders[31]
Osteoporosis.
Pyknodysostosis.
Paget disease.

OSTEOSCLEROTIC BENIGN BONE LESIONS, MULTIPLE[71]

ICD-10CM #		
	Q78.2	Osteosclerosis

[30] Involvement principally of cancellous bone
[31] Involvement of cancellous and cortical bone

COMMON MULTIPLE OSTEOSCLEROTIC BENIGN LESIONS

Bone infarcts.
Bone islands.
Callus.
Osteomyelitis (chronic, multifocal).
Paget disease.
Fibrous dysplasia.
Enchondromatosis.
Mastocytosis.
Matured benign lesions (e.g., nonossifying fibromas).
Osteomas (Gardner syndrome).
Osteopathia striata.
Osteopoikilosis.

OVARIAN ENLARGEMENT, NONNEOPLASTIC[22]

ICD-10CM #		
	N83.209	Unspecified ovarian cyst, unspecified side
	N83.29	Other ovarian cysts
	N80.1	Endometriosis of ovary
	O00.209	Unspecified ovarian pregnancy without intrauterine pregnancy

NON-NEOPLASTIC CAUSES OF OVARIAN ENLARGEMENT IN THE NONPREGNANT PATIENT

Functional
Hemorrhagic corpus luteum.
Follicle cyst.
Cortical stromal hyperplasia (hyperthecosis).
Polycystic ovarian syndrome (PCOS).
Mesothelial/müllerian.
Endometriotic cyst.
Xanthomatous pseudotumor.
Cystic adhesions/cystic mesothelioma.
Simple cyst.
Vascular
Ovarian torsion/infarction.
Massive ovarian edema.

OVULATORY DYSFUNCTION[49]

ICD-10CM #		
	N97.0	Female infertility associated with anovulation
	N92.3	Ovulation bleeding

HYPERANDROGENIC ANOVULATION

Polycystic ovarian syndrome.
Late-onset congenital adrenal hyperplasias.
Ovarian hyperthecosis.
Androgen-producing ovarian tumors.
Androgen-producing adrenal tumors.
Cushing syndrome.

HYPOESTROGENIC ANOVULATION (HYPOTHALAMIC OR PITUITARY ETIOLOGY)

Hypogonadotropic Hypoestrogenic States
Reversible:
Functional hypothalamic amenorrheas:
Eating disorders (anorexia nervosa, excessive weight loss).
Excessive athletic training.
Neoplastic:
Craniopharyngioma.
Pituitary stalk compression.
Infiltrative diseases:
Histiocytosis-X.
Sarcoidosis.
Hypophysitis.
Pituitary adenomas:
Hyperprolactinemia.
Euprolactinemic galactorrhea.
Endocrinopathies:
Hypothyroidism/hyperthyroidism.
Cushing disease.
Irreversible:
Kallmann syndrome.
Isolated gonadotropin deficiency (hypothalamic or pituitary origin).
Panhypopituitarism/pituitary insufficiency:
Sheehan syndrome, pituitary apoplexy.
Pituitary irradiation or ablation.
Hypergonadotropic Hypoestrogenic States
Physiologic states:
Menopause.
Perimenopause.
Premature ovarian failure.
Immune-related:
Radiation/chemotherapy-induced.
Ovarian dysgenesis.
Turner syndrome.
46XX with mutations of X.
Androgen insensitivity syndrome.

MISCELLANEOUS

Endometriosis.
Luteal phase defect.

PAIN, MIDFOOT

ICD-10CM #		
	M25.579	Pain in unspecified ankle and joints of unspecified foot

MEDIAL ASPECT

Tendonitis of posterior tibialis.
Tendonitis of flexor digitorum longus.
Tendonitis of flexor hallucis longus.
Infection (osteomyelitis, septic arthritis, cellulitis) of foot.
Peripheral vascular insufficiency.
Fracture.
Osteoarthritis.
Gout, pseudogout.
Neuropathy.
Tumor.

LATERAL ASPECT

Peroneus longus tendonitis.
Peroneus brevis tendonitis.
Infection (osteomyelitis, septic arthritis, cellulitis) of foot.
Peripheral vascular insufficiency.
Fracture.
Osteoarthritis.
Gout, pseudogout.
Neuropathy.
Tumor.

PAIN, PLANTAR ASPECT, HEEL

ICD-10CM #		
	M25.579	Pain in unspecified ankle and joints of unspecified foot

Plantar fasciitis.
Tarsal tunnel syndrome.
Neuroma.
Infection (osteomyelitis, septic arthritis, cellulitis) of foot.
Peripheral vascular insufficiency.
Fracture.
Bone cyst.
Osteoarthritis.
Gout, pseudogout.
Neuropathy.
Tumor.
Heel pad atrophy.
Plantar fascia rupture.

PAIN, POSTERIOR HEEL

ICD-10CM #		
	M79.609	Pain in unspecified limb

Achilles tendonitis.
Retrocalcaneal bursitis.
Retroachilles bursitis.
Infection (osteomyelitis, septic arthritis, cellulitis) of foot.
Peripheral vascular insufficiency.
Fracture.
Osteoarthritis.
Gout, pseudogout.
Neuropathy.
Tumor.

PALINDROMIC RHEUMATISM[16]

ICD-10CM #		
	M12.30	Palindromic rheumatism, unspecified site
	M12.319	Palindromic rheumatism, unspecified shoulder
	M12.329	Palindromic rheumatism, unspecified elbow
	M12.339	Palindromic rheumatism, unspecified wrist
	M12.349	Palindromic rheumatism, unspecified hand
	M12.359	Palindromic rheumatism, unspecified hip
	M12.369	Palindromic rheumatism, unspecified knee
	M12.379	Palindromic rheumatism, unspecified ankle and foot
	M12.38	Palindromic rheumatism, vertebrae
	M12.39	Palindromic rheumatism, multiple sites

Palindromic RA.
Essential palindromic rheumatism.
Crystal synovitis (gout, CPPD, pseudogout, calcific periarthritis).
Lyme borreliosis, stages 2 and 3.

COMMON MULTIPLE OSTEOSCLEROTIC BENIGN LESIONS

Bone infarcts.
Bone islands.
Callus.
Osteomyelitis (chronic, multifocal).
Paget disease.
Fibrous dysplasia.
Enchondromatosis.
Mastocytosis.
Matured benign lesions (e.g., nonossifying fibromas).
Osteomas (Gardner syndrome).
Osteopathia striata.
Osteopoikilosis.

OVARIAN ENLARGEMENT, NONNEOPLASTIC[22]

ICD-10CM #		
	N83.209	Unspecified ovarian cyst, unspecified side
	N83.29	Other ovarian cysts
	N80.1	Endometriosis of ovary
	O00.209	Unspecified ovarian pregnancy without intrauterine pregnancy

NON-NEOPLASTIC CAUSES OF OVARIAN ENLARGEMENT IN THE NONPREGNANT PATIENT

Functional
Hemorrhagic corpus luteum.
Follicle cyst.
Cortical stromal hyperplasia (hyperthecosis).
Polycystic ovarian syndrome (PCOS).
Mesothelial/müllerian.
Endometriotic cyst.
Xanthomatous pseudotumor.
Cystic adhesions/cystic mesothelioma.
Simple cyst.
Vascular
Ovarian torsion/infarction.
Massive ovarian edema.

OVULATORY DYSFUNCTION[49]

ICD-10CM #		
	N97.0	Female infertility associated with anovulation
	N92.3	Ovulation bleeding

HYPERANDROGENIC ANOVULATION

Polycystic ovarian syndrome.
Late-onset congenital adrenal hyperplasias.
Ovarian hyperthecosis.
Androgen-producing ovarian tumors.
Androgen-producing adrenal tumors.
Cushing syndrome.

HYPOESTROGENIC ANOVULATION (HYPOTHALAMIC OR PITUITARY ETIOLOGY)

Hypogonadotropic Hypoestrogenic States
Reversible:
Functional hypothalamic amenorrheas:
Eating disorders (anorexia nervosa, excessive weight loss).
Excessive athletic training.
Neoplastic:
Craniopharyngioma.
Pituitary stalk compression.
Infiltrative diseases:
Histiocytosis-X.
Sarcoidosis.
Hypophysitis.
Pituitary adenomas:
Hyperprolactinemia.
Euprolactinemic galactorrhea.
Endocrinopathies:
Hypothyroidism/hyperthyroidism.
Cushing disease.
Irreversible:
Kallmann syndrome.
Isolated gonadotropin deficiency (hypothalamic or pituitary origin).
Panhypopituitarism/pituitary insufficiency:
Sheehan syndrome, pituitary apoplexy.
Pituitary irradiation or ablation.
Hypergonadotropic Hypoestrogenic States
Physiologic states:
Menopause.
Perimenopause.
Premature ovarian failure.
Immune-related:
Radiation/chemotherapy-induced.
Ovarian dysgenesis.
Turner syndrome.
46XX with mutations of X.
Androgen insensitivity syndrome.

MISCELLANEOUS

Endometriosis.
Luteal phase defect.

PAIN, MIDFOOT

ICD-10CM #		
	M25.579	Pain in unspecified ankle and joints of unspecified foot

MEDIAL ASPECT

Tendonitis of posterior tibialis.
Tendonitis of flexor digitorum longus.
Tendonitis of flexor hallucis longus.
Infection (osteomyelitis, septic arthritis, cellulitis) of foot.
Peripheral vascular insufficiency.
Fracture.
Osteoarthritis.
Gout, pseudogout.
Neuropathy.
Tumor.

LATERAL ASPECT

Peroneus longus tendonitis.
Peroneus brevis tendonitis.
Infection (osteomyelitis, septic arthritis, cellulitis) of foot.
Peripheral vascular insufficiency.
Fracture.
Osteoarthritis.
Gout, pseudogout.
Neuropathy.
Tumor.

PAIN, PLANTAR ASPECT, HEEL

ICD-10CM #		
	M25.579	Pain in unspecified ankle and joints of unspecified foot

Plantar fasciitis.
Tarsal tunnel syndrome.
Neuroma.
Infection (osteomyelitis, septic arthritis, cellulitis) of foot.
Peripheral vascular insufficiency.
Fracture.
Bone cyst.
Osteoarthritis.
Gout, pseudogout.
Neuropathy.
Tumor.
Heel pad atrophy.
Plantar fascia rupture.

PAIN, POSTERIOR HEEL

ICD-10CM #		
	M79.609	Pain in unspecified limb

Achilles tendonitis.
Retrocalcaneal bursitis.
Retroachilles bursitis.
Infection (osteomyelitis, septic arthritis, cellulitis) of foot.
Peripheral vascular insufficiency.
Fracture.
Osteoarthritis.
Gout, pseudogout.
Neuropathy.
Tumor.

PALINDROMIC RHEUMATISM[16]

ICD-10CM #		
	M12.30	Palindromic rheumatism, unspecified site
	M12.319	Palindromic rheumatism, unspecified shoulder
	M12.329	Palindromic rheumatism, unspecified elbow
	M12.339	Palindromic rheumatism, unspecified wrist
	M12.349	Palindromic rheumatism, unspecified hand
	M12.359	Palindromic rheumatism, unspecified hip
	M12.369	Palindromic rheumatism, unspecified knee
	M12.379	Palindromic rheumatism, unspecified ankle and foot
	M12.38	Palindromic rheumatism, vertebrae
	M12.39	Palindromic rheumatism, multiple sites

Palindromic RA.
Essential palindromic rheumatism.
Crystal synovitis (gout, CPPD, pseudogout, calcific periarthritis).
Lyme borreliosis, stages 2 and 3.

Sarcoidosis.
Whipple disease.
Acute rheumatic fever.
Reactive arthritis (rare).

PALMOPLANTAR HYPERKERATOSIS

ICD-10CM #		
	L85.1	Acquired keratosis [keratoderma] palmaris et plantaris
	L85.2	Keratosis punctata (palmaris et plantaris)
	L87.0	Keratosis follicularis et parafollicularis in cutem penetrans

Superficial skin infection.
Chronic eczema.
Repeated trauma.
Psoriasis.
Reiter syndrome.
Paraneoplastic acrokeratosis.

PALPITATIONS[76]

ICD-10CM #		
	R00.2	Palpitations

Anxiety.
Electrolyte abnormalities (hypokalemia, hypomagnesemia).
Exercise.
Hyperthyroidism.
Ischemic heart disease.
Ingestion of stimulant drugs (cocaine, amphetamines, caffeine).
Medications (digoxin, beta-blockers, calcium channel antagonists, hydralazines, diuretics, minoxidil).
Hypoglycemia in type 1 DM.
Mitral valve prolapse.
Wolff-Parkinson-White (WPW) syndrome.
Sick sinus syndrome.

PANCREATIC CALCIFICATIONS

ICD-10CM #		
	K86.1	Other chronic pancreatitis
	K86.8	Other specified diseases of pancreas

Chronic pancreatitis.
Hyperparathyroidism.
Metastatic neoplasm.
Pseudocyst.
Hereditary pancreatitis.
Cystoadenoma.
Cystoadenocarcinoma.
Cavernous lymphangioma.
Hemorrhage.
Acute pancreatitis (saponification).

PANCREATIC CYSTIC LESIONS[89]

ICD-10CM #		
	K86.2	Cyst of pancreas
	K86.3	Pseudocyst of pancreas

Pseudocyst.
Serous cystadenoma.
Mucinous cystic neoplasm.
Intraductal papillary mucinous neoplasm.
Solid and papillary epithelial neoplasm.
True epithelial cyst.
Duodenal diverticulum.
Cystic neuroendocrine tumors.
Ductal adenocarcinoma with cystic degeneration.
Cystic metastases.
Cystic degeneration in sarcoma, hemangioma, and paraganglioma.

PANCREATIC SOLID LESIONS[89]

ICD-10CM #		
	C25.9	Malignant neoplasm of pancreas, unspecified
	D13.6	Benign neoplasm of pancreas

Neoplastic solid tumors.
Ductal adenocarcinoma.
Pancreatic neuroendocrine tumor.
Pancreatic lymphoma.
Metastases to the pancreas.
Solid pseudopapillary tumor.
Pancreaticoblastoma.
Acinar cell carcinoma.
Mesenchymal tumors (sarcoma, fibrous histiocytoma, etc.).
Nonneoplastic solid lesions.
Focal chronic pancreatitis.
Autoimmune pancreatitis.
Groove pancreatitis.
Focal sparing of diffuse pancreatic fatty infiltration.
Intrapancreatic accessory spleen.
Developmental pancreas lobulation.
Sarcoidosis of the pancreas.

PANCREATITIS, ACUTE, IN CHILDREN[53]

ICD-10CM #		
	K85	Acute pancreatitis

CAUSES OF ACUTE PANCREATITIS IN CHILDREN

Drugs and Toxins
Acetaminophen overdose.
Alcohol.
L-Asparaginase.
Azathioprine.
Carbamazepine.
Cimetidine.
Corticosteroids.
Enalapril.
Erythromycin.
Estrogen.
Furosemide.
Isoniazid.
Lisinopril.
6-Mercaptopurine.
Methyldopa.
Metronidazole.
Organophosphate poisoning.
Pentamidine.
Retrovirals: DDC, DDI, tenofovir.
Sulfonamides: mesalamine, 5-aminosalicylates, sulfasalazine, trimethoprim/sulfamethoxazole.
Sulindac.
Tetracycline.
Thiazides.
Valproic acid.
Venom (spider, scorpion, Gila monster lizard).
Vincristine.

Genetic
Cationic trypsinogen gene *(PRSS1).*
Chymotrypsin C gene *(CTRC).*
Cystic fibrosis gene *(CFTR).*
Trypsin inhibitor gene *(SPINK1).*

Infectious
Ascariasis.
Coxsackie B virus.
Epstein-Barr virus.
Hepatitis A, B.
Influenza A, B.
Leptospirosis.
Malaria.
Measles.
Mumps.
Mycoplasma.
Reye syndrome: varicella, influenza B.
Rubella.
Rubeola.
Septic shock.

Obstructive
Ampullary disease.
Ascariasis.
Biliary tract malformations.
Choledochal cyst.
Choledochocele.
Cholelithiasis, microlithiasis, and choledocholithiasis (stones or sludge).
Duplication cyst.
Endoscopic retrograde cholangiopancreatography (ERCP) complication.
Pancreas divisum.
Pancreatic ductal abnormalities.
Postoperative.
Sphincter of Oddi dysfunction.
Tumor.

Systemic Disease
Autoimmune pancreatitis.
Brain tumor.
Collagen vascular diseases.
Crohn disease.
Diabetes mellitus.
Head trauma.
Hemochromatosis.
Hemolytic-uremic syndrome.
Hyperlipidemia: type I, IV, V.
Hyperparathyroidism/hypercalcemia.
Kawasaki disease.
Malnutrition.
Organic acidemia.
Peptic ulcer.
Periarteritis nodosa.
Renal failure.
Systemic lupus erythematosus.
Transplantation: bone marrow, heart, liver, kidney, pancreas.

Vasculitis.
Traumatic
Blunt injury.
Burns.
Child abuse.
Hypothermia.
Surgical trauma.
Total body cast.

PANCREATITIS, DRUG-INDUCED[7]

ICD-10CM # K85.3 Drug induced acute pancreatitis

DEFINITE

Acetaminophen.
Azathioprine.
Cimetidine.
Cisplatin.
Corticosteroids.
Didanosine.
Erythromycin.
Estrogens.
Ethyl alcohol.
Furosemide.
L-Asparaginase.
Mercaptopurine.
Metronidazole.
Methyldopa.
Nitrofurantoin.
Octreotide.
Organophosphates.
Pentamidine.
Ranitidine.
Tetracycline.
Salicylates.
Sulfonamides, trimethoprim-sulfamethoxazole, sulfasalazine.
Sulindac.
Valproic acid.

POSSIBLE

Bumetanide.
Carbamazepine.
Chlorthalidone.
Clonidine.
Colchicine.
Cyclosporine.
Cytarabine.
Diazoxide.
Enalapril.
Ergotamine.
Ethacrynic acid.
Indomethacin.
Isoniazid.
Isotretinoin.
Mefenamic acid.
Opiates.
Phenformin.
Piroxicam.
Procainamide.
Rifampin.
Thiazides.

PANCYTOPENIA[45]

ICD-10CM # D61.818 Other pancytopenia

PANCYTOPENIA WITH HYPOCELLULAR BONE MARROW

Acquired aplastic anemia.
Inherited aplastic anemia (Fanconi anemia and others).
Some myelodysplasia syndromes.
Rare aleukemic leukemia (acute myelogenous leukemia).
Some acute lymphoblastic leukemias.
Some lymphomas of bone marrow.

PANCYTOPENIA WITH CELLULAR BONE MARROW

Primary bone marrow diseases.
Myelodysplasia syndromes.
Paroxysmal nocturnal hemoglobinuria.
Myelofibrosis.
Some aleukemic leukemias.
Myelophthisis.
Bone marrow lymphoma.
Hairy cell leukemia.
Secondary to systemic diseases.
Systemic lupus erythematosus, Sjögren syndrome.
Hypersplenism.
Vitamin B_{12}, folate deficiency (familial defect).
Overwhelming infection.
Alcohol.
Brucellosis.
Ehrlichiosis.
Sarcoidosis.
Tuberculosis and atypical mycobacteria.

HYPOCELLULAR BONE MARROW ± CYTOPENIA

Q fever.
Legionnaires disease.
Mycobacteria.
Tuberculosis.[32]
Anorexia nervosa, starvation.
Hypothyroidism.

[32] Pancytopenia in tuberculosis only rarely is associated with a hypocellular bone marrow at biopsy or autopsy. Marrow failure in the setting of tuberculosis is almost always fatal; exceptional patients probably had underlying myelodysplasia or acute leukemia.

PANCYTOPENIA SYNDROME, INHERITED[53]

ICD-10CM # D61.818 Other pancytopenia

Fanconi anemia.
Shwachman-Diamond syndrome.
Dyskeratosis congenita.
Congenital amegakaryocytic thrombocytopenia.
Unclassified inherited bone marrow failure syndromes.
Other genetic syndromes:
- Down syndrome.
- Dubowitz syndrome.
- Seckel syndrome.
- Reticular dysgenesis.
- Schimke immunoosseous dysplasia.
- Familial aplastic anemia (non-Fanconi).
- Cartilage-hair hypoplasia.
- Noonan syndrome.

PAPILLEDEMA

ICD-10CM # H47.10 Unspecified papilledema

CNS infections (viral, bacterial, fungal).
Medications (lithium, cisplatin, corticosteroids, tetracycline, etc.).
Head trauma.
CNS neoplasm (primary or metastatic).
Pseudotumor cerebri.
Cavernous sinus thrombosis.
SLE.
Sarcoidosis.
Subarachnoid hemorrhage.
Carbon dioxide retention.
Arnold–Chiari malformation and other developmental or congenital malformations.
Orbital lesions.
Central retinal vein occlusion.
Hypertensive encephalopathy.
Metabolic abnormalities.

PAPULOSQUAMOUS DISEASES[32]

ICD-10CM # L98.8 Other specified disorders of the skin and subcutaneous tissue

Psoriasis.
Pityriasis rubra pilaris.
Pityriasis rosea.
Lichen planus.
Lichen nitidus.
Secondary syphilis.
Pityriasis lichenoides.
Parapsoriasis.
Mycosis fungoides.
Dermatophytosis.
Tinea versicolor.

PARALYSIS AND MUSCULAR RIGIDITY, DRUG-INDUCED[84]

ICD-10CM # G83 Other paralytic syndromes
R29.818 Other symptoms and signs involving the nervous system

SELECTED AGENTS ASSOCIATED WITH PARALYSIS AND MUSCULAR RIGIDITY

Paralysis
Medications and Industrial Toxins
Aminoglycoside antibiotics.
Beta-blockers.
Chloroquine (with color vision shift).
Cholinesterase inhibitors: neostigmine, pyridostigmine.
d-Penicillamine.
Pesticides: organophosphates, carbamates.
Pyrithioxine.
Trimethadione.
Biologic Toxins
Cobra venom.
Poison hemlock (*Conium maculatum*).
Scorpion fish (Scorpaenidae).

Snake venom, ticks, botulinum toxin.
Star of Bethlehem (*Hippobroma longiflora*).
Sweet pea (*Lathyrus odoratus*).
Tetrodotoxin (puffer fish, blue-ringed octopus, others).

Muscular Rigidity

Black widow spider venom (*Latrodectus mactans*).
Strychnine (*Strychnos nux vomica,* "slang nut").
Tetanus toxin.

PARALYTIC ILEUS[37]

ICD-10CM # K56 Paralytic ileus and intestinal obstruction

CAUSES OF A PARALYTIC ILEUS

Peritonitis.
Surgery.
Trauma:
- *Spine.*
- *Ribs.*
- *Hip.*
- *Retroperitoneum.*

Inflammation:
- *Appendicitis.*
- *Pancreatitis.*
- *Cholecystitis.*
- *Salpingitis.*

Congestive heart failure.
Pneumonia.
Renal colic.
Renal failure.
Leaking abdominal aortic aneurysm.
Low serum potassium.
Drugs (e.g. morphine).
Spinal lesions.
General debility or infection.
Vascular occlusion.

PARANEOPLASTIC NEUROLOGIC SYNDROMES

ICD-10CM # G13.0 Paraneoplastic neuromyopathy and neuropathy

Lambert-Eaton myasthenic syndrome.
Myasthenia gravis.
Guillain-Barré syndrome.
Amyotrophic lateral sclerosis.
Dermatomyositis.
Carcinoid myopathy.
Cerebellar degeneration.
Encephalomyelitis.
Optic neuritis, uveitis, retinopathy.
Stiff-man syndrome.
Autonomic neuropathy.
Brachial neuritis.
Sensory neuropathy.
Progressive multifocal leukoencephalopathy.

PARANEOPLASTIC SYNDROMES, ENDOCRINE[82]

ICD-10CM # G13.0 Paraneoplastic neuromyopathy and neuropathy

Hypercalcemia.
Syndrome of inappropriate secretion of antidiuretic hormone.
Hypoglycemia.
Zollinger-Ellison syndrome.
Ectopic secretion of human chorionic gonadotropin.
Cushing syndrome.

PARANEOPLASTIC SYNDROMES, NONENDOCRINE[82]

ICD-10CM # G13.0 Paraneoplastic neuromyopathy and neuropathy

CUTANEOUS

Dermatomyositis.
Acanthosis nigricans.
Sweet syndrome.
Erythema gyratum repens.
Systemic nodular panniculitis (Weber-Christian disease).

RENAL

Nephrotic syndrome.
Nephrogenic diabetes insipidus.

NEUROLOGIC

Subacute cerebellar degeneration.
Progressive multifocal leukoencephalopathy.
Subacute motor neuropathy.
Sensory neuropathy.
Ascending acute polyneuropathy (Guillain-Barré syndrome).
Myasthenic syndrome (Eaton-Lambert syndrome).

HEMATOLOGIC

Microangiopathic hemolytic anemia.
Migratory thrombophlebitis (Trousseau syndrome).
Anemia of chronic disease.

RHEUMATOLOGIC

Polymyalgia rheumatica.
Hypertrophic pulmonary osteoarthropathy.

PARAPARESIS, ACUTE OR SUBACUTE[80]

ICD-10CM # G82.2 Paraparesis

CAUSES OF ACUTE OR SUBACUTE PARAPARESIS

Trauma to a Previously Normal Spine

Vertebral Disease

Metastatic carcinoma.
Cervical spondylosis.
Dorsal disk prolapse.
Paget disease.
Rheumatoid arthritis.
Pott disease of spine.

Tumors

Extradural or intradural carcinoma, lymphoma, myeloma, leukemia.
Dorsal meningioma.
Neurofibroma.

Hematologic Disease

Any cause of thrombocytopenia.
Other clotting disorders.
Leukemia.
Anticoagulant treatment.
Epidural or intramedullary hemorrhage.

Infection

Epidural abscess.
TB abscess.
Syphilitic myelitis.
HIV infection.
Vascular myelopathy.

Vascular

Anterior spinal artery occlusion.
Infarction secondary to hypotension.
Embolic infarction.
Infarction secondary to aortic dissection.
Arteriovenous malformation: infarction or hemorrhage.
Primary intramedullary hemorrhage.
Vasculitis—polyarteritis nodosa (PAN).

Inflammatory

Myelitis of unknown cause.
Multiple sclerosis.
Systemic lupus erythematosus.
Sarcoidosis.

Metabolic

Subacute degeneration of the cord.

PARAPARESIS, CHRONIC PROGRESSIVE[80]

ICD-10CM # G82.2 Paraparesis

CAUSES OF CHRONIC PROGRESSIVE PARAPARESIS

Vertebral Disease

Cervical spondylosis.
Dorsal disk prolapse.
Rheumatoid arthritis.
Pott disease of spine.
Ankylosing spondylitis.

Tumors

Meningioma.
Neurofibroma.
Glioma.
Ependymoma.
Chordoma.
Lipoma.

Syringomyelia

With Arnold–Chiari malformation.
With tumor.
Posttraumatic.

Infection

Tropical spastic paraparesis (HTLV-1 infection).
Syphilitic myelitis.

Vascular

Arteriovenous malformation.

Inflammatory

Multiple sclerosis.
Sarcoidosis.
Radiation myelopathy.
Arachnoiditis.

Metabolic

Subacute combined degeneration of the cord.
Paget disease.

Degenerative

Motor neuron disease.

Hereditary

Hereditary spastic paraplegia.

PARAPARESIS, PAINLESS[51]

ICD-10CM # G82 Paraplegia (paraparesis) and quadriplegia (quadriparesis)

FREQUENTLY OCCURRING CAUSES OF PAINLESS PARAPARESIS

Inflammatory CNS diseases:
- Multiple sclerosis (MS).
- Neuromyelitis optica (NMO).

Genetic disorders:
- Spinal cerebellar ataxias (SCAs).
- Hereditary spastic paraparesis (HSP).

Infectious illnesses:
- Human T-lymphotropic virus type 1 (HTLV-1) myelopathy.

Compressive lesions*:
- Cervical spondylosis.
- Spinal meningiomas.
- Metastatic tumors.

Neurodegenerative illnesses:
- ALS.

Nutritional deficiencies:
- Copper deficiency.
- Vitamin B_{12} deficiency (combined system disease).

*May be associated with spine pain.

PARAPLEGIA

ICD-10CM # G82.20 Paraplegia, unspecified
G80.1 Spastic diplegic cerebral palsy
I69.969 Other paralytic syndrome following unspecified cerebrovascular disease affecting unspecified side

Trauma: penetrating wounds to motor cortex, fracture-dislocation of vertebral column with compression of spinal cord or cauda equina, prolapsed disk, electrical injuries.
Neoplasm: parasagittal region, vertebrae, meninges, spinal cord, cauda equina, Hodgkin disease, NHL, leukemic deposits, pelvic neoplasms.
Multiple sclerosis and other demyelinating disorders.
Mechanical compression of spinal cord, cauda equina, or lumbosacral plexus: Paget disease, kyphoscoliosis, herniation of intervertebral disk, spondylosis, ankylosing spondylitis, RA, aortic aneurysm.
Infections: spinal abscess, syphilis, TB, poliomyelitis, leprosy.
Thrombosis of superior sagittal sinus.
Polyneuritis: Guillain-Barré syndrome, diabetes, alcohol, beriberi, heavy metals.
Heredofamilial muscular dystrophies.
ALS.
Congenital and familial conditions: syringomyelia, myelomeningocele, myelodysplasia.
Hysteria.

PARASELLAR MASSES[62]

ICD-10CM # Varies with specific diagnosis

GENETIC

Transcription factor mutations (e.g., PROP1[33]).

CYSTS

Rathke.
Arachnoid.
Epidermoid.
Dermoid.

TUMORS

Hormone-secreting or nonfunctional pituitary adenoma.
Granular cell tumor.
Craniopharyngioma (cystic components).
Chordoma.
Meningioma.
Sarcoma.
Glioma.
Schwannoma.
Germ cell tumor.
Vascular tumor.
Solid or hematological metastasis.

MALFORMATION AND HAMARTOMAS

Ectopic pituitary, neurohypophyseal, or salivary tissue.
Hypothalamic hamartoma.
Gangliocytoma.

MISCELLANEOUS LESIONS

Aneurysms.
Hypophysitis.
Infections.
Sarcoidosis.
Giant cell granuloma.
Histiocytosis X.

[33] *PROP1,* Prophet of Pit1 (paired-like homeodomain transcription factor).

PARESTHESIAS

ICD-10CM # R20.2 Paresthesia of skin
G54.8 Other nerve root and plexus disorders

Multiple sclerosis.
Nutritional deficiencies (thiamin, vitamin B_{12}, folic acid).
Compression of spinal cord or peripheral nerves.
Medications (e.g., INH, lithium, nitrofurantoin, gold, cisplatin, hydralazine, amitriptyline, sulfonamides, amiodarone, metronidazole, dapsone, disulfiram, chloramphenicol).
Toxic chemicals (e.g., lead, arsenic, cyanide, mercury, organophosphates).
DM.
Myxedema.
Alcohol.
Sarcoidosis.
Neoplasms.
Infections (HIV, Lyme disease, herpes zoster, leprosy, diphtheria).
Charcot-Marie-Tooth syndrome and other hereditary neuropathies.
Guillain-Barré neuropathy.

PARKINSONISM[84]

ICD-10CM # G20 Parkinson disease
G21 Secondary parkinsonism
G21.9 Secondary parkinsonism, unspecified
G21.19 Other drug-induced Secondary parkinsonism
G21.4 Vascular parkinsonism
G21.2 Secondary parkinsonism due to other external agents

CAUSES OF PARKINSONISM

Static Injury/Structural Disorders
Basal ganglia infarcts.
Brain tumor.
Hydrocephalus.

Hereditary/Degenerative Disorders
Juvenile Parkinson disease.
Spinocerebellar ataxia.
Huntington disease (Westphal variant).
Pallidal-pyramidal disorder.
Neurodegeneration with brain iron accumulation (NBIA).
Pantothenate kinase-associated neurodegeneration (PKAN).
Rett syndrome.
Pelizaeus-Merzbacher disease.
Machado-Joseph disease (spinocerebellar ataxia type 3).
Neuronal ceroid lipofuscinoses.
Neuronal intranuclear inclusion body disease.

Metabolic Disorders
Dopa-responsive dystonia.
Tyrosine hydroxylase deficiency and other abnormalities of bioamine metabolism.
Abnormalities of folate metabolism.
Wilson disease.
Basal ganglia calcification (Fahr syndrome, hypoparathyroidism).

Infectious/Para-Infectious Disorders
Encephalitis lethargica (Von Economo disease).
Autoimmune encephalitides, including anti-NMDA receptor associated encephalitis.
Viral encephalitis.
Acute demyelinating encephalomyelitis.

Drugs/Toxins
1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) poisoning.
Rotenone.
Tetrabenazine.
Reserpine.
Methyldopa.
Sedatives.
Neuroleptics.
Antiemetics.
Calcium channel blockers.
Isoniazid.
Serotonin reuptake inhibitors (sertraline, fluoxetine).
Meperidine.

Disorders That Mimic Parkinsonism
Catatonia.

Spasticity.
Hypothyroidism.
Depression (with psychomotor retardation).

PARKINSONISM AND OTHER ACUTE EXTRAPYRAMIDAL REACTIONS, DRUG-INDUCED[84]

ICD-10CM #		
	G21.19	Other drug-induced secondary parkinsonism

SELECTED AGENTS ASSOCIATED WITH PARKINSONISM AND OTHER ACUTE EXTRAPYRAMIDAL REACTIONS

Medications
Amiodarone.
Anticholinergic agents: benztropine.
Antidepressants (including selective serotonin reuptake inhibitors).
Antiepileptic drugs.
Antifungal agents.
Antihistamines.
Antipsychotics and related drugs (including "novel" agents).
Bethanechol.
Bupropion (acute).
Buspirone.
Captopril (acute).
Clonazepam.
Diazoxide.
Digoxin (chorea).
Estrogen (chorea).
Heroin.
Ketamine.
L-dopa.
Lithium (chorea).
l-Methyl-4-phenyl-1,2,3,6,-tetrahydropyridine (MPTP).
Metronidazole (oculogyric crisis).
Ofloxacin (Tourette-like syndrome).
Opiates/opioids.
Reserpine.
Stimulants.
Sulfasalazine (chorea).
Vinblastine.
Industrial Toxins
Carbon monoxide.
Metals: manganese, thallium, aluminum.
Methanol.
Trichloroethylene.
Biologic Toxins
Arthrinium mycotoxin.

PARKINSONISM-PLUS SYNDROMES

ICD-10CM #		
	G21.8	Other secondary parkinsonism

Parkinson disease.
Shy-Drager syndrome.
Corticobasal degeneration.
Olivo-ponto-cerebellar atrophy.
Dementia with Lewy bodies.
Progressive supranuclear palsy.
Striatonigral degeneration.

PAROTID SWELLING[8]

ICD-10CM #		
	K11.20	Sialoadenitis, unspecified
	B26.9	Mumps without complication
	K11.8	Other diseases of salivary glands
	K11.5	Sialolithiasis
	K11.3	Abscess of salivary gland

INFECTIOUS

Mumps.
Parainfluenza.
Influenza.
Cytomegalovirus infection.
Coxsackievirus infection.
Lymphocytic choriomeningitis.
Echovirus infection.
Suppuration (bacterial).
Actinomyces infection.
Mycobacterial infection.
Cat-scratch disease.

NONINFECTIOUS

Drug hypersensitivity (thiouracil, phenothiazines, thiocyanate, iodides, copper, isoprenaline, lead, mercury, phenylbutazone).
Sarcoidosis.
Tumors, mixed.
Hemangioma, lymphangioma.
Sialectasis.
Sjögren syndrome.
Mikulicz syndrome (scleroderma, mixed connective tissue disease, SLE).
Recurrent idiopathic parotitis.
Pneumoparotitis.
Trauma.
Sialolithiasis.
Foreign body.
Cystic fibrosis.
Malnutrition (marasmus, alcohol cirrhosis).
Dehydration.
DM.
Waldenström macroglobulinemia.
Reiter syndrome (reactive arthritis).
Amyloidosis.

NONPAROTID SWELLING

Hypertrophy of masseter muscle.
Lymphadenopathy.
Rheumatoid mandibular joint swelling.
Tumors of jaw.
Infantile cortical hyperostosis.

PELVIC AVULSION FRACTURES[71]

ICD-10CM #		
	M84.350A	Stress fracture pelvis, initial encounter
	M84.454A	Pathological fracture pelvis, initial encounter

ACUTE AVULSION FRACTURE

Nontraumatic avulsion fracture	Bone metastasis, prior graft harvesting.
Soft tissue injury	Tendon tear, muscle strain.
Aggressive-looking appearance	Osteomyelitis, tumor.
Incidental normal variant	Accessory bone.

CHRONIC AVULSION FRACTURE

Apophyseal avulsion injury	Apophysitis, traction periostitis.
Soft tissue injury	Bursitis, degenerative tendinopathy, calcific tendinitis.

PELVIC MASS

ICD-10CM #		
	R19.09	Other intraabdominal and pelvic swelling, mass and lump

Hemorrhagic ovarian cyst.
Simple ovarian cyst (follicle or corpus luteum).
Ovarian carcinoma, carcinoma of fallopian tube, colorectal carcinoma, metastatic carcinoma, prostate carcinoma, bladder carcinoma, lymphoma, Hodgkin disease.
Cystadenoma, teratoma, endometrioma.
Leiomyoma.
Leiomyosarcoma.
Diverticulitis, diverticular abscess.
Appendiceal abscess, tuboovarian abscess.
Ectopic pregnancy, intrauterine pregnancy.
Paraovarian cyst.
Hydrosalpinx.

PELVIC PAIN, CAUSES IN WOMEN[7]

ICD-10CM #		
	N94	Pain and other conditions associated with female genital organs and menstrual cycle
	G10.2	Pelvic and perineal pain
	G89.4	Chronic pain syndrome

POTENTIAL CAUSES OF PELVIC PAIN IN WOMEN

Reproductive Tract
Ovarian torsion.
Ovarian cyst.
Salpingitis/tubo-ovarian abscess.
Septic pelvic thrombophlebitis.
Endometritis.
Endometriosis.
Uterine perforation.
Uterine fibroids.
Dysmenorrhea.
Pregnancy-related
First Trimester
Ectopic pregnancy.
Threatened abortion.
Nonviable pregnancy.
Ovarian hyperstimulation syndrome.
Second and Third Trimesters
Placenta previa.

Placental abruption.
Round ligament pain.
Intestinal Tract
Appendicitis.
Diverticulitis.
Ischemic bowel.
Perforated viscus.
Bowel obstruction.
Incarcerated/strangulated hernia.
Inflammatory bowel disease.
Gastroenteritis.
Urinary Tract
Pyelonephritis.
Cystitis.
Ureteral stone.

PELVIC PAIN, CHRONIC[17]

ICD-10CM #		
	N94.89	Other specified conditions associated with female genital organs and menstrual cycle
	R10.2	Pelvic and perineal pain
	R10.10	Upper abdominal pain, unspecified
	R10.2	Pelvic and perineal pain
	R10.30	Lower abdominal pain, unspecified

GYNECOLOGIC DISORDERS

Primary dysmenorrhea.
Endometriosis.
Adenomyosis.
Adhesions.
Fibroids.
Retained ovary syndrome after hysterectomy.
Previous tubal ligation.
Chronic pelvic infection.

MUSCULOSKELETAL DISORDERS

Myofascial pain syndrome.

GASTROINTESTINAL DISORDERS

Irritable bowel syndrome.
Inflammatory bowel disease.

URINARY TRACT DISORDERS

Interstitial cystitis.
Nonbacterial urethritis.

PELVIC PAIN, GENITAL ORIGIN[58]

ICD-10CM #		
	N94.89	Other specified conditions associated with female genital organs and menstrual cycle
	R10.2	Pelvic and perineal pain
	R10.10	Upper abdominal pain, unspecified
	R10.2	Pelvic and perineal pain
	R10.30	Lower abdominal pain, unspecified

PERITONEAL IRRITATION

Ruptured ectopic pregnancy.
Ovarian cyst rupture.
Ruptured tuboovarian abscess.
Uterine perforation.

TORSION

Ovarian cyst or tumor.
Pedunculated fibroid.

INTRATUMOR HEMORRHAGE OR INFARCTION

Ovarian cyst.
Solid ovarian tumor.
Uterine leiomyoma.

INFECTION

Endometritis.
Pelvic inflammatory disease.
Trichomonas cervicitis or vaginitis.
Tuboovarian abscess.

PREGNANCY-RELATED

First Trimester
Ectopic pregnancy.
Abortion.
Corpus luteum hematoma.
Late Pregnancy
Placental problems.
Preeclampsia.
Premature labor.

MISCELLANEOUS

Endometriosis.
Foreign objects.
Pelvic adhesions.
Pelvic neoplasm.
Primary dysmenorrhea.

PELVIC PAIN, NON-PREGNANT FEMALE[1]

ICD-10CM #		
	N94.89	Other specified conditions associated with female genital organs and menstrual cycle
	R10.2	Pelvic and perineal pain
	R10.10	Upper abdominal pain, unspecified
	R10.30	Lower abdominal pain, unspecified

DIFFERENTIAL DIAGNOSIS OF PELVIC PAIN IN NONPREGNANT FEMALES

Gynecologic Diagnoses
Infectious:
- Vaginitis.
- Cervicitis.
- Endometritis.
- Tuboovarian abscess.
- Pelvic inflammatory disease.

Ovarian:
- Ovarian torsion.
- Ruptured ovarian cyst.
- Ovarian tumor.
- Degenerating ovarian tumor.
- Mittelschmerz.

Cervical:
- Cervical polyps.
- Cervical stenosis.
- Cervical cancer.

Uterine:
- Uterine fibroids.
- Degenerating uterine fibroids.
- Adenomyosis.
- Endometrial carcinoma.

Extrauterine:
- Endometriosis.
- Adhesions.
- Residual accessory ovary.

Nongynecologic Diagnoses
GI:
- Acute appendicitis.
- Mesenteric lymphadenitis.
- Diverticulitis.
- Inflammatory bowel disease.
- Irritable bowel syndrome.
- Bowel obstruction.
- Intraabdominal abscess.
- Colorectal carcinoma.

Urinary:
- Cystitis.
- Renal colic.
- Bladder cancer.

Musculoskeletal:
- Abdominal wall pain.
- Lumbar back pain.
- Fibromyalgia.
- Muscular strain.
- Piriformis syndrome.

Neurologic:
- Lumbar radiculopathy.
- Shingles.
- Spondylosis.

Psychologic:
- Personality disorders.
- Major depressive disorder.

PENILE RASH

ICD-10CM #		
	R21	Rash and other nonspecific skin eruption

Herpes simplex 2.
Balanitis (*Candida*).
Condyloma acuminatum.
Molluscum contagiosum.
Scabies.
Pediculosis pubis.
Pearly penile papules.
Lichen nitidus.
Fox-Fordyce disease (follicular papules).
Trauma.

PERIANAL PAIN[86]

ICD-10CM #		
	K62.89	Other specified diseases of anus and rectum

Fissure-in-ano.
Anal sepsis:
- Anal abscess.
- Anal fistula.

Hemorrhoids:
- Internal hemorrhoids.
- External hemorrhoids.

Pruritus ani.
Proctalgia fugax.

Chronic perianal pain syndromes:
Coccygodynia.
Descending perineum syndrome.
Levator ani syndrome.
Idiopathic perineal pain.

PERICARDIAL EFFUSION

ICD-10CM #		
	I30.9	Acute pericarditis, unspecified
	I31.3	Pericardial effusion

Pericarditis.
Uremia.
Myxedema.
Neoplasm (leukemia, lymphoma, metastatic).
Hemorrhage (trauma, leakage of thoracic aneurysm).
SLE, rheumatoid disease.
Myocardial infarction.

PERIPHERAL ARTERIAL DISEASE, NONATHEROSCLEROTIC CAUSES[46]

ICD-10CM #		
	I73.9	Peripheral vascular disease, unspecified
	I73.8	Other specified peripheral vascular diseases
	I79.8	Other disorders of arteries, arterioles, and capillaries in diseases classified elsewhere

NONATHEROSCLEROTIC CAUSES OF PERIPHERAL ARTERY DISEASE

Thromboembolism.
Atheroembolism.
Vasculitides:
Large vessel vasculitides, such as giant cell arteritis and Takayasu arteritis.
Small vessel vasculitides, such as thromboangiitis obliterans (Buerger disease).
Trauma.
Popliteal artery entrapment.
Cystic adventitial disease.
Fibromuscular dysplasia.
Iliac artery endofibrosis.

PERIODIC PARALYSIS, HYPERKALEMIC

ICD-10CM #		
	G83.9	Paralytic syndrome, unspecified

Chronic renal failure.
Renal insufficiency with excessive potassium supplementation.
Potassium-sparing diuretics.
Endocrinopathies (hypoaldosteronism, adrenal insufficiency).

PERIODIC PARALYSIS, HYPOKALEMIC

ICD-10CM #		
	G83.9	Paralytic syndrome, unspecified

Chronic diarrhea (laxative abuse, sprue, villous adenoma).
Potassium-depleting diuretics.
Medications (amphotericin B, corticosteroids).
Chronic licorice ingestion.
Thyrotoxicosis.
Renal tubular acidosis.
Conn syndrome.
Barter syndrome.
Barium intoxication.

PERITONEAL CARCINOMATOSIS[32]

ICD-10CM #		
	C78.6	Secondary malignant neoplasm of retroperitoneum and peritoneum

PRIMARY DISORDERS OF THE PERITONEUM: MESOTHELIOMA

Metastatic spread from:
Stomach.
Colon.
Pancreas.
Carcinoid.
Other Intraabdominal Organs
Ovary.
Pseudomyxoma peritonei.
Extraabdominal Primary Tumors
Breast.
Lung.
Hematologic Malignancy
Lymphoma.

PERITONEAL EFFUSION[40]

ICD-10CM #		
	R18	Ascites
	R85.9	Unspecified abnormal finding in specimens from digestive organs and abdominal cavity
	R88.8	Abnormal findings in other body fluids and substances

TRANSUDATES

Increased hydrostatic pressure or decreased plasma oncotic pressure.
Congestive heart failure.
Hepatic cirrhosis.
Hypoproteinemia.

EXUDATES

Increased capillary permeability or decreased lymphatic resorption.
Infections (TB, spontaneous bacterial peritonitis, secondary bacterial peritonitis).
Neoplasms (hepatoma, metastatic carcinoma, lymphoma, mesothelioma).
Trauma.
Pancreatitis.
Bile peritonitis (e.g., ruptured gallbladder).

CHYLOUS EFFUSION

Damage or obstruction to thoracic duct.
Trauma.
Lymphoma.
Carcinoma.
Tuberculosis.
Parasitic infection.

PERIUMBILICAL SWELLING

ICD-10CM #		
	R19.00	Intraabdominal and pelvic swelling, mass and lump, unspecified site

Umbilical hernia.
Lipoma.
Epigastric hernia.
Umbilical granuloma.
Omphalocele.
Gastroschisis.
Caput medusae.

PHARYNGEAL OBSTRUCTION, CAUSES[61]

ICD-10CM #	
	Varies with specific diagnosis

CAUSES OF PHARYNGEAL OBSTRUCTION

Malignant or benign tumors (e.g., papillomas, polyps).
Infection (e.g., croup, epiglottitis, tonsillar abscess).
Edema or hypertrophy (e.g., angioneurotic edema, anaphylactic reactions, postradiation therapy, obstructive sleep apnea).
Trauma (e.g., cricoid fracture, cervical subluxation, precervical hematoma).
Burn injury.
Extrinsic compression (e.g., goiter or pregnancy-related thyroid enlargement).
Foreign body.
Congenital web (infants).
Sarcoidosis and other granulomatous diseases.
Amyloid.

PHEOCHROMOCYTOMA-TYPE SPELLS[62]

ICD-10CM #		
	I15.2	Hypertension due to pheochromocytoma

DIFFERENTIAL DIAGNOSIS OF PHEOCHROMOCYTOMA-TYPE SPELLS

Endocrine Causes
Carbohydrate intolerance.
Hyperadrenergic spells.
Hypoglycemia.
Pancreatic tumors (e.g., insulinoma).
Pheochromocytoma.
Primary hypogonadism (menopausal syndrome).
Thyrotoxicosis.
Cardiovascular Causes
Angina.
Cardiovascular deconditioning.
Labile essential hypertension.
Orthostatic hypotension.
Paroxysmal cardiac arrhythmia.
Pulmonary edema.
Renovascular disease.
Syncope (e.g., vasovagal reaction).
Psychologic Causes
Factitious (e.g., drugs, Valsalva).
Hyperventilation.
Severe anxiety and panic disorders.
Somatization disorder.

Pharmacologic Causes
Chlorpropamide-alcohol flush.
Combination of a monoamine oxidase inhibitor and a decongestant.
Illegal drug ingestion (cocaine, phencyclidine, lysergic acid diethylamide).
Sympathomimetic drug ingestion.
Vancomycin ("red man syndrome").
Withdrawal of adrenergic-inhibitor.
Neurologic Causes
Autonomic neuropathy.
Cerebrovascular insufficiency.
Diencephalic epilepsy (autonomic seizures).
Migraine headache.
Postural orthostatic tachycardia syndrome.
Stroke.
Other Causes
Carcinoid syndrome:
Mast cell disease.
Recurrent idiopathic anaphylaxis.
Unexplained flushing spells.

PHOTODERMATOSES[32]

ICD-10CM #		
	L56.0	Drug phototoxic response
	L56.1	Drug photoallergic response
	L56.2	Photocontact dermatitis [berloque dermatitis]

Polymorphous light eruption.
Chronic actinic dermatitis.
Solar urticaria.
Phototoxicity and photoallergy.
Porphyrias.

PHOTOSENSITIVITY

ICD-10CM #		
	L56.0	Drug phototoxic response
	L56.1	Drug photoallergic response
	L56.2	Photocontact dermatitis [berloque dermatitis]

Solar urticaria.
Photoallergic reaction.
Phototoxic reaction.
Polymorphous light eruption.
Porphyria cutanea tarda.
SLE.
Drug induced (e.g., tetracyclines).

PIGMENTURIA[7]

ICD-10CM #		
	R82	Other abnormal findings in urine

HEMOGLOBINURIA

Hemolysis.

HEMATURIA

Renal causes.
Trauma.

ACUTE INTERMITTENT PORPHYRIA

Bilirubinuria
Food
Beets.
Drugs
Vitamin B_{12}.
Rifampin.
Phenytoin.
Laxatives.

PITUITARY REGION TUMORS[36]

ICD-10CM #	Varies with specific diagnosis

PRIMARY TUMORS IN THE SELLAR AND PARASELLAR REGION

Pituitary macroadenoma.
Meningioma.
Schwannoma (e.g., of fifth nerve).
Chordoma.
Chondrosarcoma.
Craniopharyngioma.
Rathke cleft cyst.
Dermoid.
Epidermoid.
Tuber cinereum hamartoma.
Optic glioma.
Germ cell tumors.

PLATELET DYSFUNCTION, DRUG-INDUCED[46]

ICD-10CM #	D69.1	Qualitative platelet defects

ANTI-PLATELET DRUGS

COX inhibitors: aspirin.
ADP receptor antagonists:
Thienopyridines: clopidogrel, ticlopidine, prasugrel.
Nonthienopyridines: ticagrelor, cangrelor.
$\alpha_{IIb}\beta_3$ inhibitors: abciximab, eptifibatide, tirofiban.
PDE inhibitors:
Nonselective PDE inhibitors: pentoxifylline, caffeine, theophylline.
PDE3 inhibitors: cilostazol, milrinone, anagrelide.
PDE5 inhibitors: dipyridamole, sildenafil.
Adenyl cyclase stimulators: epoprostenol, iloprost, beraprost.
Drugs that adversely affect platelet function.
NSAIDs: ibuprofen, naproxen, indomethacin.
Cardiovascular agents:
Calcium channel blockers: nifedipine, diltiazem, verapamil.
β-Blockers: propranolol.
Vasodilators: nitrates, nitroprusside.
Diuretics: furosemide.
Angiotensin II receptor antagonist: losartan, valsartan, and olmesartan.
Antibiotics: β-lactams, amphotericin, hydroxychloroquine, nitrofurantoin.
Antifungal drugs: Miconazole, amphotericin B:
Psychiatric drugs: TCAs, fluoxetine, chlorpromazine, promethazine, trifluoperazine.
Oncologic drugs: mithramycin, daunorubicin, BCNU, asparaginase, vincristine, dasatinib, ibrutinib.
Anesthetics: dibucaine, procaine, halothane, sevoflurane, propofol.
Plasma expanders: dextran, hydroxyl ethyl starch.
Heparins and thrombolytic agents.
Miscellaneous: clofibrate, statins, cocaine, ketanserin, radiographic contrast agents, antihistamines, immunosuppressive drugs.

ADP, Adenosine diphosphate; *BCNU,* carmustine; *COX,* cyclooxygenase; *NSAID,* nonsteroidal antiinflammatory drug; *PDE,* phosphodiesterase; *TCA,* tricyclic antidepressant.

PLEURAL EFFUSIONS

ICD-10CM #	J91.8	Pleural effusion in other conditions classified elsewhere

EXUDATIVE

Neoplasm: bronchogenic carcinoma, breast carcinoma, mesothelioma, lymphoma, ovarian carcinoma, multiple myeloma, leukemia, Meigs syndrome.
Infections: viral pneumonia, bacterial pneumonia, *Mycoplasma,* TB, fungal and parasitic diseases, extension from subphrenic abscess.
Trauma.
Collagen vascular diseases: SLE, RA, scleroderma, polyarteritis, granulomatosis with polyangiitis.
Pulmonary infarction.
Pancreatitis.
Postcardiotomy/Dressler syndrome.
Drug-induced SLE (hydralazine, procainamide).
Postabdominal surgery.
Ruptured esophagus.
Chronic effusion secondary to congestive failure.

TRANSUDATIVE

CHF.
Hepatic cirrhosis.
Nephrotic syndrome.
Hypoproteinemia from any cause.
Meigs syndrome.

PLEURAL EFFUSIONS, MALIGNANCY-ASSOCIATED

ICD-10CM #	C78.2	Secondary malignant neoplasm of pleura

Lung cancer	(30% to 40%)
Breast cancer	(20% to 25%)
Lymphoma	(10% to 15%)
Leukemia	(5% to 10%)
GI tract	(5%)
GU tract	(5%)
Reproductive	(3%)

PLEURAL HYPERPLASIA[77]

ICD-10CM #	Varies with specific diagnosis

BENIGN CAUSES OF PLEURAL HYPERPLASIA

Pleural infections.
Radiation.
Surgery.
Trauma.
Intracavitary treatments (chemotherapy or sclerosing agents).
Collagen vascular diseases.
Systemic immune diseases (systemic lupus erythematosus, rheumatoid arthritis, Sjögren syndrome, Wegener granulomatosis).
Subpleural pulmonary abnormalities (infarction, infection, neoplasia).
Pneumothorax.
Drug reactions (nitrofurantoin, bromocriptine, methysergide, procarbazine).
Pancreatitis, uremia.
Pneumoconiosis (asbestosis).

PLEURAL MASSES[77]

ICD-10CM # Varies with specific diagnosis

CAUSES OF PLEURAL MASSES

Inflammatory pleural reactions:
- Reactive mesothelial hyperplasia or organizing pleuritis versus atypical mesothelial hyperplasia.
- Nodular pleural plaques.

Pulmonary tumors that may resemble pleural tumors:
- Inflammatory pseudotumor of the lung.

Benign pleural tumors:
- Solitary fibrous tumor.
- Lipomas and lipoblastomas.
- Adenomatous tumors.
- Calcifying fibrous tumors.
- Mesothelial cysts.
- Multicystic mesothelioma.
- Schwannoma.

Pleural tumors with low malignant potential:
- Desmoid tumors.
- Well-differentiated papillary mesothelioma.
- Pleural thymoma.

Primary malignant pleural tumors that may look like benign tumors:
- Malignant solitary fibrous tumor.
- Pleuropulmonary blastoma.
- Localized malignant mesothelioma.
- Vascular sarcoma.
- Liposarcoma.
- Pleuropulmonary synovial sarcoma.
- Askin tumor or primitive neuroectodermal tumor (PNET).
- Desmoplastic small round cell tumor.

Malignant pleural tumors:
- Metastatic malignancies to the pleura.
- Malignant mesothelioma.

PNEUMATOSIS INTESTINALIS IN NEONATE AND OLDER CHILD[36]

ICD-10CM # Varies with specific diagnosis

CAUSES OF PNEUMATOSIS INTESTINALIS IN THE NEONATE AND THE OLDER CHILD

Necrotizing enterocolitis.
Bowel ischemia, inflammation, and obstruction.
Cyanotic congenital heart disease.
Hirschsprung disease.
Gastroschisis.
Anorectal atresia.
Inflammatory bowel disease.
Lymphoma.
Leukemia.
CMV and rotavirus gastroenteritis.
Colonoscopy.
Caustic ingestion.
Short bowel syndrome.
Congenital immune deficiency states.
Clostridium infection.
Chronic steroid use.
Posthepatic, renal, or bone marrow transplant.
Collagen vascular disease.
Graft-versus-host disease.
AIDS.

PNEUMONIA, CHRONIC[10]

ICD-10CM #

J15.9	Unspecified bacterial pneumonia
J12.9	Viral pneumonia, unspecified
B25.0	Cytomegaloviral pneumonitis
J18.0	Bronchopneumonia, unspecified organism

INFECTIOUS AGENTS THAT TYPICALLY CAUSE CHRONIC PNEUMONIA

Bacteria
Mixed aerobic and anaerobic bacteria.
Actinomyces spp.
Nocardia spp.
Rhodococcus equi.
Burkholderia pseudomallei.
Mycobacteria
Mycobacterium tuberculosis.
Mycobacterium kansasii.
Mycobacterium avium complex.
Mycobacterium abscessus.
Mycobacterium terrae.
Fungi
Aspergillus spp.
Blastomyces dermatitidis.
Coccidioides spp.
Cryptococcus neoformans.
Cryptococcus gattii.
Dark-walled molds.
Emmonsia parvum var. *crescens.*
Histoplasma capsulatum.
Sporothrix schenckii complex.
Paracoccidioides brasiliensis.
Penicillium marneffei.
Scedosporium apiospermum.
Parasites
Dirofilaria:
- *Echinococcus granulosus.*
- *Filaria (tropical pulmonary eosinophilia).*
- *Paragonimus westermani.*

NONINFECTIOUS CAUSES OF CHRONIC PNEUMONIA

Neoplasia
Carcinoma (primary or metastatic).
Hodgkin disease and non-Hodgkin lymphoma.
Other lymphoproliferative disorders.
Cystic Fibrosis
Sarcoidosis
Amyloidosis
Vasculitis (Autoimmune Diseases)
Systemic lupus erythematosus.
Polyarteritis nodosa.
Granulomatosis with polyangiitis.
Allergic angiitis and granulomatosis (Churg-Strauss syndrome).
Goodpasture syndrome.
Microscopic polyangiitis.
Lymphomatoid granulomatosis.
Progressive systemic sclerosis.
Rheumatoid arthritis.
Mixed connective tissue syndrome (overlap syndrome).
Chemicals, Drugs
Radiation
Recurrent Pulmonary Emboli
Bronchial Obstruction with Atelectasis (e.g., Tumor, Foreign Body)
Pulmonary sequestration
Pulmonary infiltration with eosinophilia syndrome (Löffler syndrome—usually transient.)
Pneumonia plus asthma (e.g., allergic bronchopulmonary aspergillosis).
Bronchocentric granulomatosis.
Chronic eosinophilic pneumonia.
Pneumoconiosis
Asbestosis.
Berylliosis.
Silicosis.
Anthracosilicosis.
Chronic Form of Extrinsic Allergic Alveolitis (Hypersensitivity Pneumonitis)

OTHER LUNG DISEASES: CAUSE UNKNOWN

Chronic Organizing Pneumonia
Chronic Interstitial Pneumonia (Fibrosing Alveolitis, Idiopathic Pulmonary Fibrosis)
Usual interstitial pneumonia (UIP).
Desquamative interstitial pneumonia (DIP).
Lymphocytic interstitial pneumonia (LIP).
Giant cell interstitial pneumonia (GIP).
Eosinophilic granuloma (histiocytosis X).
Lymphangioleiomyomatosis.
Pulmonary alveolar proteinosis.
Pulmonary alveolar microlithiasis.
Idiopathic pulmonary hemosiderosis.
Angiocentric immunoproliferative lesions.

PNEUMONIA MIMICS[13]

ICD-10CM # Varies with specific diagnosis

NONINFECTIOUS CAUSES THAT MAY PRESENT AS PNEUMONIA

Radiologic Technique
Inadequate inspiration.
Breast shadow.
Thymus.
Uneven grid on film.
Underpenetrated film.
Primary Pulmonary
Asthma.
Bronchiectasis.
Atelectasis.
Bronchopulmonary dysplasia.
Cystic fibrosis.
Pulmonary sequestration.
Congenital cystic adenomatoid malformation.
α_1-Antitrypsin deficiency.
Aspiration
Foreign body.
Chemical.
Recurrent caused by anatomic or physiologic disorders.
Primary Cardiac
Congenital heart disease.
CHF
Pulmonary Infarction
Sickle cell vasoocclusive crisis.
Pulmonary embolism.

Collagen Vascular Disorders
Acute Respiratory Distress Syndrome
Pleural effusion
Neoplasm.

PNEUMONIA, NONRESPONDING, CAUSES[61]

ICD-10CM #	J15.9	Unspecified bacterial pneumonia
	J12.9	Viral pneumonia, unspecified
	B25.0	Cytomegaloviral pneumonitis
	J18.0	Bronchopneumonia, unspecified organism

CAUSES OF NONRESPONDING PNEUMONIA

Infectious Pneumonia
Resistant microorganisms:
- Community-acquired pneumonia (e.g., *Streptococcus pneumoniae, Staphylococcus aureus*).
- *Nosocomial pneumonia* (e.g., *Acinetobacter*, methicillin-resistant *Staphylococcus aureus* (MRSA), *Pseudomonas aeruginosa*).

Uncommon microorganisms (e.g., *Mycobacterium tuberculosis, Nocardia* spp., fungi, *Pneumocystis jirovecii*).
Complications of pneumonia:
Empyema.
Abscess or necrotizing pneumonia.
Metastatic infection.
Noninfectious Pneumonia
Neoplasms.
Pulmonary hemorrhage.
Pulmonary embolism.
Sarcoidosis.
Eosinophilic pneumonia.
Pulmonary edema.
Acute respiratory distress syndrome.
Bronchiolitis obliterans with organizing pneumonia.
Drug-induced pulmonary disease.
Pulmonary vasculitis.

PNEUMONIA, RECURRENT

ICD-10CM #	J15.9	Unspecified bacterial pneumonia
	J12.9	Viral pneumonia, unspecified
	B25.0	Cytomegaloviral pneumonitis
	J18.0	Bronchopneumonia, unspecified organism

Mechanical obstruction from neoplasm.
Chronic aspiration (tube feeding, alcoholism, CVA, neuromuscular disorders, seizure disorder, inability to cough).
Bronchiectasis.
Kyphoscoliosis.
COPD, CHF, asthma, silicosis, pulmonary fibrosis, cystic fibrosis.
Pulmonary TB, chronic sinusitis.
Immunosuppression (HIV, corticosteroids, leukemia, chemotherapy, splenectomy).

PNEUMOPERITONEUM, NEONATAL[36]

ICD-10CM # Varies with specific diagnosis

CAUSES OF NEONATAL PNEUMOPERITONEUM

Necrotizing enterocolitis.
Spontaneous perforation of a hollow viscus:
- Stomach.
- Duodenum.
- Ileum.
- Colon.

Malrotation and volvulus.
Distal obstruction.
Perforation of Meckel diverticulum.
Anterior abdominal wall defects:
- Pentalogy of Cantrell.
- Omphalocele.
- Gastroschisis.
- Cloacal exstrophy.

Stress and peptic ulcers.
Mechanical ventilation (air leak) or resuscitation ("bagging").
Post-laparotomy.
Iatrogenic gastric perforation with an orogastric tube.
Iatrogenic colon perforation:
- Thermometer.
- During an enema.

Indomethacin.
Dexamethasone treatment.

PNEUMOTHORAX, IN CHILDREN[53]

ICD-10CM #	J93.0	Spontaneous tension pneumothorax
	J93	Pneumothorax
	J93.9	Pneumothorax unspecified

SPONTANEOUS

Primary idiopathic—usually resulting from ruptured subpleural blebs.
Secondary blebs.
Congenital lung disease:
- Congenital cystic adenomatoid malformation.
- Bronchogenic cysts.
- Pulmonary hypoplasia.

Conditions associated with increased intrathoracic pressure:
- Asthma.
- Bronchiolitis.
- Air-block syndrome in neonates.
- Cystic fibrosis.
- Airway foreign body.

Infection:
- Pneumatocele.
- Lung abscess.
- Bronchopleural fistula.

Diffuse lung disease:
- Langerhans cell histiocytosis.
- Tuberous sclerosis.
- Marfan syndrome.
- Ehlers-Danlos syndrome.

Metastatic neoplasm—usually osteosarcoma (rare).

TRAUMATIC

Noniatrogenic:
- Penetrating trauma.
- Blunt trauma.
- Loud music (air pressure).

Iatrogenic:
- Thoracotomy.
- Thoracoscopy, thoracentesis.
- Tracheostomy.
- Tube or needle puncture.

Mechanical ventilation.

POLIOSIS[12]

ICD-10CM # Varies with specific diagnosis

CAUSES OF POLIOSIS

Ocular
Chronic anterior blepharitis.
Sympathetic ophthalmitis.
Idiopathic uveitis.
Systemic
Vogt–Koyanagi–Harada syndrome.
Waardenburg syndrome.
Vitiligo.
Marfan syndrome.
Tuberous sclerosis.

POLYCYTHEMIA

ICD-10CM #	D45	Polycythemia primary
	D75.1	Polycythemia secondary

Tobacco abuse.
Chronic lung disease.
High altitude.
Sleep apnea.
Right-to-left cardiac shunts.
Erythropoietin administration.
Androgens/anabolic steroids.
Polycystic kidney disease.
Renal cell carcinoma.
Hepatocellular carcinoma.
Polycythemia vera.
Carbon monoxide exposure.
Primary familial and congenital polycythemia.
High-oxygen–affinity hemoglobins.
Uterine leiomyoma, meningioma, pheochromocytoma, parathyroid carcinoma.
Cobalt exposure.

POLYCYTHEMIAS, DIFFERENTIAL DIAGNOSIS[44]

ICD-10CM #	D45	Polycythemia primary
	D75.1	Polycythemia secondary

DIFFERENTIAL DIAGNOSIS OF THE POLYCYTHEMIAS

Relative or Spurious Polycythemia
Decreased plasma volume—reduced fluid intake, marked loss of body fluids (diaphoresis, vomiting, diarrhea, "third spacing").

Gaisböck syndrome.
Overfilling of blood in collection vacuum tubes.
Absolute polycythemia
Secondary polycythemia.
Acquired.
Hypoxia:
  Pulmonary disease.
  Cyanotic congenital heart disease.
  Hypoventilation syndromes:
    Sleep apnea.
    Pickwickian syndrome.
    High altitude.
    Smokers' polycythemia, hookah polycythemia, carbon monoxide intoxication caused by industrial exposure.
Postrenal transplantation erythrocytosis.
Aberrant erythropoietin production.
Tumors:
  Renal cell carcinoma.
  Wilms tumor.
  Hepatic carcinoma.
  Uterine leiomyomata.
Virilizing ovarian tumors.
Vascular cerebellar tumors.
Miscellaneous renal and hepatic disorders:
  Solitary renal cysts.
  Polycystic kidney disease.
  Renal artery stenosis hydronephrosis.
  Viral hepatitis.
  Endocrine disorders:
  Cushing syndrome.
  Primary aldosteronism.
  Androgen use.
  Erythropoietin use.
  Congenital polycythemias:
    Abnormal high-affinity hemoglobin variants.
    Bisphosphoglycerate deficiency.
    Congenital methemoglobinemia.
    Chuvash polycythemia (von Hippel Lindau mutations).
    Prolyl hydroxylase mutations.
    Hypoxia-inducible factor gene mutations.
Primary polycythemias:
  Primary congenital and familial polycythemia.
  Polycythemia vera.

POLYCYTHEMIA, RELATIVE VERSUS ABSOLUTE[45]

ICD-10CM # D75.1 Secondary polycythemia

RELATIVE OR SPURIOUS POLYCYTHEMIA

Decreased plasma volume—reduced fluid intake, marked loss of body fluids (diaphoresis, vomiting, diarrhea, "third-spacing").
Gaisböck syndrome.
Overfilling of blood in collection vacuum tubes.

ABSOLUTE POLYCYTHEMIA

Primary Congenital and Familial Polycythemia
Secondary Polycythemia Acquired
Hypoxia:
  Pulmonary disease.
  Cyanotic congenital heart disease.
  Hypoventilation syndromes: sleep apnea, Pickwickian syndrome.
  High altitude.
  Smokers' polycythemia, carbon monoxide intoxication due to industrial exposure.
Postrenal transplantation erythrocytosis.
Aberrant erythropoietin production.
Tumors: renal cell carcinoma, Wilms tumor, hepatic carcinoma, uterine leiomyomata, virilizing ovarian tumors, vascular cerebellar tumors.
Miscellaneous renal and hepatic disorders: solitary renal cysts, polycystic kidney disease, renal artery stenosis, hydronephrosis, viral hepatitis.
Endocrine disorders: Cushing syndrome, primary aldosteronism.
Androgen use.
Erythropoietin use.
Congenital:
  Abnormal high-affinity hemoglobin variants.
  Bisphosphoglycerate deficiency.
  Congenital methemoglobinemia.
  Chuvash polycythemia (von Hippel–Lindau mutations).
  Prolyl hydroxylase mutations.

POLYCYTHEMIA VERA

POLYMYALGIAS[41]

ICD-10CM # M35.3 Polymyalgia rheumatica

DISEASE ENTITIES WITH POLYMYALGIAS

Rheumatoid arthritis.
Rotator cuff syndrome.
Osteoarthritis of shoulder and hip joints.
Fibromyalgia.
Polymyositis/dermatomyositis.
Spondyloarthritis.
Systemic lupus erythematosus.
Vasculitides.
Paraneoplastic myalgias.
Infection-associated myalgias.
Statin therapy.
RS3PE (remitting seronegative symmetric synovitis and pitting edema).
Parkinson disease.
Hypothyroidism.

POLYNEUROPATHY[93]

ICD-10CM # G61.9 Inflammatory polyneuropathy, unspecified

PREDOMINANTLY MOTOR

Guillain-Barré syndrome.
Porphyria.
Diphtheria.
Lead.
Hereditary sensorimotor neuropathy, types I and II.
Paraneoplastic neuropathy.

PREDOMINANTLY SENSORY

Diabetes.
Amyloidosis.
Leprosy.
Lyme disease.
Paraneoplastic neuropathy.
Vitamin B_{12} deficiency.
Hereditary sensory neuropathy, types I-IV.

PREDOMINANTLY AUTONOMIC

Diabetes.
Amyloidosis.
Alcoholic neuropathy.
Familial dysautonomias.

MIXED SENSORIMOTOR

Systemic diseases: renal failure, hypothyroidism, acromegaly, RA, periarteritis nodosa, SLE, multiple myeloma, macroglobulinemia, remote effect of malignancy.
Medications: isoniazid, nitrofurantoin, ethambutol, chloramphenicol, chloroquine, vincristine, vinblastine, dapsone, disulfiram, diphenylhydantoin, cisplatin, 1-tryptophan.
Environmental toxins: *N*-hexane, methyl *N*-butyl ketone, acrylamide, carbon disulfide, carbon monoxide, hexachlorophene, organophosphates.
Deficiency disorders: malabsorption, alcoholism, vitamin B_1 deficiency, Refsum disease, metachromatic leukodystrophy.

POLYNEUROPATHY, DEMYELINATING[7]

ICD-10CM # G37.9 Demyelinating disease of central nervous system, unspecified

Guillain-Barré syndrome:
  Acute inflammatory demyelinating polyradiculoneuropathy (AIDP).
  Acute motor axonal neuropathy (AMAN).
  Acute motor and sensory axonal neuropathy (AMSAN).
  Miller Fisher syndrome.
Chronic inflammatory demyelinating polyradiculoplexo-neuropathy.
Malignancy.
HIV.
Hepatitis B.
Buckthorn.
Diphtheria.

POLYNEUROPATHY, DISTAL SENSORIMOTOR[7]

ICD-10CM # G63 Polyneuropathy in diseases classified elsewhere

Diabetes mellitus.
Alcoholism.
Neoplastic or paraneoplastic.
Hereditary motor and sensory neuropathies (Charcot-Marie-Tooth).
Cryptogenic sensorimotor polyneuropathies (CSPN).
HIV.
Toxins:
  Organic or industrial agents:
    Acrylamide.
    Allyl chloride.
    Carbon disulfide.
    Ethylene oxide.
    Hexacarbons.
    Methyl bromide.

Organophosphate-induced delayed polyneuropathy (OPIDP).
Polychlorinated biphenyls (PCBs).
Trichloroethylene.
Vacor.
Metals:
Arsenic.
Gold.
Mercury (inorganic).
Thallium.
Therapeutic agents:
Amiodarone.
Antiretrovirals.
Dapsone.
Disulfiram.
Isoniazid.
Metronidazole.
Nitrofurantoin.
Paclitaxel (Taxol).
Phenytoin.
Statins (HMG-CoA reductase inhibitors).
Thalidomide.
Vinca alkaloids (vincristine, vinblastine).
Nutritional:
Beriberi (thiamine or vitamin B_1).
Pellagra (niacin, B vitamins).
Pernicious anemia (vitamin B_{12}).
Pyridoxine deficiency (vitamin B_6).
End-organ dysfunction
Acromegaly.
Chronic pulmonary disease.
Hypothyroidism.
Renal failure (uremic neuropathy).
Paraproteinemias:
Amyloidosis.
Monoclonal gammopathy of unknown significance (MGUS).
Multiple myeloma.
Waldenström macroglobulinemia.
Porphyria.

HMG-CoA, Hydroxymethylglutaryl coenzyme A.

POLYNEUROPATHY, DRUG-INDUCED[93]

ICD-10CM #	G62.0	Drug-induced polyneuropathy

DRUGS IN ONCOLOGY

Vincristine.
Procarbazine.
Cisplatin.
Misonidazole.
Metronidazole
Taxol.

DRUGS IN INFECTIOUS DISEASES

Isoniazid.
Nitrofurantoin.
Dapsone.
ddC (dideoxycytidine).
ddI (dideoxyinosine).

DRUGS IN CARDIOLOGY

Hydralazine.
Perhexiline maleate.
Procainamide.
Disopyramide.

DRUGS IN RHEUMATOLOGY

Gold salts.
Chloroquine.

DRUGS IN NEUROLOGY AND PSYCHIATRY

Diphenylhydantoin.
Glutethimide.
Methaqualone.

MISCELLANEOUS

Disulfiram (Antabuse).
Vitamin: (pyridoxine in megadoses).

POLYNEUROPATHY, SYMMETRIC[93]

ICD-10CM #	G61.9	Inflammatory polyneuropathy, unspecified

ACQUIRED NEUROPATHIES

Toxic:
Drugs.
Industrial toxins.
Heavy metals.
Abused substances.
Metabolic/endocrine:
Diabetes.
Chronic renal failure.
Hypothyroidism.
Polyneuropathy of critical illness.
Nutritional deficiency:
Vitamin B_{12} deficiency.
Alcoholism.
Vitamin E deficiency.
Paraneoplastic:
Carcinoma.
Lymphoma.
Plasma cell dyscrasia:
Myeloma, typical, atypical, and solitary forms.
Primary systemic amyloidosis.
Idiopathic chronic inflammatory demyelinating polyneuropathies.
Polyneuropathies associated with peripheral nerve autoantibodies.
AIDS.

INHERITED NEUROPATHIES

Neuropathies with Biochemical Markers
Refsum disease.
Bassen-Kornzweig disease.
Tangier disease.
Metachromatic leukodystrophy.
Krabbe disease.
Adrenomyeloneuropathy.
Fabry disease.
Neuropathies without Biochemical Markers or Systemic Involvement
Hereditary motor neuropathy.
Hereditary sensory neuropathy.
Hereditary sensorimotor neuropathy.

POLYURIA

ICD-10CM #	R35.8	Other polyuria

DM.
Diabetes insipidus.
Primary polydipsia (compulsive water drinking).
Hypercalcemia.
Hypokalemia.
Postobstructive uropathy.
Diuretic phase of renal failure.
Drugs: diuretics, caffeine, alcohol, lithium.
Sickle cell trait or disease, chronic pyelonephritis (failure to concentrate urine).
Anxiety, cold weather.

POPLITEAL SWELLING

ICD-10CM#	I87.1	Compression of vein
	I72.4	Aneurysm of artery of lower extremity
	S85.009A	Unspecified injury of popliteal artery, unspecified leg, initial encounter
	I77.3	Arterial fibromuscular dysplasia
	M71.20	Synovial cyst of popliteal space [Baker], unspecified knee
	I80.3	Phlebitis and thrombophlebitis of lower extremities, unspecified
	M66.369	Spontaneous rupture of flexor tendons, unspecified lower leg

Phlebitis (superficial).
Lymphadenitis.
Trauma: fractured tibia or fibula, contusion, traumatic neuroma.
DVT.
Ruptured varicose vein.
Baker cyst.
Popliteal abscess.
Osteomyelitis.
Ruptured tendon.
Aneurysm of popliteal artery.
Neoplasm: lipoma, osteogenic sarcoma, neurofibroma, fibrosarcoma.

PORTAL HYPERTENSION[3]

ICD-10CM #	K76.6	Portal hypertension

INCREASED RESISTANCE TO FLOW

Presinusoidal
Portal or splenic vein occlusion (thrombosis, tumor).
Schistosomiasis.
Congenital hepatic fibrosis.
Sarcoidosis.
Sinusoidal
Cirrhosis (all causes).
Alcoholic hepatitis.
Postsinusoidal
Venoocclusive disease.
Budd-Chiari syndrome.
Constrictive pericarditis.

INCREASED PORTAL BLOOD FLOW

Splenomegaly not caused by liver disease.
Arterioportal fistula.

POSTMENOPAUSAL BLEEDING

ICD-10CM # N95.0 Postmenopausal bleeding

Hormone replacement therapy.
Neoplasm (uterine, ovarian, cervical, vaginal, vulvar).
Atrophic vaginitis.
Vaginal infection.
Polyp.
Extragenital (GI, urinary).
Tamoxifen.
Trauma.

POSTURAL HYPOTENSION, NONNEUROLOGIC CAUSES

ICD-10CM # I95.1 Orthostatic hypotension

Diuretics and hypertensive agents.
GI hemorrhage.
Alcohol.
Excessive heat.
Rapid volume loss from diarrhea, vomiting.
Hemodialysis.
Extensive burns.
Pyrexia.
Aortic stenosis (impaired output).
Constrictive pericarditis, atrial myxoma (impaired cardiac filling).
Adrenal insufficiency.
Diabetes insipidus.
Vasodilatory agents (e.g., nitrates).

PREMATURE GRAYING, SCALP HAIR

ICD-10CM # Varies with specific diagnosis

Chemical exposure (e.g., phenol/catechol derivatives, sulfhydryls, arsenic).
Physical agents (e.g., ionizing radiation, lasers).
Hyperthyroidism.
Vitamin B_{12} deficiency.
Down syndrome.
Chronic and severe protein deficiency.
Vitiligo.
Idiopathic.
Myotonic dystrophy.
Ataxia-telangiectasia.
Progeria.
Werner syndrome.

PREMATURE VENTRICULAR CONTRACTIONS AND VENTRICULAR TACHYCARDIA[7]

ICD-10CM #		
	I49.40	Unspecified premature depolarization
	I47.2	Ventricular tachycardia

CAUSES OF PREMATURE VENTRICULAR CONTRACTIONS AND VENTRICULAR TACHYCARDIA

Acute or previous myocardial infarction/ischemia.
Hypokalemia.
Hypoxemia.
Ischemic heart disease.
Valvular disease.
Catecholamine excess.[34]
Other drug intoxications (especially cyclic antidepressants).
Idiopathic causes.[35]
Digitalis toxicity.
Hypomagnesemia.
Hypercapnia.
Class I antidysrhythmic agents.
Ethanol.
Myocardial contusion.
Cardiomyopathy.
Acidosis.
Alkalosis.
Methylxanthine toxicity.

[34] Relative increase in sympathetic tone from drugs (direct or indirect) or conditions that augment catecholamine release or decrease parasympathetic tone.

[35] Isolated premature ventricular contractions (PVCs) can occur in up to 50% of young subjects without obvious cardiac or noncardiac disease; however, multiform and repetitive PVCs and ventricular tachycardia are rarely seen in this population.

PRESACRAL MASSES IN CHILDREN[74]

ICD-10CM # Varies with specific diagnosis

PRESACRAL MASSES IN CHILDREN

Solid
Sacrococcygeal teratoma.
Neuroblastoma.
Rhabdomyosarcoma.
Fibroma.
Lipoma.
Leiomyoma.
Lymphoma.
Hemangioendothelioma.
Sacral bone tumors.
Cystic
Abscess.
Rectal duplication.
Hematoma.
Lymphocele.
Neurenteric cyst.
Sacral osteomyelitis.
Ulcerative colitis.
Anterior meningocele.

PROLONGED QT SYNDROMES[60]

ICD-10CM # I45.81 Long QT syndrome

CLASSIFICATION AND CAUSES OF PROLONGED QT SYNDROMES THAT PRODUCE TORSADES DE POINTES

Pause Dependent (Acquired)
Drug induced: class IA and IC antidysrhythmics; many phenothiazines and butyrophenones (notably haloperidol and droperidol), cyclic antidepressants, antibiotics (especially macrolides), organophosphates, antihistamines, antifungals, antiseizure and antiemetic agents.
Electrolyte abnormalities: hypokalemia, hypomagnesemia, hypocalcemia (rarely).
Diet related: starvation, low protein.
Severe bradycardia or atrioventricular block.
Hypothyroidism.
Contrast injection.
Cerebrovascular accident (especially intraparenchymal).
Myocardial ischemia.
Adrenergic Dependent (Tachycardia Prompted)
Congenital:
- Jervell and Lange-Nielsen syndrome (deafness, autosomal recessive).
- Romano-Ward syndrome (normal hearing, autosomal dominant).
- Sporadic (normal hearing, no familial tendency).
- Mitral valve prolapse.

Acquired (Rare):
- Cerebrovascular disease (especially subarachnoid hemorrhage).
- Autonomic surgery: radical neck dissection, carotid endarterectomy, truncal vagotomy.

PROPTOSIS[67]

ICD-10CM #		
	H05.20	Unspecified exophthalmos
	H05.2	Ocular proptosis

Thyrotoxicosis.
Orbital pseudotumor.
Optic nerve tumor.
Cavernous sinus AV fistula, cavernous sinus thrombosis.
Cellulitis.
Metastatic tumor to orbit.

PROPTOSIS AND PALATAL NECROTIC ULCERS

ICD-10CM #		
	K13.70	Unspecified lesions of oral mucosa
	K13.79	Other lesions of oral mucosa
	H05.20	Unspecified exophthalmos

Cavernous sinus thrombosis.
Bacterial orbital cellulitis.
Metastatic neoplasm.
Rhinocerebral mucormycosis.
Ecthyma gangrenosum.
CNS aspergillosis.

PROTEIN-LOSING ENTEROPATHY, PEDIATRIC AGE[53]

ICD-10CM # E44.0 Moderate protein-energy malnutrition

CAUSES OF PROTEIN-LOSING ENTEROPATHY

Mucosal inflammation:
Infection:

Cytomegalovirus.
Bacterial overgrowth.
Invasive bacterial infection.
Gastric inflammation:
Ménétrier disease.
Eosinophilic gastroenteropathy.
Intestinal inflammation:
Celiac disease.
Crohn disease.
Eosinophilic gastroenteropathy:
Tropical sprue.
Radiation enteritis.
Primary intestinal lymphangiectasia.
Secondary intestinal lymphangiectasia:
Constrictive pericarditis.
Congestive heart failure.
Post–Fontan procedure.
Malrotation.
Lymphoma.
Sarcoidosis.
Radiation therapy.
Colonic inflammation:
Inflammatory bowel diseases.
Necrotizing enterocolitis.
Congenital disorders of glycosylation.

PROTEINURIA

ICD-10CM # R80.9 Proteinuria, unspecified

Nephrotic syndrome as a result of primary renal diseases.
Malignant hypertension.
Malignancies: multiple myeloma, leukemias, Hodgkin disease.
CHF.
DM.
SLE, RA.
Sickle cell disease.
Goodpasture syndrome.
Malaria.
Amyloidosis, sarcoidosis.
Tubular lesions: cystinosis.
Functional (after heavy exercise).
Pyelonephritis.
Pregnancy.
Constrictive pericarditis.
Renal vein thrombosis.
Toxic nephropathies: heavy metals, drugs.
Radiation nephritis.
Orthostatic (postural) proteinuria.
Benign proteinuria: fever, heat, or cold exposure.

PRURITUS

ICD-10CM #	L29.9	Pruritus, unspecified
	L29.3	Anogenital pruritus, unspecified

Dry skin.
Drug-induced eruption, fiberglass exposure.
Scabies.
Skin diseases.
Myeloproliferative disorders: mycosis fungoides, Hodgkin lymphoma, multiple myeloma, polycythemia vera.
Cholestatic liver disease.
Endocrine disorders: DM, thyroid disease, carcinoid, pregnancy.
Carcinoma: breast, lung, gastric.
Chronic renal failure.
Iron deficiency.
AIDS.
Neurosis.
Sjögren syndrome.

PRURITUS ANI[60]

ICD-10CM # L29.0 Pruritus ani

FECAL IRRITATION

Poor hygiene.
Anorectal conditions (fissure, fistula, hemorrhoids, skin tags, perianal clefts).
Spicy foods, citrus foods, caffeine, colchicine, quinidine.

CONTACT DERMATITIS

Anesthetic agents, topical corticosteroids, perfumed soap.

DERMATOLOGIC DISORDERS

Psoriasis, seborrhea, lichen simplex or sclerosus.

SYSTEMIC DISORDERS

Chronic renal failure, myxedema, DM, thyrotoxicosis, polycythemia vera, Hodgkin disease.

SEXUALLY TRANSMITTED DISEASES

Syphilis, herpes simplex virus, human papillomavirus.

OTHER INFECTIOUS AGENTS

Pinworms.
Scabies.
Bacterial infection, viral infection.

PRURITUS VULVAE[80]

ICD-10CM #	L29.3	Anogenital pruritus, unspecified

CAUSES OF PRURITUS VULVAE

Diseases Special to Vulval Skin
Lichen sclerosus et atrophicus.
Leukoplakia.
Carcinoma.
Skin Disease
Psoriasis.
Atopic dermatitis.
Irritant and allergic contact dermatitis (especially medicaments).
Infection
Candidiasis.
Trichomonas.
Infestation
Pediculosis.
Psychogenic
Anxiety.
Depression.
Unknown

PSEUDOCYANOSIS, ETIOLOGY

ICD-10CM # Varies with etiology

Medications: amiodarone, minocycline, chlorpromazine.
Heavy metals:
Gold (systemic absorption).
Silver (systemic absorption).
Local contact with color dyes, gold, silver.

PSEUDOHERMAPHRODITISM, FEMALE

ICD-10CM #	E25.0	Congenital adrenogenital disorders associated with enzyme deficiency
	E25.8	Other adrenogenital disorders
	E25.9	Adrenogenital disorder, unspecified
	Q56.3	Pseudohermaphroditism, unspecified
	Q56.4	Indeterminate sex, unspecified

Congenital adrenal hyperplasia.
Maternal use of testosterone or related steroids.
Virilizing ovarian or adrenal tumor.
Virilizing luteoma of pregnancy.
Disturbances in differentiation of urogenital structures, non-androgen related.
Maternal virilizing adrenal hyperplasia.
Fetal P450 aromatase deficiency.

PSEUDOHERMAPHRODITISM, MALE

ICD-10CM#	E25.0	Congenital adrenogenital disorders associated with enzyme deficiency
	E25.8	Other adrenogenital disorders
	E25.9	Adrenogenital disorder, unspecified
	Q56.3	Pseudohermaphroditism, unspecified
	Q56.4	Indeterminate sex, unspecified

Maternal ingestion of progestogens.
End-organ resistance to androgenic hormones.
5-α-reductase-2 deficiency.
XY gonadal dysgenesis.
Testicular regression syndrome.
Defects in testosterone metabolism by peripheral tissues.
Testosterone biosynthesis defects.

PSEUDOINFARCTION[52]

ICD-10CM # Varies with specific diagnosis

Cardiac tumors, primary and secondary.
Cardiomyopathy (particularly hypertrophic and dilated).
Chagas disease.
Chest deformity.
COPD (particularly emphysema).
HIV infection.
Hyperkalemia.
Left anterior fascicular block.
Left bundle branch block.

Left ventricular hypertrophy.
Myocarditis and pericarditis.
Normal variant.
Pneumothorax.
Poor R wave progression, rotational changes, and lead placement.
Pulmonary embolism.
Trauma to chest (nonpenetrating).
Wolff-Parkinson-White syndrome.
Rare causes: pancreatitis, amyloidosis, sarcoidosis, scleroderma.

PSYCHOSIS[65]

ICD-10CM #	F29	Unspecified psychosis not due to a substance or known physiological condition
	F29	Unspecified psychosis not due to a substance or known physiological condition
	F10.231	Alcohol dependence with withdrawal delirium
	F01.51	Vascular dementia with behavioral disturbance

PRIMARY

Schizophrenia-related.[36]
Major depression.
Dementia.
Bipolar disorder.

SECONDARY

Drug use.[37]
Drug withdrawal.[38]
Drug toxicity.[39]
Charles Bonnet syndrome.
Infections (pneumonia).
Electrolyte imbalance.
Syphilis.
Congestive heart failure.
Parkinson disease.
Trauma to temporal lobe.
Postpartum psychosis.
Hypothyroidism/hyperthyroidism.
Hypomagnesemia.
Epilepsy.
Meningitis.
Encephalitis.
Brain abscess.
Herpes encephalopathy.
Hypoxia.
Hypercarbia.
Hypoglycemia.
Thiamine deficiency.
Postoperative states.

[36] Includes schizophrenia, schizophreniform disorder, brief reactive psychosis.
[37] Includes hypnotics, glucocorticoids, marijuana, phencyclidine, atropine, dopaminergic agents (e.g., amantadine, bromocriptine, L-dopa), immunosuppressants.
[38] Includes alcohol, barbiturates, benzodiazepines.
[39] Includes digitalis, theophylline, cimetidine, anticholinergics, glucocorticoids, catecholaminergic agents.

PSYCHOSIS, MEDICAL DISORDERS-INDUCED[60]

ICD-10CM #	F29	Unspecified psychosis not due to a substance or known physiological condition
	F53	Puerperal psychosis

MEDICAL DISORDERS THAT MAY CAUSE ACUTE PSYCHOSIS

Metabolic Disorders
Hypercalcemia.
Hypercarbia.
Hypoglycemia.
Hyponatremia.
Hypoxia.
Inflammatory Disorders
Sarcoidosis.
Systemic lupus erythematosus.
Temporal (giant cell) arteritis.
Organ Failure
Hepatic encephalopathy.
Uremia.
Neurologic Disorders
Alzheimer disease.
Cerebrovascular disease.
Encephalitis (including HIV infection).
Encephalopathies.
Epilepsy.
Huntington disease.
Multiple sclerosis.
Neoplasms.
Normal-pressure hydrocephalus.
Parkinson disease.
Pick disease.
Wilson disease.
Endocrine disorders
Addison disease.
Cushing disease.
Panhypopituitarism.
Parathyroid disease.
Postpartum psychosis.
Recurrent menstrual psychosis.
Sydenham chorea.
Thyroid disease.
Deficiency States
Niacin.
Thiamine.
Vitamin B_{12} and folate.

PSYCHOSIS, MEDICATION-INDUCED[60]

ICD-10CM #	F10.5	Psychotic disorder due to psychoactive substance use

PHARMACOLOGIC AGENTS THAT MAY CAUSE ACUTE PSYCHOSIS

Antianxiety Agents
Alprazolam.
Chlordiazepoxide.
Clonazepam.
Clorazepate.
Diazepam.
Ethchlorvynol.
Antibiotics
Isoniazid.
Rifampin.
Anticonvulsants
Ethosuximide.
Phenobarbital.
Phenytoin.
Primidone.
Antidepressants
Amitriptyline.
Doxepin.
Imipramine.
Protriptyline.
Trimipramine.
Cardiovascular Drugs
Captopril.
Digitalis.
Disopyramide.
Methyldopa.
Procainamide.
Propranolol.
Reserpine.
Drugs of Abuse
Alcohol.
Amphetamines.
Cannabis.
Cocaine.
Hallucinogens.
Opioids.
Phencyclidine.
Sedative-hypnotics.
Miscellaneous Drugs
Antihistamines.
Antineoplastics.
Bromides.
Cimetidine.
Corticosteroids.
Disulfiram.
Heavy metals.

PTOSIS

ICD-10CM #	H02.409	Unspecified ptosis of unspecified eyelid
	Q10.0	Congenital ptosis
	H02.419	Mechanical ptosis of unspecified eyelid
	H02.429	Myogenic ptosis of unspecified eyelid
	H02.439	Paralytic ptosis unspecified eyelid

Third nerve palsy.
Myasthenia gravis.
Horner syndrome.
Senile ptosis.

PUBERTY, DELAYED[63]

ICD-10CM #	E30.0	Delayed puberty

NORMAL OR LOW SERUM GONADOTROPIN LEVELS

Constitutional delay in growth and development.
Hypothalamic and/or pituitary disorders:
- Isolated deficiency of growth hormone.
- Isolated deficiency of Gn-RH.
- Isolated deficiency of LH and/or FSH.
- Multiple anterior pituitary hormone deficiencies.

Associated with congenital anomalies: Kallmann syndrome; Prader-Willi syndrome; Laurence-Moon-Biedl syndrome; Friedreich ataxia.
Trauma.
Postinfection.
Hyperprolactinemia.
Postirradiation.
Infiltrative disease (histiocytosis).
Tumor.
Autoimmune hypophysitis.
Idiopathic.
Functional:
Chronic endocrinologic or systemic disorders.
Emotional disorders.
Drugs: cannabis.

INCREASED SERUM GONADOTROPIN LEVELS

Gonadal abnormalities:
Congenital:
Gonadal dysgenesis.
Klinefelter syndrome.
Bilateral anorchism.
Resistant ovary syndrome.
Myotonic dystrophy in males.
17-Hydroxylase deficiency in females.
Galactosemia.
Acquired:
Bilateral gonadal failure resulting from trauma or infection or after surgery, irradiation, or chemotherapy.
Oophoritis: isolated or with other autoimmune disorders.
Uterine or vaginal disorders:
Absence of uterus and/or vagina.
Testicular feminization: complete or incomplete androgen insensitivity.

PUBERTY, PRECOCIOUS

ICD-10CM #		
	E25.0	Congenital adrenogenital disorders associated with enzyme deficiency
	E25.8	Other adrenogenital disorders
	E25.9	Adrenogenital disorder, unspecified

Idiopathic.
Congenital virilizing adrenal hyperplasia.
Hypothalamic tumors.
Head trauma.
Hydrocephalus.
Degenerative CNS disease.
Arachnoid cyst.
Sex chromosome abnormalities (e.g., 47, XXY, 48, XXXY).
Perinatal asphyxia.
CNS infection (e.g., meningitis, encephalitis).

PULMONARY CRACKLES

ICD-10CM #	R09.8	Friction sounds, chest

Pneumonia.
Left ventricular failure.
Asbestosis, silicosis, interstitial lung disease.
Chronic bronchitis.
Alveolitis (allergic, fibrosing).
Neoplasm.

PULMONARY CYSTS ON X-RAY[36]

ICD-10CM #	Q33.0	Polycystic lungs, congenital
	J98.4	Pulmonary manifestations

CAUSES OF CYSTS IN THE LUNG ON CHEST RADIOGRAPH

Cystic fibrosis.
Cystic bronchiectasis.
Bronchopulmonary dysplasia (neonate and older).
Tuberculosis (apical thick walled).
Pulmonary abscess (thick wall, fluid level).
Empyema.
Streptococcal pneumatocele (thin wall, postinfective).
Cavitating pneumonia.
Mycetoma (apical cyst with contents).
Cystic congenital adenomatoid malformation (basal cysts of varying size).
Diaphragmatic hernia (cysts of similar size).
Hiatal hernia (posterior).
Morgagni hernia (midline anterior).
Bronchopulmonary sequestration (basal).
Congenital lobar emphysema.
Hydatid disease (in endemic areas).
Kerosene inhalation (pneumatocele).
Histiocytosis and other causes of interstitial disease.

PULMONARY EDEMA, NONCARDIOGENIC[36]

ICD-10CM #	J81.0	Acute pulmonary edema

CAUSES OF NONCARDIOGENIC PULMONARY EDEMA

Adult respiratory distress syndrome.
Drowning.
Asphyxia.
Upper airway obstruction (usually with cardiomegaly).
High altitude.
Increased intracranial pressure.
Postictal.
Noxious gases:
Smoke.
Nitrous dioxide (silo filler's disease).
Sulfur dioxide.
Nitrogen mustard.
Drugs:
Aspirin.
Diazepam, chlordiazepoxide, barbiturates.
Narcotics (heroin, methadone, morphine).
β-adrenergic drugs (terbutaline).
Contrast media.
Colchicine.
Fluorescein.
Hydrochlorothiazide.
Nitrofurantoin.
Propoxyphene.
Poisons:
Parathion.
Transfusion reactions.
Renal failure: transplantation.
Bone marrow transplantation.
Fat embolism.
Pancreatitis.

PULMONARY EOSINOPHILIA[2]

ICD-10CM #	NEC J82	Eosinophilia, pulmonary

TYPES AND CAUSES OF PULMONARY EOSINOPHILIA

Drug- and toxin-induced eosinophilic lung diseases.
Helminth and fungal infection-related eosinophilic lung diseases:
Transpulmonary passage of larvae (i.e., Löffler syndrome): Ascaris, hookworm, Strongyloides.
Pulmonary parenchymal invasion: mostly helminths, paragonimiasis.
Heavy hematogenous seeding with helminths: trichinellosis, disseminated strongyloidiasis, cutaneous and visceral larva migrans, schistosomiasis.
Tropical pulmonary eosinophilia: filaria.
Allergic bronchopulmonary aspergillosis.
Chronic eosinophilic pneumonia.
Acute eosinophilic pneumonia.
Churg-Strauss syndrome (vasculitis).
Other: neoplasia, idiopathic hypereosinophilic syndrome, bronchocentric granulomatosis.

PULMONARY HEMORRHAGE, DIFFUSE, ALVEOLAR[70]

ICD-10CM #	R04.8	Pulmonary hemorrhage

IMMUNOLOGIC DISEASES

Anti–glomerular basement membrane antibody disease (Goodpasture syndrome).
Vasculitides associated with circulating or in situ immune complexes:
Systemic lupus erythematosus.
Mixed connective tissue disease.
Schönlein-Henoch purpura.
Essential mixed cryoglobulinemia.
Tumor-related vasculitis.
Endocarditis-related vasculitis.
Polyarteritis nodosa.
Systemic necrotizing vasculitis.
Vasculitides associated with antineutrophil cytoplasmic antibodies:
Wegener granulomatosis.
Microscopic polyangiitis.
Idiopathic necrotizing crescentic glomerulonephritis.
Rapidly progressive glomerulonephritis.
Associated with other connective tissue diseases, pathophysiology unknown:
Rheumatoid arthritis.
Progressive systemic sclerosis.
Behçet disease.
Associated with other renal diseases.
Immunoglobulin A nephropathy.
Diabetic nephropathy.
Associated with precipitating antibodies to milk (Heiner syndrome).

Idiopathic pulmonary hemosiderosis.
Primary antiphospholipid antibody syndrome.

CHEMICAL OR DRUG-RELATED CAUSES

Amiodarone.
D-Penicillamine.
Isocyanates.
Nitrofurantoin.
Retinoic acid.
Trimellitic anhydride.
"Crack" cocaine.
Sirolimus.
Everolimus.
Propylthiouracil-induced vasculitis.
Erlotinib.
Bevacizumab.
Gemcitabine.
Infliximab.

TRANSPLANT-RELATED CAUSES

Bone marrow transplant.
Renal transplant.
Lung transplant.

BLEEDING DIATHESIS

Thrombocytopenia.
Leukemia with diffuse alveolar damage.
Viral pneumonia.
Bacterial or fungal sepsis.
Radiation.
Chemotherapy toxic to lung.
Blast counts >80,000/μL.
Extrinsic anticoagulants/thrombolytics.
Warfarin overdose.
Tissue plasminogen activator.
Platelet glycoprotein IIb/IIIa inhibitors.
Coagulopathies.
Cirrhosis.
Disseminated intravascular coagulation.

INFECTIONS

Adenovirus.
Aspergillosis (invasive).
Cytomegalovirus.
Dengue.
Hantavirus.
Influenza.
Legionella.
Leptospirosis.
Malaria.
Mycoplasma.
Staphylococcus aureus.

PULMONARY VENOUS HYPERTENSION

Mitral stenosis.
Mitral regurgitation.
Pulmonary capillary hemangiomatosis.
Pulmonary veno-occlusive disease.
Fibrosing mediastinitis.
Congenital heart disease.

DIFFUSE LUNG INJURY

Negative-pressure pulmonary hemorrhage.
Breath-hold diving.
Postictal neurogenic pulmonary edema.

PULMONARY HEMORRHAGE, FOCAL[69]

ICD-10CM # R04.8 Pulmonary hemorrhage

CAUSES OF FOCAL PULMONARY HEMORRHAGE

Iatrogenic Disorders
Bronchoscopy.
Lung biopsy.
Pulmonary artery catheterization.
Transtracheal aspiration.
Radiofrequency ablation.
Brachytherapy.
Infectious Disorders
Lung abscess.
Mycetoma.
Necrotizing pneumonia (*Staphylococcus aureus,* gram-negative aerobes, *Legionella,* Actinomyces species, *Stenotrophomonas, Kytococcus sedentarius,* Leptospira species, *Yersinia pestis, Francisella tularensis*).
Parasitic infection (paragonimiasis, amebiasis, ascariasis, clonorchiasis, echinococcosis, hookworm infestation, strongyloidiasis, trichinosis, schistosomiasis).
Parenchymal fungal infection (aspergillosis, mucormycosis, coccidioidomycosis, histoplasmosis, maduromycosis, botryomycosis).
Tuberculosis (active or inactive).
Viral tracheitis.
Herpetic tracheobronchitis.
Interstitial Lung Diseases
Lymphangioleiomyomatosis.
Sarcoidosis.
Tuberous sclerosis.
Pneumoconiosis.
Langerhans cell granulomatosis.
Miscellaneous Disorders
Amyloidosis.
Bronchogenic cyst.
Broncholithiasis.
Bronchopleural fistula.
Thoracic endometriosis.
Foreign body.
Tracheopathia osteoplastica.
Lipoid pneumonia.
Organophosphate aspiration.
Chronic pancreatitis.
Neoplastic Disorders
Bronchial adenoma.
Lung cancer.
Tracheal tumors (mucoepidermoid, squamous cell, adenoid cystic, glomus).
Pulmonary blastoma.
Pleuropulmonary angiosarcoma.
Sarcoma (synovial, myofibroblastic).
Clear cell tumor.
Metastatic disease (prostate, renal, breast, ovarian).
Tracheobronchial schwannoma.
Pulmonary Airway Diseases
Bronchiectasis.
Bronchitis.
Granulomatous tracheobronchitis (ulcerative colitis, Crohn disease, granulomatosis with polyangiitis).
Cystic fibrosis.
Bullous emphysema.
Traumatic Injury
Blunt chest trauma.
Penetrating injury.
Ruptured bronchus.
Lightning injury.
Thoracic splenosis.
Vascular Disorders
Pulmonary embolism, infarction.
Systemic cholesterol emboli.
Intralobar sequestration.
Pulmonary artery aneurysms.
Behçet disease, Hughes-Stovin syndrome, traumatic pseudoaneurysms.
Acquired arteriovenous malformations.
Osler-Weber-Rendu syndrome (hereditary hemorrhagic telangiectasia).
Takayasu arteritis.
Aortic aneurysms.
Trachea–innominate artery fistulas.
Scimitar syndrome.
Vena cava-bronchial.
Dieulafoy disease of bronchus.
Ventriculopulmonary fistulas.
Hemangioma (sclerosing, cavernous, tracheal).

PULMONARY HEMORRHAGE, PEDIATRIC AGE

ICD-10CM # P26.9 Pulmonary hemorrhage newborn

CAUSES OF PULMONARY HEMORRHAGE (HEMOPTYSIS)

Focal Hemorrhage
Bronchitis and bronchiectasis (especially cystic fibrosis related).
Infection (acute or chronic), pneumonia, abscess.
Tuberculosis.
Trauma.
Pulmonary arteriovenous malformation.
Foreign body (chronic).
Neoplasm including hemangioma.
Pulmonary embolus with or without infarction.
Bronchogenic cysts.
Diffuse hemorrhage
Idiopathic of infancy.
Congenital heart disease (including pulmonary hypertension, venoocclusive disease, congestive heart failure).
Prematurity.
Cow's milk hyperreactivity (Heiner syndrome).
Goodpasture syndrome.
Collagen vascular diseases (systemic lupus erythematosus, rheumatoid arthritis).
Henoch-Schönlein purpura and vasculitic disorders.
Granulomatous disease (Wegener granulomatosis).
Celiac disease.
Coagulopathy (congenital or acquired).
Malignancy.
Immunodeficiency.
Exogenous toxins.
Hyperammonemia.
Pulmonary hypertension.
Pulmonary alveolar hemosiderosis.

Tuberous sclerosis.
Lymphangiomyomatosis or lymphangioleiomyomatosis.
Physical injury or abuse.

PULMONARY HEMORRHAGIC SYNDROMES, DIFFUSE[36]

ICD-10CM # P26.1 Massive pulmonary hemorrhage originating in the perinatal period
R04.8 Pulmonary hemorrhage

CLASSIFICATION OF DIFFUSE PULMONARY HEMORRHAGE SYNDROMES

Non-immunocompromised patients

Antibasement membrane antibody disease/Goodpasture syndrome.
Diseases of presumed immune etiology, with or without nephropathy:
- Systemic lupus erythematosus.
- Rheumatoid arthritis.
- Systemic sclerosis.
- Systemic necrotizing vasculitis.
- Granulomatosis with polyangiitis.
- Microscopic polyarteritis.

Diseases with no known immune etiology:
- Idiopathic pulmonary hemosiderosis.
- Rapidly progressive glomerulonephritis without immune complexes.
- Fibrillary glomerulonephritis.
- Drug-induced (anticoagulants, trimellitic anhydride, cocaine, lymphangiography).
- Valvular heart disease.
- Disseminated intravascular coagulation.
- Acute lung injury.
- Tumors.

Immunocompromised Patients

Blood dyscrasias.
Infection.
Tumors.

PULMONARY INFILTRATES ASSOCIATIONS[64]

ICD-10CM # Varies with specific diagnosis

PULMONARY INFILTRATES AND THEIR ASSOCIATION WITH SPECIFIC INFECTIOUS AND NONINFECTIOUS DISORDERS

Radiologic Sign	Potential Etiologic Disorder(s)
Interstitial infiltrates.	Pulmonary edema.
Diffuse alveolar damage.	Idiopathic pneumonia syndrome. Respiratory virus infection: RSV, parainfluenza virus, influenza virus, adenovirus, enterovirus. Herpesvirus infection: CMV, HSV, VZV, HHV-6. *Pneumocystis* pneumonia.
Focal airspace disease.	Bacterial pneumonia. Fungal pneumonia.
Nodules.	Fungal pneumonia (aspergillosis). *Nocardia* infection. *Legionella* infection. Septic bacterial emboli. Mycobacterial infection (with cavitation). EBV lymphoproliferative disorder. Relapsed malignancy. Pulmonary embolism (pleura based).
Halo sign or air-crescent sign.	Aspergillosis.

CMV, Cytomegalovirus; *EBV,* Epstein-Barr virus; *HHV,* human herpesvirus; *HSV,* herpes simplex virus; *RSV,* respiratory syncytial virus; *VZV,* varicella-zoster virus.

PULMONARY INFILTRATES, IMMUNOCOMPROMISED HOST[91]

ICD-10CM # J82 Pulmonary eosinophilia, not elsewhere classified
J98.4 Other disorders of lung

CAUSES OF PULMONARY INFILTRATES IN THE IMMUNOCOMPROMISED HOST

Infections:
- Bacteria:
  - Gram-positive cocci, especially *Staphylococcus.*
  - Gram-negative bacilli.
  - Mycobacterium tuberculosis.
  - Nontuberculous mycobacteria.
  - *Nocardia.*
- Viruses:

Cytomegalovirus.
Herpesvirus.
- Fungi:
  - *Aspergillus.*
  - *Cryptococcus.*
  - *Candida.*
  - *Mucor.*
  - *Pneumocystis jiroveci.*
- Protozoa:
  - *Toxoplasma gondii* (rare).
- Pulmonary effects of therapy:
  - Chemotherapeutic agents.
  - Radiation therapy.
  - Pulmonary hemorrhage.
  - Congestive heart failure.
  - Disseminated malignancy.
  - Nonspecified interstitial pneumonitis (no defined etiology).

PULMONARY LESIONS

ICD-10CM# J98.4 Other disorders of lung
J70.9 Respiratory conditions due to unspecified external agent
S27.309A Unspecified injury of lung, unspecified, initial encounter

TB.
Legionella pneumonia.
Mycoplasma pneumonia.
Viral pneumonia.
Pneumocystis carinii.
Hypersensitivity pneumonitis.
Aspiration pneumonia.
Fungal disease (aspergillosis, histoplasmosis).
ARDS associated with pneumonia.
Psittacosis.
Sarcoidosis.
Septic emboli.
Metastatic cancer.
Multiple pulmonary emboli.
Rheumatoid nodules.

PULMONARY MASS, SOLITARY, CAUSES[36]

ICD-10CM # R91.1 Solitary pulmonary nodule

CAUSES OF A SOLITARY PULMONARY MASS

Bronchial carcinoma.
Bronchial carcinoid.
Granuloma.
Hamartoma.
Metastasis.
Chronic pneumonia or abscess.
Hydatid cyst.
Pulmonary hematoma.
Bronchocele.
Fungus ball.
Massive fibrosis in coal workers.
Bronchogenic cyst.
Sequestration.
Arteriovenous malformation.
Pulmonary infarct.
Round atelectasis.

PULMONARY MASS, SOLITARY, MIMICS[36]

ICD-10CM # Varies with specific diagnosis

SIMULANTS OF A SOLITARY PULMONARY MASS

Extrathoracic artifacts.
Cutaneous masses.
Bony lesions.
Pleural tumors or plaques.
Encysted pleural fluid.
Pulmonary vessels.

PULMONARY NODULE, SOLITARY

ICD-10CM # J98.4 Other disorders of lung

Bronchogenic carcinoma.
Granuloma from histoplasmosis.
TB granuloma.
Granuloma from coccidioidomycosis.
Metastatic carcinoma.

Bronchial adenoma.
Bronchogenic cyst.
Hamartoma.
AV malformation.
Other: fibroma, intrapulmonary lymph node, sclerosing hemangioma, bronchopulmonary sequestration.

PULMONARY–RENAL SYNDROMES, CAUSES[28]

ICD-10CM # Varies with specific diagnosis

Systemic vasculitis	Anti-GBM disease (Goodpasture). ANCA associated: Granulomatosis with polyangiitis. Microscopic polyarteritis. Churg-Strauss syndrome. Drugs (penicillamine, hydralazine, propylthiouracil). Immune complex disease. Lupus erythematosus. Henoch-Schönlein purpura. Mixed cryoglobulinemia. Rheumatoid vasculitis.
Infection	Severe bacterial pneumonia, postinfectious glomerulonephritis, *Legionella,* hantavirus, opportunistic infection in immunocompromised patients, infective endocarditis.
Pulmonary edema and AKI	Volume overload, severe left ventricular failure.
Multiorgan failure	Acute respiratory distress syndrome and AKI.
Other	Paraquat poisoning, renal vein or IVC thrombosis with pulmonary emboli.

AKI, Acute kidney injury; *ANCA,* anti-neutrophil cytoplasmic antibody; *GBM,* glomerular basement membrane; *IVC,* inferior vena cava.

PULSELESS ELECTRICAL ACTIVITY

ICD-10CM # I46.9 Cardiac arrest, cause unspecified

Hypovolemia.
Hypoxia.
Hyperkalemia.
Acidosis.
Cardiac tamponade.
Tension pneumothorax.
Pulmonary embolus.
Drug overdose.
Hypothermia.

PUPILLARY DILATATION, POOR RESPONSE TO DARKNESS

ICD-10CM # H21.569 Pupillary abnormality, unspecified eye

Drugs (narcotics, general anesthetics, cholinergics).
Acute trauma (spasm from prostaglandin release).
Inflammation, infection (interruption of inhibitory fibers to the Edinger-Westphal nucleus).
Old age (loss of inhibition at midbrain from reticular activating formation).
Horner syndrome (sympathetic neuron interruption).
Adie syndrome tonic pupil.
Lymphoma.
Congenital miosis.

PURPURA

ICD-10CM # D69.2 Other nonthrombocytopenic purpura
D69.0 Allergic purpura
D69.49 Other primary thrombocytopenia
M31.1 Thrombotic microangiopathy

THROMBOTIC

Trauma.
Septic emboli, atheromatous emboli.
DIC.
Thrombocytopenia.
Meningococcemia.
Rocky Mountain spotted fever.
Hemolytic-uremic syndrome.
Viral infection: echo, coxsackie.
Scurvy.
Other: left atrial myxoma, cryoglobulinemia, vasculitis, hyperglobulinemic purpura.

PURPURA, NONPALPABLE[45]

ICD-10CM # D69.2 Other nonthrombocytopenic purpura

INCREASED TRANSMURAL PRESSURE GRADIENT

Acute (Valsalva, coughing, vomiting, high altitude, weight lifting).
Chronic—venous stasis.

DECREASED MECHANICAL INTEGRITY OF MICROCIRCULATION AND SUPPORTING TISSUES

Age related (infancy and actinic purpura).
Glucocorticoid excess—Cushing syndrome and glucocorticoid therapy.
Vitamin C deficiency (scurvy).
Abnormal connective tissue—Ehlers-Danlos syndrome.
Amyloid infiltration of blood vessels.
Colloid milium.
Hormonal—female easy bruising syndrome (purpura simplex).
Lorenzo oil.
MELAS syndrome.

TRAUMA TO BLOOD VESSELS

Physical:
- Injuries.
- Child abuse.
- Factitial purpura.

Ultraviolet purpura:
- Purpuric sunburn.
- Solar purpura.

Infectious:
- Bacterial.
- Rickettsial.
- Fungal.
- Viral.
- Parasitic.

Embolic:
- Infectious organisms.
- Atheroemboli (cholesterol crystal emboli).
- Fat emboli.

Allergic and/or inflammatory:
- Serum sickness.
- Pigmented purpuric eruptions.
- Pyoderma gangrenosum.
- Contact dermatitis.
- Familial Mediterranean fever.

Neoplastic.
Metabolic:
- Erythropoietic porphyria.
- Calciphylaxis.

Immunoglobulin related (hyperglobulinemic purpura of Waldenström and light-chain vasculitis).
Drug related.
Thrombotic:
- Disseminated intravascular coagulation.
- Warfarin (Coumadin)-induced skin necrosis.
- Protein C or protein S deficiency, factor V Leiden, prothrombin G20201A.
- Purpura fulminans.
- Paroxysmal nocturnal hemoglobinuria.
- Antiphospholipid antibody syndrome.
- Hemangioma with thrombocytopenia and consumptive coagulopathy (Kasabach-Merritt syndrome).

UNKNOWN CAUSE—PSYCHOGENIC PURPURA

PURPURA, NONPURPURIC DISORDERS SIMULATING PURPURA[3]

ICD-10CM # Varies with specific diagnosis

Disorders with telangiectasias:
- Cherry angiomas.
- Hereditary hemorrhagic telangiectasia.
- Chronic actinic telangiectasia.
- Scleroderma.
- CREST syndrome.
- Ataxia-telangiectasia.
- Chronic liver disease.
- Pregnancy-related telangiectasia.

Kaposi sarcoma and other vascular sarcomas.
Fabry disease.

Neonatal extramedullary hematopoiesis.
Angioma serpiginosum.

PURPURA, PALPABLE[45]

ICD-10CM # D69.2 Other nonthrombocytopenic purpura

Cutaneous vasculitis:
- Systemic vasculitides.
- Paraneoplastic vasculitis.
- Henoch-Schönlein purpura.
- Acute hemorrhagic edema of infancy.
- Livedoid vasculitis.
- Idiopathic.
- Urticarial.

Cryoglobulinemia.
Cryofibrinogenemia.
Primary cutaneous diseases

QT INTERVAL PROLONGATION[52]

ICD-10CM # R94.31 Abnormal electrocardiogram [ECG] [EKG]
I45.81 Long QT syndrome

Drugs:
- Class I antiarrhythmics (e.g., disopyramide, procainamide, quinidine).
- Class III antiarrhythmics.
- Tricyclic antidepressants.
- Phenothiazines.
- Astemizole.
- Terfenadine.
- Adenosine.
- Antibiotics (e.g., erythromycin and other macrolides):
  - Antifungal agents.
  - Pentamidine, chloroquine.

Ischemic heart disease.
Cerebrovascular disease.
Rheumatic fever.
Myocarditis.
Mitral valve prolapse.
Electrolyte abnormalities.
Hypocalcemia.
Hypothyroidism.
Liquid protein diets.
Organophosphate insecticides.
Congenital prolonged QT syndrome.

RADIATION-INDUCED NEOPLASMS[81]

ICD-10CM # Varies with specific diagnosis

RADIATION-INDUCED NEOPLASMS

Osteochondroma
Benign.
Exclusively with childhood irradiation.
Histologically identical to spontaneous osteochondroma.

Sarcoma
Malignant.
Latent period of 4 years or more.
Histologically identical to spontaneous sarcoma.
Commonly malignant fibrous histiocytoma or osteosarcoma.
Occurs in either bone or soft tissue.

Tumors in Other Organ Systems
Squamous cell cancer of the skin.
Breast cancer.
Leukemia, with shorter latent period than sarcoma.

RECTAL MASS, PALPABLE[86]

ICD-10CM # R22.9 Localized swelling, mass and lump, unspecified

Rectal carcinoma.
Rectal polyp.
Hypertrophied anal papilla.
Diverticular phlegmon (prolapsing into the pouch of Douglas).
Sigmoid colon carcinoma (prolapsing into the pouch of Douglas).
Metastatic deposits at the pelvic reflection (Blumer shelf).
Primary pelvic malignancy (uterine, ovarian, prostatic, or cervical).
Mesorectal lymph nodes.
Endometriosis.
Solitary rectal ulcer syndrome.
Foreign body.
Feces.
Presacral cyst.
Amebic granuloma.
Vaginal tampon and even the pubic bone may be mistaken for a rectal mass.

RECTAL PAIN

ICD-10CM # K62.89 Other specified diseases of anus and rectum

Anal fissure.
Thrombosed hemorrhoid.
Anorectal abscess.
Foreign bodies.
Fecal impaction.
Endometriosis.
Neoplasms (primary or metastatic).
Pelvic inflammatory disease.
Inflammation of sacral nerves.
Compression of sacral nerves.
Prostatitis.
Other: proctalgia fugax, uterine abnormalities, myopathies, coccygodynia.

RED BLOOD CELL APLASIA, ACQUIRED, ETIOLOGY

ICD-10CM # D61.01 Constitutional (pure) red blood cell aplasia

Idiopathic (>50% of cases).
Medications (most frequent with phenytoin).
Non-Hodgkin lymphoma.
Viral infections (parvovirus B19, EB virus, mumps, hepatitis).
Myelodysplastic syndromes.
Thymoma.
Autoimmune diseases.
Allogenic bone marrow transplant from ABO incompatible donor.
Pregnancy.

RED BLOOD CELL FRAGMENTATION HEMOLYSIS, CAUSES[44]

ICD-10CM # Varies with specific disorder

CAUSES OF RED BLOOD CELL FRAGMENTATION HEMOLYSIS

Damaged microvasculature.
Thrombotic thrombocytopenic purpura–hemolytic uremic syndrome (TTP–HUS).
Associated with pregnancy: preeclampsia or eclampsia; hemolysis plus elevated liver enzymes plus low platelets (HELLP syndrome).
Associated with malignancy, with or without mitomycin C treatment.
Vasculitis: polyarteritis, Wegener granulomatosis, acute glomerulonephritis, or *Rickettsia*-like infections.
Systemic lupus erythematosus.
Abnormalities of renal vasculature: malignant hypertension, acute glomerulonephritis, scleroderma, or allograft rejection with or without cyclosporine treatment.
Disseminated intravascular coagulation.
Malignant hypertension.
Catastrophic antiphospholipid antibody syndrome.
Atrioventricular malformations.
Kasabach-Merritt syndrome.
Hemangioendotheliomas.
Atrioventricular shunts for congenital and acquired conditions (e.g., stents, coils, transjugular intrahepatic portosystemic shunt, Levine shunts).
Cardiac abnormalities:
- Replaced valve, prosthesis, graft, or patch.
- Aortic stenosis or regurgitant jets (e.g., in ruptured sinus of Valsalva).

Drugs:
- Cyclosporine.
- Mitomycin.
- Ticlopidine.
- Clopidogrel.
- Tacrolimus.
- Cocaine.

Systemic infection:
- Bacterial endocarditis.
- Brucellosis.
- Cytomegalovirus.
- Human immunodeficiency virus.
- Ehrlichiosis.
- Rocky Mountain spotted fever

RED EYE

ICD-10CM # H57.8 Other specified disorders of eye and adnexa

Infectious conjunctivitis (bacterial, viral).
Allergic conjunctivitis.
Acute glaucoma.
Keratitis (bacterial, viral).
Iritis.
Trauma.

Neonatal extramedullary hematopoiesis.
Angioma serpiginosum.

PURPURA, PALPABLE[45]

ICD-10CM # D69.2 Other nonthrombocytopenic purpura

Cutaneous vasculitis:
- Systemic vasculitides.
- Paraneoplastic vasculitis.
- Henoch-Schönlein purpura.
- Acute hemorrhagic edema of infancy.
- Livedoid vasculitis.
- Idiopathic.
- Urticarial.

Cryoglobulinemia.
Cryofibrinogenemia.
Primary cutaneous diseases

QT INTERVAL PROLONGATION[52]

ICD-10CM # R94.31 Abnormal electrocardiogram [ECG] [EKG]
I45.81 Long QT syndrome

Drugs:
- Class I antiarrhythmics (e.g., disopyramide, procainamide, quinidine).
- Class III antiarrhythmics.
- Tricyclic antidepressants.
- Phenothiazines.
- Astemizole.
- Terfenadine.
- Adenosine.
- Antibiotics (e.g., erythromycin and other macrolides):
  - Antifungal agents.
  - Pentamidine, chloroquine.

Ischemic heart disease.
Cerebrovascular disease.
Rheumatic fever.
Myocarditis.
Mitral valve prolapse.
Electrolyte abnormalities.
Hypocalcemia.
Hypothyroidism.
Liquid protein diets.
Organophosphate insecticides.
Congenital prolonged QT syndrome.

RADIATION-INDUCED NEOPLASMS[81]

ICD-10CM # Varies with specific diagnosis

RADIATION-INDUCED NEOPLASMS

Osteochondroma
Benign.
Exclusively with childhood irradiation.
Histologically identical to spontaneous osteochondroma.

Sarcoma
Malignant.
Latent period of 4 years or more.
Histologically identical to spontaneous sarcoma.
Commonly malignant fibrous histiocytoma or osteosarcoma.
Occurs in either bone or soft tissue.

Tumors in Other Organ Systems
Squamous cell cancer of the skin.
Breast cancer.
Leukemia, with shorter latent period than sarcoma.

RECTAL MASS, PALPABLE[86]

ICD-10CM # R22.9 Localized swelling, mass and lump, unspecified

Rectal carcinoma.
Rectal polyp.
Hypertrophied anal papilla.
Diverticular phlegmon (prolapsing into the pouch of Douglas).
Sigmoid colon carcinoma (prolapsing into the pouch of Douglas).
Metastatic deposits at the pelvic reflection (Blumer shelf).
Primary pelvic malignancy (uterine, ovarian, prostatic, or cervical).
Mesorectal lymph nodes.
Endometriosis.
Solitary rectal ulcer syndrome.
Foreign body.
Feces.
Presacral cyst.
Amebic granuloma.
Vaginal tampon and even the pubic bone may be mistaken for a rectal mass.

RECTAL PAIN

ICD-10CM # K62.89 Other specified diseases of anus and rectum

Anal fissure.
Thrombosed hemorrhoid.
Anorectal abscess.
Foreign bodies.
Fecal impaction.
Endometriosis.
Neoplasms (primary or metastatic).
Pelvic inflammatory disease.
Inflammation of sacral nerves.
Compression of sacral nerves.
Prostatitis.

Allergic conjunctivitis.
Acute glaucoma.
Keratitis (bacterial, viral).
Iritis.
Trauma.

RED EYE, ACUTE[4]

ICD-10CM # H57.8 Other specified disorders of eye and adnexa

Obvious open globe.
Corneal abrasion.
Corneal ulcer.
Subconjunctival hemorrhage.
Hyphema.
Occult open globe.
Herpes simplex virus glaucoma.
Iritis, traumatic iritis.
Scleritis.
Conjunctivitis.
Blepharitis.
Ultraviolet keratitis.
Episcleritis.
Conjunctival foreign body.
Dry eye.
Contact lens overwear syndrome.

RED HOT JOINT

ICD-10CM # Varies with specific diagnosis

Trauma.
Gout.
Infection (septic joint).
Pseudogout (calcium pyrophosphate dehydrate crystal deposition).
Psoriatic arthropathy.
Reactive arthritis.
Palindromic rheumatism.

RED URINE

ICD-10CM # R39.19 Other difficulties with micturition

Hematuria.
Porphyrins.
Hemoglobinuria.
Myoglobinuria.
Medications (phenazopyridine, aminosalicylic acid, deferoxamine, phenazopyridine, phenolphthalein, NSAIDs, rifampin, phenytoin, methyldopa, doxorubicin, phenacetin).
Foods (beets, berries, maize).
Urate crystalluria.

RENAL ALLOGRAFT DYSFUNCTION[34]

ICD-10CM # T86.1 Complications of renal allograft

IMMEDIATE/DELAYED GRAFT FUNCTION (1 TO 3 DAYS)

Acute tubular necrosis.
Hyperacute humoral rejection.
Urinary leak or obstruction.
Renal artery or vein thrombosis.
Recurrence of disease (e.g., focal segmental glomerulosclerosis).

EARLY POSTTRANSPLANTATION PERIOD (FIRST MONTH)

Acute cellular rejection.
Acute humoral rejection.
Calcineurin inhibitor toxicity.
Urinary tract obstruction.
Volume depletion.
Recurrence of disease.

Late Acute Dysfunction

Acute rejection.
Cyclosporine or tacrolimus toxicity.
Recurrence of primary disease.
Tubulointerstitial nephritis, drug-induced.
Renal artery stenosis.
Infection (bacterial urinary tract infection [UTI], cytomegalovirus, BK virus).
Hemodynamic (volume; use of angiotensin-converting enzyme inhibitor, angiotensin II receptor blocker).

Chronic Dysfunction

Chronic rejection.
Cyclosporine or tacrolimus toxicity.
Recurrent renal disease.
De novo renal disease.
Urinary tract obstruction.
Bacterial UTI.
Hypertensive nephrosclerosis.

RENAL ARTERY OCCLUSION, CAUSES

ICD-10CM # N28.0 Ischemia and infarction of kidney

Atrial fibrillation.
Angiography or stent placement.
Abdominal aortic surgery.
Trauma.
Renal artery aneurysm/dissection.
Vasculitis.
Thrombosis in patient with fibromuscular dysplasia.
Atherosclerosis.
Septic embolism.
Mural thrombus thromboembolism.
Atrial myxoma thromboembolism.
Mitral stenosis thromboembolism.
Prosthetic valve thromboembolism.
Renal cell carcinoma.

RENAL COLIC[4]

ICD-10CM # N23 Unspecified renal colic

Vascular:
- Abdominal aortic aneurysm.
- Aortic dissection.
- Renal artery dissection.
- Renal artery stenosis.
- Renal vein thrombosis.
- Renal infarct.
- Mesenteric ischemia.
- Retroperitoneal hemorrhage.

GI:
- Incarcerated hernia.
- Appendicitis.
- Cholecystitis.
- Biliary colic.
- Pancreatitis.
- Bowel obstruction.
- Diverticulitis.

Gynecologic:
- Ectopic pregnancy.
- Ovarian torsion.
- Tuboovarian abscess.
- Pelvic inflammatory disease.
- Endometriosis.

Genitourinary:
- Testicular torsion.
- Pyelonephritis.
- Perinephric abscess.
- Urinary tract tumor.
- Renal papillary necrosis.
- Upper urinary tract hemorrhage.

Musculoskeletal:
- Lumbar strain.
- Radiculopathy.
- Disk herniation.
- Vertebral compression fracture.

Dermatologic:
- Herpes zoster.

Miscellaneous:
- Factitious.

RENAL CYSTIC DISORDERS

ICD-10CM # Q61.01 Congenital single renal cyst

Simple cysts.
Acquired cystic kidney disease.
Autosomal dominant polycystic kidney disease.
Autosomal recessive polycystic kidney disease.
Medullary cystic disease.
Medullary sponge kidney.

RENAL DISEASE, SKIN MANIFESTATIONS[79]

ICD-10CM # Varies with specific diagnosis

SKIN MANIFESTATIONS SECONDARY TO RENAL DISEASE

Nonspecific

Pruritus.
Xerosis.
Acquired ichthyosis.
Pigmentary alteration:
- Pallor (secondary to anemia).
- Hyperpigmentation.
- Dyspigmentation (yellow tint).

Infections (fungal, bacterial, viral).
Purpura.

Somewhat Specific

Acquired perforating dermatosis.
Calciphylaxis.
Metastatic calcification.
Blistering disorders:
- Porphyria cutanea tarda.
- Pseudoporphyria.

Eruptive xanthomas.
Pseudo–Kaposi sarcoma.

Specific

Nephrogenic systemic fibrosis.
Dialysis-associated steal syndrome.
Metastatic renal cell carcinoma.
Dialysis-related amyloidosis.
Arteriovenous shunt dermatitis.
Uremic frost.

RENAL FAILURE, ACUTE, PIGMENT-INDUCED[7]

ICD-10CM # N19 Unspecified kidney failure

CAUSES OF PIGMENT-INDUCED ACUTE RENAL FAILURE

Rhabdomyolysis and myoglobinuria.
Vigorous exercise.
Arterial embolization.
Status epilepticus.
Status asthmaticus.
Coma-induced and pressure-induced myonecrosis.
Heat stress.
Diabetic ketoacidosis.
Myopathy.
Alcoholism.
Hypokalemia.
Hypophosphatemia.
Hemoglobinuria.
Transfusion reactions.
Snake envenomation.
Malaria.
Mechanical destruction of RBCs by prosthetic valves.
G6PD deficiency.

G6PD, Glucose-6-phosphate dehydrogenase; *RBCs,* red blood cells.

RENAL FAILURE, CHRONIC[34]

ICD-10CM # N18.9 Chronic kidney disease, unspecified

CAUSES OF CHRONIC RENAL FAILURE

Diabetic glomerulosclerosis (systemic disease involving the kidney).
Hypertensive nephrosclerosis.
Glomerular disease:
- Glomerulonephritis.
- Amyloidosis, light chain disease (systemic disease involving the kidney).
- Systemic lupus erythematosus, Wegener granulomatosis (systemic disease involving the kidney).

Tubulointerstitial disease:
- Reflux nephropathy (chronic pyelonephritis).
- Analgesic nephropathy.
- Obstructive nephropathy (stones, benign prostatic hypertrophy).
- Myeloma kidney (systemic disease involving the kidney).

Vascular disease:
- Scleroderma (systemic disease involving the kidney).
- Vasculitis (systemic disease involving the kidney).
- Renovascular renal failure (ischemic nephropathy).
- Atheroembolic renal disease (systemic disease involving the kidney).

Cystic disease:
- Autosomal dominant polycystic kidney disease.
- Medullary cystic kidney disease.

RENAL FAILURE, INTRINSIC OR PARENCHYMAL CAUSES[82]

ICD-10CM #
- N17.0 Acute kidney failure with tubular necrosis
- N17.1 Acute kidney failure with acute cortical necrosis
- N17.2 Acute kidney failure with medullary necrosis
- N17.8 Other acute kidney failure
- N17.9 Acute kidney failure, unspecified
- N18.9 Chronic kidney disease, unspecified

ABNORMALITIES OF THE VASCULATURE

Renal arteries: atherosclerosis, thromboembolism, arteritis.
Renal veins: thrombosis.
Microvasculature: vasculitis, thrombotic microangiopathy.

ABNORMALITIES OF GLOMERULI (ACUTE GLOMERULONEPHRITIS)

Antiglomerular membrane disease (Goodpasture syndrome).
Immune complex glomerulonephritis: SLE, postinfectious, idiopathic, membranoproliferative.

ABNORMALITIES OF INTERSTITIUM (ACUTE INTERSTITIAL NEPHRITIS)

Drugs (e.g., antibiotics, NSAIDs, diuretics, anticonvulsants, allopurinol).
Infectious pyelonephritis.
Infiltrative: lymphoma, leukemia, sarcoidosis.

ABNORMALITIES OF TUBULES

Physical obstruction (uric acid, oxalate, light chains).
Acute tubular necrosis:
- Ischemic.
- Toxic (antibiotics, chemotherapy, immunosuppressives, radiocontrast dyes, heavy metals, myoglobin, hemolyzed RBCs).

RENAL FAILURE, POSTRENAL CAUSES[82]

ICD-10CM #
- N17.0 Acute kidney failure with tubular necrosis
- N17.1 Acute kidney failure with acute cortical necrosis
- N17.2 Acute kidney failure with medullary necrosis
- N17.8 Other acute kidney failure
- N17.9 Acute kidney failure, unspecified
- N18.9 Chronic kidney disease, unspecified

URETER AND RENAL PELVIS

Intrinsic obstruction:
- Blood clots.
- Stones.
- Sloughed papillae: diabetes, sickle cell disease, analgesic nephropathy.
- Inflammatory: fungus ball.

Extrinsic obstruction:
- Malignancy.
- Retroperitoneal fibrosis.
- Iatrogenic: inadvertent ligation of ureters.

BLADDER

Prostatic hypertrophy or malignancy.
Neuropathic bladder.
Blood clots.
Bladder cancer.
Stones.

URETHRAL

Strictures.
Congenital valves.

RENAL FAILURE, PRERENAL CAUSES[82]

ICD-10CM #
- N17.0 Acute kidney failure with tubular necrosis
- N17.1 Acute kidney failure with acute cortical necrosis
- N17.2 Acute kidney failure with medullary necrosis
- N17.8 Other acute kidney failure
- N17.9 Acute kidney failure, unspecified
- N18.9 Chronic kidney disease, unspecified

DECREASED CARDIAC OUTPUT

CHF.
Arrhythmias.
Pericardial constriction or tamponade.
Pulmonary embolism.

HYPOVOLEMIA

GI tract loss (vomiting, diarrhea, nasogastric suction).
Blood losses (trauma, GI tract surgery).
Renal losses (diuretics, mineralocorticoid deficiency, postobstructive diuresis).
Skin losses (burns).

VOLUME REDISTRIBUTION (DECREASE IN EFFECTIVE BLOOD VOLUME)

Hypoalbuminemic states (cirrhosis, nephrosis).
Sequestration of fluid in "third" space (ischemic bowel, peritonitis, pancreatitis).
Peripheral vasodilation (sepsis, vasodilators, anaphylaxis).

ALTERED RENAL VASCULAR RESISTANCE

Increase in afferent vascular resistance (NSAIDs, liver disease, sepsis, hypercalcemia, cyclosporine).
Decrease in efferent arteriolar tone (ACE inhibitors).

RENAL INFARCTION[28]

ICD-10CM # N28.0 Ischemia and infarction of kidney

CAUSES OF RENAL INFARCTION

Thrombosis: Spontaneous
Atherosclerotic disease of aorta and renal artery.
Fibromuscular dysplasia of renal artery.
Aneurysms of aorta or renal artery.
Dissection of aorta or renal artery:
- Marfan syndrome.
- Ehlers-Danlos syndrome.

Vasculitis involving renal artery:
- Polyarteritis nodosa.
- Takayasu arteritis.
- Kawasaki disease.
- Thromboangiitis obliterans.
- Other necrotizing vasculitides.

Inflammatory disease of the aorta or renal artery:
- Syphilis.
- Tuberculosis.
- Mycoses.

Hypercoagulable states:
- Nephrotic syndrome.
- Antiphospholipid syndrome.
- Antithrombin III deficiency.
- Homocystinuria.

Thrombotic microangiopathies:
- Hemolytic-uremic syndrome.
- Thrombotic thrombocytopenic purpura.
- Antiphospholipid syndrome.
- Malignant hypertension.
- Scleroderma.
- Sickle cell nephropathy.
- Polycythemia vera.
- Postpartum hemolytic-uremic syndrome.
- Hyperacute vascular allograft rejection.

Thrombosis: Induced
Traumatic.
Following endovascular intervention.
Post renal transplantation.
Embolism
Cardiac source:
- Atrial fibrillation or other arrhythmias.
- Native and prosthetic valvular heart disease.
- Infective endocarditis.
- Marantic endocarditis.

Myocardial infarction with mural thrombi.
Left atrial myxoma or other tumor.
Noncardiac sources:
- Atheromatous embolic disease.
- Paradoxical emboli.
- Fat emboli.
- Tumor emboli.

Therapeutic renal embolization.
Segmental renal infarction of childhood.
Cisplatinum and gemcitabine.
Sickle cell disease or sickle cell trait.

RENAL PARENCHYMAL DISEASE, CHRONIC[36]

ICD-10CM # N28.9 Disorder of kidney and ureter, unspecified

DIFFERENTIAL DIAGNOSIS OF CHRONIC RENAL PARENCHYMAL DISEASE

No Papillary/Caliceal Abnormality
Diffuse Parenchymal Loss
Bilateral:
- Chronic glomerulonephritis.
- Diffuse small-vessel disease.
- Hereditary nephropathies.

Unilateral:
- Renal artery stenosis.
- Postirradiation.
- Rare:
  - Hypoplastic kidney.
  - Postobstructive atrophy.

FOCAL PARENCHYMAL LOSS

Infarct.
Previous trauma.
Papillary/Caliceal Abnormality
Diffuse Parenchymal Loss
Obstructive nephropathy.
Generalized reflux nephropathy.
No Parenchymal Loss
Papillary necrosis.
TB.
Medullary sponge kidney.
Megacalices.
Pelvicaliceal cyst.
Focal Parenchymal Loss
Focal reflux nephropathy (chronic atrophic pyelonephritis).
TB.
Calculus disease.

RENAL VEIN THROMBOSIS, CAUSES

ICD-10CM # I82.3 Embolism and thrombosis of renal vein

Nephrotic syndrome.
Renal cell carcinoma.
Aortic aneurysm causing compression.
Lymphadenopathy.
Retroperitoneal fibrosis.
Estrogen therapy.
Pregnancy.
Renal cell carcinoma with vein invasion.
Severe dehydration.

RESPIRATORY DISTRESS IN THE NEWBORN, CAUSES[30]

ICD-10CM # J96.00 Acute respiratory failure

RESPIRATORY DISTRESS IN THE NEWBORN

Noncardiopulmonary
Hypothermia or hyperthermia.
Hypoglycemia.
Metabolic acidosis.
Drug intoxications; withdrawal.
Polycythemia.
CNS insult.
Asphyxia.
Hemorrhage.
Neuromuscular disease.
Werdnig-Hoffman disease.
Myopathies.
Phrenic nerve injury.
Skeletal abnormalities.
Asphyxiating thoracic dystrophy.
Cardiovascular
Left-sided outflow obstruction.
Hypoplastic left heart.
Aortic stenosis.
Coarctation of the aorta.
Cyanotic lesions.
Transposition of the great vessels.
Total anomalous pulmonary venous return.
Tricuspid atresia.
Right-sided outflow obstruction.
Pulmonary
Upper airway obstruction.
Choanal atresia.
Vocal cord paralysis.
Meconium aspiration.
Clear fluid aspiration.
Transient tachypnea.
Pneumonia.
Pulmonary hypoplasia.
Primary.
Secondary.
Hyaline membrane disease.
Pneumothorax.
Pleural effusions.
Mass lesions.
Lobar emphysema.
Cystic adenomatoid malformation.

RESPIRATORY FAILURE, HYPOVENTILATORY[65]

ICD-10CM # J96.00 Acute respiratory failure, unspecified whether with hypoxia or hypercapnia
J96.90 Respiratory failure, unspecified, unspecified whether with hypoxia or hypercapnia

ABNORMAL RESPIRATORY CAPACITY (NORMAL RESPIRATORY WORKLOADS)

Acute depression of CNS:
- Various causes.

Chronic central hypoventilation syndromes:
- Obesity-hypoventilation syndrome.
- Sleep apnea syndrome.
- Hypothyroidism.
- Shy-Drager syndrome (multisystem atrophy syndrome).

Acute toxic paralysis syndromes:
- Botulism.
- Tetanus.
- Toxic ingestion or bites.
- Organophosphate poisoning.

Neuromuscular disorders (acute and chronic):
- Myasthenia gravis.
- Guillain-Barré syndrome.
- Drugs.
- Amyotrophic lateral sclerosis.
- Muscular dystrophies.
- Polymyositis.
- Spinal cord injury.
- Traumatic phrenic nerve paralysis.

ABNORMAL PULMONARY WORKLOADS

Chronic obstructive pulmonary disease:
- Chronic bronchitis.
- Asthmatic bronchitis.
- Emphysema.

Asthma and acute bronchial hyperreactivity syndromes.
Upper airway obstruction.
Interstitial lung diseases.

ABNORMAL EXTRAPULMONARY WORKLOADS

Chronic thoracic cage disorders:
- Severe kyphoscoliosis.
- After thoracoplasty.
- After thoracic cage injury.

Acute thoracic cage trauma and burns.
Pneumothorax.
Pleural fibrosis and effusions.
Abdominal processes.

RESPIRATORY MUSCLE WEAKNESS[69]

ICD-10CM # Varies with specific diagnosis

CAUSES OF DECREASED RESPIRATORY MUSCLE STRENGTH OR ENDURANCE

Disorders of the phrenic nerve:
- Guillain-Barré syndrome.
- Poliomyelitis.

Respiratory muscle atrophy.
Disorders of neuromuscular transmission:
- Myasthenia gravis.
- Ventilator dependence.
- Malnutrition.
- Myopathy.
- Critical illness polyneuropathy/myopathy.

Altered diaphragmatic force-length relationship:
- Dynamic hyperinflation and diaphragmatic flattening.

RETINOPATHY, HYPERTENSIVE

ICD-10CM # H35.039 Hypertensive retinopathy, unspecified eye

Retinal venous obstruction.
Diabetic retinopathy.
Ocular ischemic syndrome.
Hyperviscosity.
Tortuosity of retinal artery.

RHINITIS

ICD-10CM #

J31.0	Chronic rhinitis
J30.0	Vasomotor rhinitis
J30.1	Allergic rhinitis due to pollen
J30.2	Other seasonal allergic rhinitis
J30.5	Allergic rhinitis due to food
J30.89	Other allergic rhinitis
J30.9	Allergic rhinitis, unspecified

Allergic rhinitis.
Infectious rhinitis.
Vasomotor rhinitis.
Exercise-induced rhinitis.
Emotional rhinitis.
Rhinitis medicamentosa.
Hormone-mediated rhinitis (menses, pregnancy, oral contraceptives, hypothyroidism).
GERD.
Chemical- or irritant-induced rhinitis.
Rhinitis mimics:
- Deviated septum.
- Enlarged adenoids.
- Nasal polyps/tumors.
- Foreign bodies.
- CSF rhinorrhea.
- Sarcoidosis.
- Midline granuloma.
- Granulomatosis with polyangiitis.
- SLE.
- Sjögren syndrome.

RHINITIS, CHRONIC[2]

ICD-10CM # J31.0 Chronic rhinitis

CLASSIFICATION OF CHRONIC RHINITIS

Allergic
Systemic.
Local (entopy).
Work-Related
Irritant.
Corrosive.
Immunologic.
Infectious (Rhinosinusitis)
Allergic.
Nonallergic.
Nonallergic
Idiopathic.
Nonallergic with eosinophilia.
Atrophic.
Primary.
Secondary.
Medication-related.
Topical vasoconstrictors (rhinitis medicamentosa).
Oral medications.
Exercise-induced.
Cold air-induced.
Gustatory.
Hormonal.
Aging.
Systemic diseases.

RHINOSINUSITIS, DIFFERENTIAL DIAGNOSIS[61]

ICD-10CM # Varies with specific diagnosis

DIFFERENTIAL DIAGNOSIS OF RHINOSINUSITIS

Allergic Rhinitis
Seasonal.
Perennial.
Combined seasonal and perennial.
Allergic fungal rhinosinusitis.
Nonallergic Rhinitis
Nonallergic, noninflammatory idiopathic rhinopathy (vasomotor rhinitis).
Nonallergic rhinitis with eosinophilia syndrome (NARES).
Cold dry air-induced rhinitis.
Gustatory rhinitis.
Infectious Rhinosinusitis
Bacterial.
Viral.
Fungal.
Granulomatous.
Drug-Induced Rhinitis
Oral contraceptives.
Various antihypertensives and ocular β-blockers.
Topical decongestants (rhinitis medicamentosa).
Phosphodiesterase-5 antagonists.
Mechanical Causes of Rhinosinusitis
Septal deviation.
Nasal foreign body.
Choanal atresia or stenosis.
Adenoid hypertrophy.
Encephalocele.
Glioma.
Dermoid.
Innate and Acquired Immunity Disorders
Congenital or acquired immunodeficiencies.
Cystic fibrosis.
Immotile cilia syndrome.
Systemic Inflammatory Disorders
Sarcoidosis.
Granulomatosis with polyangiitis.
Vasculitis.
Neoplastic Causes
Benign:
- Polyps.
- Nasopharyngeal angiofibroma.
- Inverting papilloma.

Malignant:
- Adenocarcinoma.
- Squamous cell carcinoma.
- Esthesioneuroblastoma.
- Lymphoma.
- Rhabdomyosarcoma.

RIB DEFECTS ON X-RAY[36]

ICD-10CM # Varies with specific diagnosis

CAUSES OF SUPERIOR MARGINAL RIB DEFECTS

Normal
Isolated defects.
Projectional artifacts (due to lordosis).
Neurologic
Paralytic poliomyelitis.
Quadriparesis.
Collagen Vascular Disease
Rheumatoid arthritis.
SLE.
Systemic sclerosis.
Local Pressure
Chest drainage tube.
Osteochondroma.
Neural tumor.
Coarctation of aorta.
Hyperparathyroidism Miscellaneous
Osteogenesis imperfecta.
Marfan syndrome.

RIB NOTCHING ON X-RAY[36]

ICD-10CM # Varies with specific diagnosis

CAUSES OF INFERIOR RIB NOTCHING

ARTERIAL

AORTIC OBSTRUCTION

Aortic coarctation.
Aortic thrombosis.
Aortitis.

SUBCLAVIAN ARTERY OBSTRUCTION

Blalock-Taussig operation.
Arteritis.
Atherosclerotic occlusion.

PULMONARY OLIGEMIA

Pulmonary atresia.
Tetralogy of Fallot.
Multiple pulmonary arterial stenoses.

Venous

CHRONIC SUPERIOR VENA CAVAL OBSTRUCTION

Arteriovenous
Arteriovenous Malformation
Pulmonary.
Chest wall.
Neural
Neurofibromas

RIGHT AXIS DEVIATION[52]

ICD-10CM # Varies with specific diagnosis

Normal variation.
Right ventricular hypertrophy.
Left posterior fascicular block.
Lateral myocardial infarction.
Pulmonary embolism.
Dextrocardia.
Mechanical shifts or emphysema causing a vertical heart.

SALIVARY GLAND ENLARGEMENT

ICD-10CM # K11.1 Hypertrophy of salivary gland

Neoplasm.
Sialolithiasis.
Infection (mumps, bacterial infection, HIV, TB).
Sarcoidosis.
Idiopathic.
Acromegaly.
Anorexia/bulimia.
Chronic pancreatitis.
Medications (e.g., phenylbutazone).
Cirrhosis.
DM.

SALIVARY GLAND SECRETION, DECREASED

ICD-10CM # K11.7 Disturbances of salivary secretion
R68.2 Dry mouth, unspecified

Medications (antihistamines, antidepressants, neuroleptics, antihypertensives).
Dehydration.
Anxiety.
Sjögren syndrome.
Sarcoidosis.
Mumps.
Amyloidosis.
CNS disorders.
Head and neck radiation.

SCLERODERMA-LIKE SYNDROMES[3]

ICD-10CM # Varies with specific diagnosis

OTHER DISEASES

Morphea.
Eosinophilic fasciitis.
Scleredema (of Buschke).
Scleromyxedema.
Graft-versus-host disease.
Nephrogenic-fibrosing dermopathy.

ENVIRONMENTAL AGENTS AND DRUGS

Bleomycin.
l-Tryptophan.
Organic solvents.
Pentazocine.
Toxic oil syndrome.
Vinyl chloride disease.
Gadolinium.

SCROTAL CALCIFICATIONS[74]

ICD-10CM # Varies with specific diagnosis

SCROTAL CALCIFICATIONS

Testicular
Solitary, postinflammatory granulomatous, vascular.
Microlithiasis.
"Burned-out" germ cell tumor.
Large-cell calcifying Sertoli cell tumor.
Teratoma.
Mixed germ cell tumor.
Sarcoid.
TB.
Chronic infarct
Extratesticular
Tunica vaginalis "scrotal pearls"
Chronic epididymitis
Schistosomiasis

SCROTAL MASSES, BOYS AND ADOLESCENTS[53]

ICD-10CM # R22.9 Localized swelling, mass and lump, unspecified

PAINFUL

Testicular torsion.
Torsion of appendix testis.
Epididymitis.
Trauma: ruptured testis, hematocele.
Inguinal hernia (incarcerated).
Mumps orchitis.

PAINLESS

Hydrocele.
Inguinal hernia.[41]
Varicocele.
Spermatocele.
Testicular tumor.
Henoch-Schönlein purpura.
Idiopathic scrotal edema.

SCROTAL PAIN[65]

ICD-10CM#		
	S31.30XA	Unspecified open wound of scrotum and testes, initial encounter
	N50.9	Disorder of male genital organs, unspecified
	R10.2	Pelvic and perineal pain
	N49.9	Inflammatory disorder of unspecified male genital organ
	N50.1	Vascular disorders of male genital organs
	N49.9	Inflammatory disorder of unspecified male genital organ

Torsion:
  Appendages.
  Spermatic cord.
Infection:
  Orchitis.
  Abscess.
  Epididymitis.
Neoplasia:
  Benign.
  Malignant.
Incarcerated hernia.
Trauma.
Hydrocele.
Spermatocele.
Varicocele.

[41] May be associated with discomfort.

SCROTAL PAIN, ADOLESCENT OR PEDIATRIC PATIENT[90]

ICD-10CM # Varies with specific diagnosis

DIFFERENTIAL DIAGNOSIS OF PEDIATRIC ADOLESCENT ACUTE SCROTAL PAIN

Appendage torsion:
  Appendix testis.
  Other appendage (epididymis, paradidymis, vas aberrans).
Spermatic cord torsion:
  Intravaginal, acute or intermittent.
  Extravaginal.
Epididymitis:
  Infectious:
    Urinary tract infection.
    Sexually transmitted disease.
    Viral.
  Sterile or traumatic.
Scrotal edema or erythema:

RIB NOTCHING ON X-RAY[36]

ICD-10CM # Varies with specific diagnosis

CAUSES OF INFERIOR RIB NOTCHING

ARTERIAL

AORTIC OBSTRUCTION

Aortic coarctation.
Aortic thrombosis.
Aortitis.

SUBCLAVIAN ARTERY OBSTRUCTION

Blalock-Taussig operation.
Arteritis.
Atherosclerotic occlusion.

PULMONARY OLIGEMIA

Pulmonary atresia.
Tetralogy of Fallot.
Multiple pulmonary arterial stenoses.

Venous

CHRONIC SUPERIOR VENA CAVAL OBSTRUCTION

Arteriovenous
Arteriovenous Malformation
Pulmonary.
Chest wall.
Neural
Neurofibromas

RIGHT AXIS DEVIATION[52]

ICD-10CM # Varies with specific diagnosis

Normal variation.
Right ventricular hypertrophy.
Left posterior fascicular block.
Lateral myocardial infarction.
Pulmonary embolism.
Dextrocardia.
Mechanical shifts or emphysema causing a vertical heart.

SALIVARY GLAND ENLARGEMENT

ICD-10CM # K11.1 Hypertrophy of salivary gland

Neoplasm.
Sialolithiasis.
Infection (mumps, bacterial infection, HIV, TB).
Sarcoidosis.
Idiopathic.
Acromegaly.
Anorexia/bulimia.
Chronic pancreatitis.
Medications (e.g., phenylbutazone).
Cirrhosis.
DM.

SALIVARY GLAND SECRETION, DECREASED

ICD-10CM # K11.7 Disturbances of salivary secretion
R68.2 Dry mouth, unspecified

Medications (antihistamines, antidepressants, neuroleptics, antihypertensives).
Dehydration.
Anxiety.
Sjögren syndrome.
Sarcoidosis.
Mumps.
Amyloidosis.
CNS disorders.
Head and neck radiation.

[41] May be associated with discomfort.

SCROTAL PAIN, ADOLESCENT OR PEDIATRIC PATIENT[90]

ICD-10CM # Varies with specific diagnosis

DIFFERENTIAL DIAGNOSIS OF PEDIATRIC ADOLESCENT ACUTE SCROTAL PAIN

Appendage torsion:
  Appendix testis.
  Other appendage (epididymis, paradidymis, vas aberrans).
Spermatic cord torsion:
  Intravaginal, acute or intermittent.
  Extravaginal.
Epididymitis:
  Infectious:
    Urinary tract infection.
    Sexually transmitted disease.
    Viral.
  Sterile or traumatic.
Scrotal edema or erythema:

Diaper dermatitis, insect bite, or other skin lesions.
Idiopathic scrotal edema.
Orchitis:
Associated with epididymitis with or without abscess.
Vasculitis (e.g., Henoch-Schönlein purpura).
Viral illness (mumps).
Trauma:
Hematocele or scrotal contusion or testis rupture.
Hernia or hydrocele:
Inguinal hernia with or without incarceration.
Communicating hydrocele.
Encysted hydrocele with or without torsion.
Associated with acute abdominal pathology (e.g., appendicitis, peritonitis).
Varicocele.
Intrascrotal mass:
Cystic dysplasia or tumor of testis.
Epididymal cyst, spermatocele or tumor.
Other paratesticular tumors.
Musculoskeletal pain from inguinal tendonitis or muscle strain.
Referred pain (e.g., ureteral calculus or anomaly).

SCROTAL SWELLING

ICD-10CM # N50.8 Other specified disorders of male genital organs

Hydrocele.
Varicocele.
Neoplasm.
Acute epididymitis.
Orchitis.
Trauma.
Hernia.
Torsion of spermatic cord.
Torsion of epididymis.
Torsion of testis.
Insect bite.
Folliculitis.
Sebaceous cyst.
Thrombosis of spermatic vein.
Other: lymphedema, dermatitis, fat necrosis, Henoch-Schönlein purpura, idiopathic scrotal edema.

SEIZURE

ICD-10CM # R56.9 Unspecified convulsions

Syncope.
Alcohol abuse/withdrawal.
TIA.
Hemiparetic migraine.
Psychiatric disorders.
Carotid sinus hypersensitivity.
Hyperventilation, prolonged breath holding.
Hypoglycemia.
Narcolepsy.
Movement disorders (tics, hemiballismus).
Hyponatremia.
Brain tumor (primary or metastatic).
Tetanus.
Strychnine, phencyclidine poisoning.

SEIZURE, PEDIATRIC[7]

ICD-10CM # R56.9 Unspecified convulsions
P90 Convulsions of newborn

FIRST MONTH OF LIFE

First Day
Hypoxia.
Drugs.
Trauma.
Infection.
Hyperglycemia.
Hypoglycemia.
Pyridoxine deficiency.
Day 2 to 3
Infection.
Drug withdrawal.
Hypoglycemia.
Hypocalcemia.
Developmental malformation.
Intracranial hemorrhage.
Inborn error of metabolism.
Hyponatremia or hypernatremia.
Day >4
Infection.
Hypocalcemia.
Hyperphosphatemia.
Hyponatremia.
Developmental malformation.
Drug withdrawal.
Inborn error of metabolism.

1 TO 6 MO

As above.

6 MO TO 3 YR

Febrile seizures.
Birth injury.
Infection.
Toxin.
Trauma.
Metabolic disorder.
Cerebral degenerative disease.

>3 YR

Idiopathic.
Infection.
Trauma.
Cerebral degenerative disease.

SEIZURE MIMICS[3]

ICD-10CM # Varies with specific diagnosis

NON-EPILEPTIC EPISODIC DISORDERS THAT MAY RESEMBLE SEIZURES

Movement disorders: myoclonus, paroxysmal choreoathetosis, episodic ataxias, hyperexplexia (startle disease).
Migraine: confusional, vertebrobasilar, visual auras.
Syncope.
Behavioral and psychiatric: psychogenic nonepileptic attacks (pseudoseizures), hyperventilation syndrome, panic or anxiety disorder, dissociative states.
Cataplexy (usually associated with narcolepsy).
Transient ischemic attack.
Alcoholic blackouts.
Hypoglycemia.

SEXUAL DIFFERENTIATION ABNORMALITIES[90]

ICD-10CM # Varies with specific diagnosis

ABNORMAL SEXUAL DIFFERENTIATION

Disorders of gonadal differentiation.
Seminiferous tubule dysgenesis.
Klinefelter syndrome.
46,XX male.
Syndromes of gonadal dysgenesis:
Turner syndrome.
Pure gonadal dysgenesis.
Mixed gonadal dysgenesis.
Partial gonadal dysgenesis (dysgenetic male pseudohermaphroditism).
Bilateral vanishing testis, testicular regression syndromes.
Ovotesticular DSD (true hermaphroditism).
46,XX DSD (masculinized female):
Congenital adrenal hyperplasia (21-hydroxylase, 11β-hydroxylase, 3β-hydroxysteroid dehydrogenase deficiencies).
Maternal androgens.
46,XY DSD (undermasculinized male).
Leydig cell agenesis, unresponsiveness.
Disorders of testosterone biosynthesis.
Variants of congenital adrenal hyperplasia affecting corticosteroid and testosterone synthesis:
StAR deficiency (congenital lipoid adrenal hyperplasia).
Cytochrome P450 oxidoreductase (POR) deficiency.
3β-Hydroxysteroid dehydrogenase deficiency.
17β-Hydroxylase deficiency.
Disorders of testosterone biosynthesis:
17,20-Lyase deficiency.
17β-Hydroxysteroid oxidoreductase deficiency.
Disorders of androgen-dependent target tissue:
Androgen receptor and postreceptor defects.
Syndrome of complete (severe) androgen insensitivity.
Syndrome of partial androgen insensitivity.
Mild androgen insensitivity syndrome (MAIS).
Disorders of testosterone metabolism by peripheral tissues:
5α-Reductase deficiency.
Disorders of synthesis, secretion, or response to müllerian-inhibiting substance.
Persistent müllerian duct syndrome.
Unclassified forms:
In females: Mayer-Rokitansky-Küster-Hauser syndrome.
Disorder of sex development (DSD).

SEXUAL DYSFUNCTION, FEMALE[3]

ICD-10CM # R37 Sexual dysfunction, unspecified

FACTORS THAT MAY INFLUENCE SEXUAL FUNCTIONING IN WOMEN

Biological

Medications (e.g., antidepressants, antihypertensives).
Vaginal atrophy, pain with intercourse.
Low testosterone levels (e.g., bilateral oophorectomy).
Illness (e.g., diabetes, hypothyroidism, cerebrovascular accident).
Sleep disturbances, fatigue.
Disability or pain from illness (e.g., arthritis).
Incontinence.

Psychological

Depression.
Body image.

Interpersonal

Marital issues.
Poor communication.
Partner's sexual problems (e.g., erectile dysfunction).
Partner's health problems (e.g., myocardial infarction).

Sociocultural

Ageism ("too old" to want sex).
Multiple other obligations and commitments.
Lack of partner.

SEXUALLY TRANSMITTED DISEASES, ANORECTAL REGION[60]

ICD-10CM #		
	K62.89	Other specified diseases of anus and rectum

ULCERATIVE

Lymphogranuloma venereum.
Herpes simplex virus.
Early (primary) syphilis.
Chancroid (*Haemophilus ducreyi*).
Cytomegalovirus.
Idiopathic (usually HIV positive).

NONULCERATIVE

Condyloma acuminatum.
Gonorrhea.
Chlamydia *(Chlamydia trachomatis).*
Syphilis.

SEXUAL PRECOCITY[94]

ICD-10CM #		
	E30.1	Precocious puberty
	E30.8	Other disorders of puberty

TRUE PRECOCIOUS PUBERTY

Premature reactivation of LHRH pulse generator.

INCOMPLETE SEXUAL PRECOCITY

(Pituitary gonadotropin independent).

Males

Chorionic gonadotropin-secreting tumor.
Leydig cell tumor.
Familial testotoxicosis.
Virilizing congenital adrenal hyperplasia.
Virilizing adrenal tumor.
Premature adrenarche.

Females

Granulosa cell tumor (follicular cysts may be manifested similarly).
Follicular cyst.
Feminizing adrenal tumor.
Premature thelarche.
Premature adrenarche.
Late-onset virilizing congenital adrenal hyperplasia.

In Both Sexes

McCune-Albright syndrome.
Primary hypothyroidism.

SHOULDER PAIN

ICD-10CM #		
	M24.819	Other specific joint derangements of unspecified shoulder, not elsewhere classified
	M75.80	Other shoulder lesions, unspecified shoulder
	S43.409A	Unspecified sprain of unspecified shoulder joint, initial encounter
	S46.919A	Strain of unspecified muscle, fascia and tendon at shoulder and upper arm level, unspecified arm, initial encounter

WITH LOCAL FINDINGS IN SHOULDER

Trauma: contusion, fracture, muscle strain, trauma to spinal cord.
Arthrosis, arthritis, RA, ankylosing spondylitis.
Bursitis, synovitis, tendinitis, tenosynovitis.
Aseptic (avascular) necrosis.
Local infection: septic arthritis, osteomyelitis, abscess, herpes zoster, TB.

WITHOUT LOCAL FINDINGS IN SHOULDER

Cardiovascular disorders: ischemic heart disease, pericarditis, aortic aneurysm.
Subdiaphragmatic abscess, liver abscess.
Cholelithiasis, cholecystitis.
Pulmonary lesions: apical bronchial carcinoma, pleurisy, pneumothorax, pneumonia.
GI lesions: PUD, gastric neoplasm, peptic esophagitis.
Pancreatic lesions: carcinoma, calculi, pancreatitis.
CNS abnormalities: neoplasm, vascular abnormalities.
Multiple sclerosis.
Syringomyelia.
Polymyositis/dermatomyositis.
Psychogenic.
Polymyalgia rheumatica.
Ectopic pregnancy.

SHOULDER PAIN BY LOCATION

ICD-10CM #		
	M75.80	Other shoulder lesions, unspecified shoulder
	S43.499A	Other sprain of unspecified shoulder joint, initial encounter
	S46.019A	Strain of muscle(s) and tendon(s) of the rotator cuff of unspecified shoulder, initial encounter
	S46.819A	Strain of other muscles, fascia and tendons at shoulder and upper arm level, unspecified arm, initial encounter

TOP OF SHOULDER (C4)

Cervical source.
Acromioclavicular.
Sternoclavicular.
Diaphragmatic.

SUPEROLATERAL (C5)

Rotator cuff tendinitis.
Impingement.
Adhesive capsulitis.
Glenohumeral arthritis.

ANTERIOR

Bicipital tendinitis and rupture.
Glenoid labral tear.
Adhesive capsulitis.
Glenohumeral arthritis.
Osteonecrosis.

AXILLARY

Neoplasm (Pancoast, mediastinal).
Herpes zoster.

SHOULDER PAIN, IN DIFFERENT AGE GROUPS[18]

ICD-10CM #		
	M25.519	Pain in unspecified shoulder

COMMON CAUSES OF SHOULDER PAIN IN DIFFERENT AGE GROUPS

Childhood (2 to 10 yr)

Intraarticular

Instability.

Periarticular

Osteochondromas.

Adolescence (10 to 18 yr)

Intraarticular

Instability.

Early Adulthood (18 to 30 yr)

Intraarticular

Instability.
Acromioclavicular joint sprain.

Periarticular
Calcific tendonitis.
Impingement.
Referred
Cervical.
Adulthood (30 to 60 yr)
Intraarticular
Osteochondritis.
Osteoarthritis.
Frozen shoulder.
Inflammatory arthritis.
Periarticular
Calcific tendonitis.
Impingement.
Rotator cuff tear.
Bicipital tendonitis.
Referred
Cervical.
Old Age (>60 yr)
Intraarticular
Osteochondritis.
Osteoarthritis.
Frozen shoulder.
Inflammatory arthritis.
Periarticular
Impingement.
Rotator cuff tear.
Referred
Cervical.

SINUS NODE DYSFUNCTION[34]

ICD-10CM # Varies with specific diagnosis

CAUSES OF SINUS NODE DYSFUNCTION

Intrinsic
Hypothyroidism.
Fibrocalcific degeneration.
Increased vagal tone, especially in sleep apnea.
Congenital mutations.
Scleroderma.
Amyloidosis.
Chagas disease.
Extrinsic
Trauma, including cardiac surgery.
Drugs:
- Calcium-channel blockers.
- β-Blockers.
- Digoxin.
- Antiarrhythmic medications (amiodarone, dronedarone, sotalol, flecainide, propafenone).
- Lithium.

SINUS OSTIAL OBSTRUCTION[10]

ICD-10CM # Varies with specific diagnosis

FACTORS THAT PREDISPOSE TO SINUS OSTIAL OBSTRUCTION

Mucosal Swelling
Systemic factors:
- Viral upper respiratory infection.
- Allergic inflammation.
- Cystic fibrosis.
- Immune disorders.
- Ciliary dyskinesia.
- Tobacco smoke.

Local insult:
- Facial trauma.
- Swimming, diving.
- Rhinitis medicamentosa.
- Nasal intubation.

Mechanical Obstruction
Choanal atresia.
Deviated septum.
Nasal polyps.
Foreign body.
Tumor.
Ethmoid bullae.

SINUS TACHYCARDIA[69]

ICD-10CM # R00.0 Tachycardia, unspecified

DIFFERENTIAL DIAGNOSIS OF SINUS TACHYCARDIA

Etiologic Category
Specific Disorders
Hemodynamic:
- Heart failure: systolic and diastolic heart failure caused by ischemic, valvular, or nonischemic myopathy.
- Loss of circulating blood volume: GI bleeding, anemia, shifts of intravascular fluid due to changes in colloidal osmotic pressure or inflammation.
- Septic shock: dehydration.
- Vascular shunts: intracardiac as well as aortovenous malformations, fistulas.
- Pulmonary embolism.

Metabolic and neurohumoral:
- Sepsis: infections and inflammatory conditions.
- Hyperthyroidism.
- Paget disease of the bone.
- Pheochromocytoma.
- Carcinoid syndrome.
- Beriberi heart disease.
- Carcinoma.
- Hyperpyrexia.
- Acidosis.
- Exercise.

Pharmacologic:
- Sympathomimetic agents: isoproterenol, epinephrine, or dopamine.
- Vagolytic agents, atropine, scopolamine.
- Vasodilators: nitrates, angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, hydrazine, as well as centrally acting vasodilators.
- Thyroid preparations, caffeine and nicotine.
- Bronchodilators, including theophylline and terbutaline.
- Anesthetic agents, including spinal anesthetics, causing peripheral vasodilation.
- Drugs of abuse: amphetamines, cocaine, "ecstasy," cannabis.

Neurologic/psychological:
- Pain.
- Fear, anxiety, and hysteria.
- Hyper-beta adrenergic phase of neurocardiogenic syncope.
- Autonomic dysfunction such as with diabetes.

SKIN AND RENAL[79]

ICD-10CM # Varies with specific diagnosis

SELECTED CONDITIONS WITH CONCURRENT SKIN AND RENAL INVOLVEMENT

More Common
Lupus erythematosus.
Leukocytoclastic vasculitis.
Henoch-Schönlein purpura.
Mixed cryoglobulinemia.
Diabetes mellitus.
Systemic vasculitis.
Less Common
Nail-patella syndrome.
Hemolytic-uremic syndrome.
Toxic shock syndrome.
Mixed connective tissue disease.
Dermatomyositis.
Rheumatoid arthritis.
Sjögren syndrome.
Dermatitis herpetiformis.
Sarcoidosis.
Systemic sclerosis.
Ulcerative colitis.
Amyloidosis.
Toxic epidermolysis.
Hypothyroidism.
Graves disease.
Fabry disease.
Neurofibromatosis.
Hurler syndrome.
Castleman disease.
Infectious endocarditis.
Staphylococcal scalded skin syndrome (in adults).

SKIN INDURATION, CHRONIC[41]

ICD-10CM # Varies with specific diagnosis

CONDITIONS ASSOCIATED WITH CHRONIC SKIN INDURATION

Systemic sclerosis.
Localized scleroderma.
Scleroderma variants.
Scleredema:
- Scleredema adultorum of Buschke.
- Scleredema diabeticorum.
- Scleredema neonatorum.

Scleromyxedema.
Nephrogenic fibrosing dermopathy.
Eosinophilic syndromes:
- Eosinophilic fasciitis (diffuse fasciitis with eosinophilia, Schulman disease).
- Eosinophilia-myalgia syndrome.
- Toxic oil syndrome.

Chronic graft-versus-host disease.
Pseudoscleroderma (local injection of vitamin K, bleomycin, pentazocine).
Metabolic diseases:
- Porphyria cutanea tarda.
- Phenylketonuria.
- Werner syndrome.
- Acromegaly.

Pachydermoperiostitis.

Polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy (POEMS).
Stiff skin syndrome.
Reflex sympathetic dystrophy.
Hemiplegia.

SMALL BOWEL MASSES[86]

ICD-10CM # Varies with specific diagnosis

Cyst:
  Mesenteric cyst.
Tumor:
  Benign.
  Malignant.
Intussusception.
Inflammation:
  Crohn disease.

SMALL BOWEL OBSTRUCTION[60]

ICD-10CM # K56.5 Intestinal adhesions [bands] with obstruction (postprocedural) (postinfection)
Q41.9 Congenital absence, atresia and stenosis of small intestine, part unspecified

INTRINSIC

Congenital (atresia, stenosis).
Inflammatory (Crohn, radiation enteritis).
Neoplasms (metastatic or primary).
Intussusception.
Traumatic (hematoma).

EXTRINSIC

Hernias (internal and external).
Adhesions.
Volvulus.
Compressing masses (tumors, abscesses, hematomas).

INTRALUMINAL

Foreign body.
Gallstones.
Bezoars.
Barium.
Ascaris infestation.

SMALL INTESTINE ULCERATION

ICD-10CM # K63.3 Ulcer of intestine

Inflammatory bowel disease.
Celiac disease.
Vasculitis, SLE, Behçet syndrome.
Uremia.
Infections *(Campylobacter,* TB, *Yersinia,* parasites, typhoid, cytomegalovirus [CMV], *Clostridium).*
Mesenteric insufficiency.
Neoplasms.
Radiation.
Drugs (salicylates, potassium, indomethacin, antimetabolites).
Meckel diverticulum.
Zollinger-Ellison syndrome.
Lymphocytic enterocolitis.
Stomal ulceration.

SMELL DISTURBANCE

ICD-10CM # R43.8 Other disturbances of smell and taste

Upper respiratory tract infection.
Nasal or paranasal sinus disease.
Exposure to noxious vapors.
Head trauma.
Idiopathic.
Dental caries, periodontal disease.
Medications.

SODIUM RETENTION, RENAL CAUSES[79]

ICD-10CM # Varies with specific diagnosis

CAUSES OF RENAL SODIUM RETENTION

Primary
Oliguric acute kidney injury.
Chronic kidney disease.
Glomerular disease.
Severe bilateral renal artery stenosis.
Na+-retaining tubulopathies (genetic).
Mineralocorticoid excess.
Secondary
Heart failure.
Cirrhosis.
Idiopathic edema.

SOFT TISSUE MASS MIMICKING MALIGNANCY[71]

ICD-10CM # Varies with specific diagnosis

OVERVIEW OF DISEASES THAT CAN PRESENT AS A SOFT TISSUE MASS MIMICKING MALIGNANCY

Etiology	Disease Entity
Trauma:	Muscle contusion. Hematoma. Muscle herniation. Calcific myonecrosis. Hypothenar hammer syndrome. Myositis ossificans.
Metabolic:	Diabetic myopathy. Gout. Pseudogout. Calcific tendinosis.
Congenital:	Accessory muscle.
Infectious:	Necrotizing fasciitis. Abscess. Pyomyositis. Hydatid cystic disease. Cat-scratch disease. Actinomycosis.
Inflammation:	Bursitis. Sarcoidosis. Foreign body reaction. Injection granuloma. Granuloma annulare. Epidermal inclusion cyst.
Vascular:	Adventitial cystic disease. Pseudoaneurysm. Thrombosed vein. Arteriovenous vascular malformation.
Miscellaneous:	Focal myositis. Amyloid tumor of soft tissue.

SOFT TISSUE TUMORS, PEDIATRIC PATIENTS[71]

ICD-10CM # Varies with specific diagnosis

PEDIATRIC SOFT TISSUE TUMORS

Vascular lesions:
  Hemangioma of infancy.*
  Congenital hemangioma.
  Hemangioendothelioma (Kasabach-Merritt syndrome).
  Arteriovenous malformation.
  Venous malformations.
  Lymphatic malformation (lymphangioma, cystic hygroma).
  Capillary malformation.
Adipocytic tumors:
  Lipoma.
  Lipoblastoma.
  Liposarcoma.
Fibrohistiocytic tumors:
  Pigmented villonodular synovitis.
  Giant cell tumor of tendon sheath.
Fibroblastic and myofibroblastic tumors:
  Nodular fasciitis.
  Fibrous hamartoma of infancy.
  Myofibroma, myofibromatosis.
  Infantile fibrosarcoma.
  Fibromatosis colli.
Neurogenic tumors:
  Schwannoma.
  Neurofibroma.
  Malignant nerve sheath tumor.
Leiomyoma
Rhabdomyosarcoma
Tumors of uncertain differentiation
  Synovial cell sarcoma.
  Primitive neuroectodermal tumor (Ewing sarcoma).
Pilomatricoma

*Lesions with MR-specific features.

SORE THROAT[7]

ICD-10CM # J02 Acute pharyngitis

DIFFERENTIAL DIAGNOSIS FOR SORE THROAT

Infectious Causes
Aerobes
Common:
  Streptococcus pyogenes (GABHS).
  GABHS.
  Peptostreptococcus spp.
  Non–group A streptococcus.
  Neisseria gonorrhoeae.
  Neisseria meningitides.
  Mycoplasma pneumoniae.

Arcanobacterium hemolyticum.
Chlamydia trachomatis.
Staphylococcus aureus.
Uncommon:
Haemophilus influenzae.
Haemophilus parainfluenzae.
Coccidioides spp.
Corynebacterium diphtheriae.
Streptococcus pneumoniae.
Yersinia enterocolitica.
Treponema pallidum.
Francisella tularensis.
Legionella pneumophila.
